424 RARE OLD MEDICAL.—MIKPOKOS
MOTPATIA; a Descript. of the Body of Man;
together with the Controversies thereto
belonging, &c., by HELKIAH CROOKE, Dr.
of Physicke, WITH THE FINE OLD ENGR.
COMPARTMT. TITLE, shewing various opera-
tions in progress, &c., and all the curious
copper-plt. vigns. on text, thk. fol.,
contemp. hf. bndg. (covers detached) (size
of ll. 13 by 8½ bare), very fair copy,
1631

Quite perfect as regards text, and has the leaf
of ERRATA at end. DEFECTS:—Slightly water-
stained in places, and top blank mgn. of engr.
title needs reinforcing, as do the lower blank
mgn. of the last leaf of text, do. of Index,
and do. Errata (foxed). AT THE END is:—
An Explanat. of the fashion and use of 53
instruments of Chirurgery, by same author,
with separate vign. title and copperplt. cuts.
The book is dedicated to the Worshipful Co. of
Barber-Chyrurgeons.

A
DESCRIPTION
of the Body of Man.

WITH THE CONTROVERSIES
THERETO BELONGING.

Collected and Translated out of all the Best Authors of Anatomy, Especially out of Gasper Bauhinus and Andreas Laurentius. By HELKIAH CROOKE Doctor of Physicke.

Published by the Kings Maiesties especiall Direction and Warrant according to the first integrity, as it was originally written by the AVTHOR.

The second Edition corrected and enlarged.

Printed at London by Thomas and Richard Cotes, and are to be sold by Michael Sparke, dwelling at the blue Bible in Greeces Arber, 1631.

DESCRIPTION

of the Body of Man.

WITH THE CONTRACTIONS

OF THE MUSCLES.

By WILLIAM SMITH, M.D. F.R.S. &c.

Author of the 'Anatomy of the Human Eye' &c.

London: Printed by J. Smith, 1789.

The Author's Address is at the 'Anatomical Theatre' in St. George's Hospital, London.

TERATISSIMOQVE PRIN-

CIPi AC DOMINO NOSTRO

IACOBO, DEI GRATIA

Magnæ BRITANNIÆ, Franciæ

& Hiberniæ REGI, FIDEI DE.

FENSORI, &c.

T fuscepti moles operis, cui vix
cuiusvis nostrorum hominum vires respondent, &
inassueta scriptioni manus, merito me, dum rem pa-
rarem, deteruere quo minus Augusto tuo nomini
inscriptam vellem; Rex serenissime & tui seculi
longe literatissime, ita demum conscientia animi
integri, sed quorundam (quos minime decuit) ob-
trectatione tentati, ad eam me impulit recte facto-
rum fiduciam, vti primum libenter ad tuâ Maiesta-
tem prouocauerim, quem fælicitas Publica, cum primis Literaria, non Orbis
modo nostri, sed & *ἡ γυμνασιαρχία* Imperio admouit. Enimvero vt taceam eam
quam exteræ Gentes in Tuis egregie scriptis amant & admirantur *πολυμαθία*
σίαν; interior illa *πολυμαθία* quam ante annos aliquot in altera, nouissime in
Cantabrigiensi Academia publicisq; Comitijs sub tuis Auspicijs habitis, sig-
natam exhibuit Maiestas tua; non sinit me dubitare litem hanc de re litera-
ria Tuo Tribunali ordinariè competituram. Duo igitur sunt quæ huic ope-
ri affigunt si non affingunt crimina, mihi ipsi tertium. Primum idq; maxi-
mum, nefas esse ducunt Artis Mystèria ignobili vulgo prostituisse. Secun-
dum, velamen Naturæ reuelare & Pudicitiam quasi in propatulo ponere.
Tertium illiberalis esse ingenij arguunt in aliena quercu lignari. Quæ sin-
gula quidem amoliri, vt mea plurimum interesse sentio, ita supplex obte-
stor Maiestatem tuam, pro eo, quo coronatæ incedunt virtutes tuæ, Can-
dore vt tantisper tua tempora demorer dum totidem momentis molimen-
ta isthæc diruam. Atq; primum me mouit non modo scriptorum Veterum
Græcorum, Latinorum, Arabum recepta consuetudo, qui ad vnum omnes
Artes quisq; suas cuiusvis generis indigitarunt; sed & Neotericorum scho-
la Medicorum, qui Patrio Idiomate vel primum donarunt inventa Anato-
mica vel postea traduxerunt; cuius rei locuples mihi testis est pars quæque

Europæ maxime literata, Hispaniam dico, Gallias, Italiam & vtramq; Germaniam. Neq; vero in nostra Anglia filuit hæc Musa, aut postliminio tantum recepta est, sed superiori seculo nata, sub Patre, Filio, Filia, potentissimis & literatissimis Principibus ter quidem instaurata, sed destituta fomentis in Cunis adhuc vagire deprehenditur: siquidem vt vrbium Imperiorumq; ita literarum sua sunt & lenta tempora quibus oriuntur, florent, senescunt & tandem intereunt. Taceo illa, maxima quidem, sed commemorata nobis libro primo rationum momenta, quibus ab utilitate, a voluptate, a necessitate ipsa, quotquot mortalium sumus, cogimur, trahimur, allicimur in Communionem Naturalis Sacramenti summæ Magni Opificis sapientiæ et bonitatis. Quis ora erecta dedit & oculos versi-colores? quis narium perforationes & sinuosas aurium tornauit Cochleas? quis venarum arteriarumq; riuos & aquæ-ductus distribuit, nervorum terendit rigiditates, ossium ^{θερελινον} posuit, cutis efflorescentiam & membranarum expansa dilatauit? quis artus artuumq; digitos diuisit, firmavit pedes, poros & spiracula terebrauit? quis excauavit pulmonum Bronchos spiritusq; reciprocationes instituit? quis motus cordis geminos, intermediam quietem, & conclusæ vitæ subsultationes pulsusq; limitauit? quis viscerum coagulavit conglomerata Parenchymata? quis Sensuum ^{αισθησεις} Animæ Regiam stipavit, Cerebrum Falce diuisit, arcuatam Concamerationem medullæ, speculumq; lucidum disposuit? quis spirituum Animalium determinauit conceptacula, reticulum mirabile plexumq; Choroidem innexuit? Dies me deficeret si ventriculi Chylosin, intestinorum volumina, Mesaraicarum suctus, hepatis sanguificationem & Anastomoses mirabiles, si lienis defæcationem, renum emulctus, vesicarum collectiones, testium irradiationes, vteri sensus, & mille artes Naturæ minimis particulis ingenitas prædicem: quæ si non singula, at præcipua tamen novisse, cuius Deus bone non intererit? Circumgerimus ignota miracula & sectamur quisquiliis, extra nos quærentes dum domi peregrinamur.

At obsignata, inquiunt, Mysteria Arti reverentiam, Artifici dignitatem pariunt. Scilicet, is semper mos fuit hominum vel illiteratorum, vel quæstui inhiantium, Religiones Artesq; tanquam scrinio conclusas gerere, ne vel foedæ argui possint inscitæ, vel emolumenti tantillum sibi detrahi sinant: quanquam si legitima virtutis præmia spectent, non aliunde cumulatus nostri ordinis hominibus subministrari sentiant; quam ab ijs, qui vel leuiter initiari vanos etiam metus expavescunt, vel altius instituti fidam Artem vt agnoscunt, ita cum opus est exposcunt & amplectuntur. Sed si neq; veterum calcare viam, nec recentium laudabili instituto insistere velint vt illorum obsequi possint voluntati, quos vel diversa studia vel occupationes a literis alienæ minus idoneos reddiderunt qui rigidam Anatomicorum orationem percipiant; at certe Iuuentuti Chirurgicæ ne inuideant, qui cum de nostra Repub. Colonia sint, æquum est eas leges, ea iura teneant quibus & sibi decori, & nobis, dum res est, vsui esse possint: Qui idcirco non ingenio Stromatico instituendi, aut Cothurnatis Cissionijsq; crepidis induendi, sed per genuina Artis præcepta facili methodo deducendi, vt quæ domi vel suo Marte, tēporum injuria, vix consequi possunt, nostra
opera

opera sibi abunde suppeditata cognoscant, eaq; ita mitigata vt possint concoqui. Neq; enim vbiuis terrarum Doctores Medici ad-sunt, aut Cuiusuis fortunæ est stipendium Medicum numerare; an igitur necessum habeant perire eos omnes quorum vel res angusta vel habitatio a Medicorum frequentia seclusa est?

At saltem secreta Naturæ reuelanda non sunt, neq; auribus oculisue obijcienda quæ male feriatorum mentes & pascant & incendunt. Veniunt hic mihi primo loco repetenda quæ dudum adduxi de consilio omnium Seculorum, Nationum, Hominum, quorum nemo harum partium Historiam detrectauerit; de admiranda Diuini Creatoris in his iisdem partibus sapientia; de Administrationum circa easdem necessitate, quæ eo magis urgere soleat quo symptomata plerumq; inducunt vt grauiora & tristiora ita maxime frequentia. Quid quod Scriptura sacra *Rachaelis* Memes, puerperarum profluvia, Carnis saluationem in Gonorrhœa, semen Concubitus *Sare* *καὶ τὸν ἀνδρὶν ἀποκρίνας* quam admodum violenter, inquit *Stephanus*, seminis Conceptionem pro Emissione interpretantur, describere non erubuit. Attribuendum est aliquid pudicitia. Certe quidem & nos non parum tribuimus, & quoad fieri potuit, re non neglecta quæ sub manibus erat, honestis Circumlocutionibus argumentum molle exasperatum reddimus; vbi proposito insistendum erat, Philosophica (disputatione Lectoris mentem in diuersum trahimus, *Ne vati noceat mala lingua futuro*. Icones non aliæ sunt quam quæ nostro hoc seculo centies impressæ vbiq; terrarum circumferuntur, pijs Principibus & Rebus pub: approbatæ; non aliæ quam quæ virgini castissimæ *Elizabethæ* sacro-sanctæ memoriæ principi Dedicatæ & in manus traditæ sunt.

Deniq; dignitatem mihi exprobant Academicam quod aliorum vestigijs insistens de alieno prodigus de proprio parcus fuerim. Neq; sane diffitebor me sanguinem succumq; hausisse ex alijs; at Methodum, Limina, Limamq; nostra vico, insuper quæ sæpenumero in Disquisitionibus occurrunt partes meas. Addidi etiam plurimorum Anatomicorum *διαχωρίσους*, suffragia, retractationes, demonstrationes *ἐξιδιούσους*: quæ omnia vel colligere, vel collecta repetere vnde desumpta sunt & suis quæq; locis disponere non nudi est Tralatoris; quanquam fuerunt & inter nos sunt viri valde docti quorum diuina longe sequor & vestigia semper adoro, quibus transferendi munus fastido non fuit.

————— *Etiam Parnassia Laurus*

Parua, sub ingenti matris se subijcit Umbra.

Neq; hoc mihi jure quis audaciæ loco imputauerit si remigem prius esse me velim quam ad gubernacula manus admouerim, neq; socordia si proprio utar remigio. Atq; nisi ego fallor, si quis in hoc curriculo mecum desudauerit & pedem pedi contulerit; sentiet profecto se *ἐπὶ ὁλοσθησὶ ἀδὲς σαρδίοσπομῶν*, ita præcipitijs & præruptis anfractibus totus hic ager scatet. Mitto viscerum viam perplexam & spinis obsitam, quæ tot artis proceres collisit: quas va-
forum

forum Conjugationes, quæ diuortia, quam implicitas diuinationes, timari, sequi, & in suos alueos deducere oporteat? Musculorum nomina, originēs, progressus, implantationes; Substructorum ossium appendices, processus, perforationes, suturæ, harmoniæ, gomphoses, diarthroses, synarthroses, enarthroses, arthroidiæ, ginglymoi; eorundem synchondrosis, synsarcosis, syndesmosis, & mille tedia superanda sunt; immensum maris æquor arandum, antequam fugientem oram prehenderis.

Artem tracto tentatam quidem ante me, sed subsultim & leui pede, ab ijs quorum voluntates probaueris potius quam facultates, qui tamen cum primum ad vexillum fuerunt, merito suo Primipili a me audient. In nostro opere fidem inuenies & indefessam diligentiam; orationem, non illam quidem ornatam (qui poteram in abrupta re?) sed evidentem & dilucidam; verborum etiam delectum, sed non tam quæ delectet quam quæ instruat, quamquam & ipsa Artis vocabula adiunximus, sed reddita, vt apud me lector seipsum, apud alios, istos ipsos intelligat.

Atq; hactenus consilij mei rationem, ita vt teneor, exposui, quod vt Majestatis tuæ bona cum venia sit humillime & obnixè contendo. Faucas primitijs crescentis Indolis, quæ si sub tuo Sole adoleuerit & iustam tandem maturitatem consequuta fuerit, non indignos fructus retributuram confido. Interim a Te pro meo opere ^{deus}, pro Te a Deo

Opt. Max. ^{τοῦτο πρὸς τὴν εὐδαιμονίαν} ^{supplex} efflagitabo.

Serenissimæ Majestati tuæ

Subditus Deuotissimus,

HELKIA CROCHYS.

Serenissimæ Majestati tuæ

Subditus Deuotissimus,

HELKIAH CROCVS.

TO THE WORSHIPFULL Company of the Barber-Chyrurgeons, the

Maister, Wardens, Assistants, and Comminalty of the same;

HELKIAH CROOKE, Doctor in Physicke, wisheth

Happie and prosperous Successe in Your

PROFESSION.

Y Maisters and Worshipfull Friends. As from the first I intended this Labor vnto your behoofe; so now hauing by Gods assistance brought it to an end, I offer it vnto you as a token of my Loue: Not that I doubt, but there are some among you who as themselues stand in no neede of my helpe, so they are also able to haue set out this Banquet with greater variety and to haue Cooked it fitter for you as being better acquainted with your diet and appetites. But because it is now a long time since your Banister (that good old man) first presented you with a seruice of this kinde, and no man hath seconded him; I haue aduentured to commit vnto you these my first frutes, which if you shall kindly entertaine and make such vse thereof as I may not thinke my labour misbestowed, you shall encourage me cheerefully to run on that course which I haue propounded to my selfe to further your profiting in that Noble Art which you haue taken vpon you to professe. For when I first began, I intended the Anatomy to be but an entrance into a worke of Chyrurgerie which I had digested into a forme fit, as I thinke, first to ground and establish you in the Principles and Theory or Contemplatiue part of your profession, and after to builde you vp vnto the practise of the same. And because the Body of Man is the Subiect of your Art, without the knowledge whereof it is impossible for a Chirurgeon to worke with any confidence or certainty of successe, I began with Anatomy.

In the next place may in time follow a Discourse of the Constitution of mans body, as he enioyeth a perfect or apportionated health by a due Mixture of the principles whereof he consisteth; of the Temperament of each part arising from that mixture; of the Offices or Functions proceeding from that Temperament, and such other things as will fall in with the same. For as it is a rule in Geometry, that Rectum est index sui & obliqui, That which is Right measureth both it selfe and that which is crooked; so in our Art, he that knowes what should bee the naturall disposition of euerie part will be best able to iudge when Nature declineth from that integrity, and how far the declination is from the true and genuine constitution. This part indeede is Philosophicall, but it may be made so plaine, that a very reasonable capacity shall be able to apprehend it. After you haue knowledge of the healthfull and sound constitution which is the rule of the rest, you must be taught the Natures, Differences, Signes and prognosticks of diseases, so farre as is necessarie a Chyrurgeon should know, that is to say, of Tumours or Apostemations, of Wounds, Vlcers, Luxations, Fractures, and the like. Then followeth

The Preface to the Chirurgians.

loweth the Method of Curing by Indications, which are many and intricate, but yet they may be referred not (without great labour) to outward diseases & illustrated all by examples to make the better impressiō in your minds. In the next place I should come to the operations of Chyrurgery in generall, whereto all the Instruments of your Art doe belong; Engines, Swathes, Ties, Bands and Ligatures, described by Hippocrates, Galen, Oribasius, and those also of the new Chyrurgeons inuentions, with their Figures, interpretations, and manner of application. Afterward the operations in particular, as Division, Simple and Compound; Simple in Section and Vstion; Compound with Extraction and Extirpation. To Junction also Simple and Compound, Simple in Adduction, Adaption and the way how to Containe them so fitted together. Compound with Addition of such decayed Naturall parts as may be restored or imitated by Art. Then comes the cure of Tumors of all kinds both Simple and Compound; of Wounds whether they be made Cæsim or punctim, by Contusion, by Arrowes, Engines or Bullets, with Laceration or without: of the bytings or stinging of venomous Creatures, with their seuerall Antidotes: of burnings, scaldings, and such like.

Next is the doctrine of Vlcers, putride, sordide, fistulated, cancerous, gangrenated, sphacelated and such as are virulent, with the Accidents that vse to accompany them: of Luxations also and Fractures with their kinds and accidents. Afterward of those generall diseases which belong to the whole body, as the Gowt, the Leprosie, the Meazels, the Pox of both kindes, the Plague and such like: and then of the particular diseases from the Head to the Foote, wherein the Chirurgeons helpe is required. Finally, of the Matter of Chyrurgery, that is, of the Nature of those Drugs, Hearbs and Minerals which he hath neede to vse; of their correction and preparation, and of the manner of compounding his Medicines. For I conceiue of the Art of Chyrurgery as of a part of Physick; and therefore of Chyrurgeons as Citizens of the Physitions Common wealth: the difference is, that wee hauing most what better meanes by education to aduantage our wittes, apply them vnto the more abstruse part of the Art separated from the sense and consisting in contemplation and collection; the Chyrurgeon worketh by his eye and with his hand, and dwelleth as it were in the Confinis of that Countrey whose inner part wee inhabit. If therefore they warrant the frontiers and keepe their Stations well and duly therein, may not we better attend to improoue the portion that is allotted vnto vs? But we are both like conetous Farmers, who incroach vppon and get more grounds into their hands then they can well manage, forgetting that wholesome counsell of the wise Poet:

Laudato ingentia rura—Exiguum colito.

Praise a great Farme but occupy a small.

For surely if we aduise well with our selues, Physitians shall find worke enough (though they meddle not with the labour of the hand) to minde the subiect of their Art, I meane Anatomy, wherein too many of vs are wanting to our selues and others; the causes of diseases; the signes of the part affected; the skill of prædiction; the method of curing and the choise of Medicines, with a world of intricate worke beside in apprehending occasions, expecting and imitating the motions and endeavors of Nature, remoouing her obstacles, strengthning her operation and the like. And if we want imployment in those, it seemeth to me more fit to fit our selues thereunto, then casting behind our backs the care of such needfull studies to take vp our precious time in dressing or attending broken heads, strained or luxed ioynts, new wounds or old Vlcers, or in playing the Apothecaries as some doe, who vnder the name of Cordials of x.li. an ounce, Potable Golde, precious

Quin-

The Preface to the Chirurgians.

Quintessences and preparations of Minerals, doe obtrude vpon the worlde either notable impostures or dangerous poysons, ayming indeede at nothing so much (if at any thing else) as at their priuate gaine and the concealing of their ignorance which would neseessarily be detected if they should communicate their practise to Apothecaries as other ingenuons Physitians doe. But of these I haue spoken more largely in an Animaduersion vpon Crollius his Admonitory preface in Latine, and shall haue fitter occasion to speake more elswhere, when I shall be very plaine against those that come in my way.

To retorne whence I haue digressed. Hippocrates the Father and Author of Physicke, the true paterne of ingenuity, put that for one clause in the Oath which himselfe solemnly tooke, and which he would haue all Physitians take, that they should not cut any man for the Stone, but leaue that worke for them that accustome themselues to performe it; as knowing he should finde worke enough to fit his minde for greater difficulties. On the other side the Chyrurgeon should content himselfe with the limits of his profession and not vsurpe vpon the possession of the Physitian, which he doth (sometimes indeede for his profit) but seldome without the detriment of the patient, especially if there be any difficulty in the businesse. I doe not deny, but that a Chyrurgeon, yea a Diuine, or Gentleman, if he lay good foundations and build thereafter vpon them, may be a Physitian as well and as good as the best of vs: but it is not ordinary for men of Manuary Trades or other professions to bee so qualified: the more honour it is for them that bee. But certainly if euery man would containe himselfe within his owne Teather, and presse no further then he is guided by right reason and his reason warranted by experience, we should not heare of so many solæcismes and notable incongruities as are daily committed in our Art.

Neither yet doe I thinke it fit, that the Physitian should be ignorant in the Chirurgical part, but able to guide the Chyrurgeon that is not able to guide himselfe, to assise and confirme him that is, and to amend a fault when it is committed: but for the worke of the hand, I take it to be more lawfull for him then expedient, more honourable to bee able and not to doe it, then profitable to do it though he bee neuer so well able. Albeit to say the truth, the fault is more common on the Chyrurgeons part then on the Physitians; and by so much the greater, by how much the danger of not doing well is more in very many, then the disreputation or disadvantage can be to a few (and very few they be indeede of the better sort) who do all they can.

Notwithstanding, because some men are importunately bolde aboue their skill, shall it not be thought fit that all may learne that they ought to haue skill in, and is an essentiall part of their profession? Let them then learne it (saith the Physitian) as wee doe. As much as if he should say to his patient that is not able to helpe himselfe: There is an excellent Medicine for your malady in Galen, I pray you seeke it out. It is indeede a disease in our common-wealth, that Chyrurgeons haue no better meanes to instruct themselues; If therefore (you will say) they meddle so much now, what will they not undertake when they are better provided? Surely not so much: for who are those that busy themselues most in the matter of physicke, but such as are least able? The able and discreete Chyrurgeon when hee hath learned anie thing hath also learned the difficulty of physicke, and will bee readier to pray in aide of the learned Physitian, then hee that runs boldly headlong without foresight of danger.

Seeing therefore it is necessary Chyrurgeons should be instructed for the behoofe of the Common-wealth, whose generall good is to be preferred before all particulars; why

The Praeface to the Chirurgians.

Should we not bee rather willing to instruct them our selues when wee may holde them within the compasse of their owne Art, then driue them to seeke other helpes to our preiudice? Now then, among all the parts of our Art there is none that the Chyrurgeon hath more neede of, or that is of more vse for himselfe then Anatomy, none that doth lesse inable him to practise physicke, it being a mere Naturall study, teaching him where to seeke the Veine he must open; how the ioynt should bee reposed which he findeth luxed; what parts are neare the wound which he searcheth, and therefore may be offended with it; which way the Fibres, Vessels and Tendons run, that in his incisions he may not violate them; how to cast on his Bands to containe a Fracture or Luxation; how to auoide the most sensible and vsesfull parts in Trepaning, Cauterizing, dismembring and such like: but of medicine and the cure of inward diseases in Anatomy not a word. The inward parts are also indeed Historified, whose position at least (you will grant vnasked) it is fit the Chyrurgeon should know; else when we appoint a plaister to the Liuer hee may lay it to the left side, when for the Spleen on the right. But he may be directed. That is not perpetuall; Physitians are not in all places, nor all men fit to entertaine them when they are to be had. Beside, a Chyrurgeon should not alwaies be an apprentice, but at length a Maister of his Art, fit to instruct others, not alwaies standing in neede of instruction himselfe, vnlesse it be in difficulties, when I know no Physitian but will bee glad of assistance. Add hereto, that all Physitians, in all ages, kingdoms and free states, haue written their Anatomy and Art of Chyrurgery in their mother-tongues, or afterward translated them for the vse of Chyrurgeons; which is so well knowne that it were in vaine to make repetition of particulars. To come to our selues; we finde many examples of learned men and good Patriots, who haue bene willing to take great paines and to be at great charge for this purpose.

Against the rest D. Cawdwell sometimes President of the Colledge of the Physitians in London, first translated Moores Tables, and (a learned man though hee were) was not ashamed to do that seruice to his country as to make himselfe, as some vnworthily and scornfully terme it, A bridge for asses to passe ouer by. Hee also promised Oribasius de Laqueis, which his labor seemeth to haue bene interrupted by his death or otherwise lost, to the great detriment of Chyrurgery. But for Anatomy hee did not onely take paines in it, but was also at great cost to cut the figures in Brasse, which he left remaining in your hands (my Maisters of Chyrurgery) as a testimony of his great desire to further your profiting in that part. Moreouer that honorable person the Lord Lumley erected a Chyrurgery Lector in the Colledge of Physitians, allowing liberall maintenance to a Doctor of Physick to reade the same twice a week, partly in Latin, and partly also in English for the vse of the Chyrurgeons, and to goe ouer the whole body of Anatomy euery yeare a part; which Lecture is not so duly followed and frequented, as it is performed at this time by D. Dauies, of whom I cannot but make worthy mention hauing receined not onely great contentment but profit also by his learned readings. You haue also among you a laudable custome to procure a Doctor of Physick to reade vnto you, and to provide that his Lectures be duly attended by those of your society: and the Physitians, I doubt not, thinke they haue done well in singling out a learned man to instruct you. Onely your care must be, to feed vpon that rather which is *idvqua*, then vpon that which is *idvqua*, vpon that which is good for nourishment rather then vpon that which will delight and fill but not feede your minds: to attend the plaine-song rather, then the diuision or descant, which doth oftentimes corrupt the Musick if the auditors

The Preface to the Chirurgians.

care be not carefull to distinguish them. Finally, you haue Anatomies both priuate for your profitting and publike for the honour and reputation of your Company read in your Mother tongue. And truly me thought it did me good to see so graue a company of gowned Chyrurgeons attending vpon it, so good order, so great a Crowne of worthy Auditors, so liberal entertainment at it: which I do not mention to flatter you, for flattery is to attribute more then desert, but partly to commend your praise worthy care; partly if it were possible to stir vp our selues to a lawfull emulation.

To returne. These many paternes, these worthy presidents first warranted me, after perswaded me to spend those houres which I might spare from my employments in these and the like labors. For which as I esteeme my owne profitting to bee a sufficient and answerable reward, so I did and do hope that my paines being communicated to others would returne vpon me with aduantage; that aduantage I meane, which is most welcome to honest minds, that is, a conscience of hauing improued though but a single talent. It were in vaine to Apologize for my selfe that I haue not had that time, those opportunities, those meanes which are required to an exquisit Anatomist, because (it may bee answered) I might then haue held my hand and giuen way vnto such as had them. There is indeed a time when a man should stand much vpon the consideration of his strength. There is also a time wherein it is lesse dishonor to want power then will, ability then good endeavour. He that first scales the battlements of a Castle or Citadell though his body bee not sufficient to oppose against a whole Squadron, yet if hee win the wall and make way for the victor, deserues a Murall Crowne. Whilst other men (put case) more able, haue looked on and pittied themselues, I haue giuen the onset, with courage enough if not too much, & viui peruenimus; but with what dextery is in you to iudge. Many obiections are made against me. First, that being a professed Scholler I should haue written in Latine. That indeed had bene easier for me by far, hauing the words made to my hands, the passages chalked out, and plenty of Authors to haue gleaned from, and a little Latine, such as it is to haue varied my discourse: but it had bin most ydle, my purpose being to better them who do not so well vnderstand that language. I should, saide another, haue made an Anatomy of my owne. Such Guls little know what it is to write an Anatomy; thirtie yea forty yeares practise (which are more then the daies of my life) in dissection, and a hundred bodies more or lesse, small and great euery yeare, hath bin thought little enough to make an Anatomist fit to teach this learned age; for which I dare bouldly say, no man amongst vs that knowes himselfe can esteeme himselfe sufficient, because wee want those meanes which other Countries afford their professors. Notwithstanding my counsell and end of right I require should be approued, my performance not so. The figures are no other then those of Vessalius, Plantinus, Platerus, Laurentius, Valuerdus, Bauhinus, and the rest; no other then those which were among our selues dedicated to three famous Princes, the last a Mayden-Queene. For my adding the History of the parts of Generation, I haue already giuen account, partly to his Maiesty, partly in my Prefaces to the fourth and fift bookes. My present worke is for the most part out of Bauhine for the History, Figures, and seuerall Authors quoted in his Margents. The Controuersies are most what out of Laurentius, with some additions, substractions and alterations as I thought fit and my wit would serue. The Method I haue altered throughout, transported the Tables as seemed best vnto me, reuised and made choise of the quotations in Bauhine, and interposed them in their owne places. I also added Prefaces to euery booke containing the argument and purport thereof: and in the subsequent discourse

The Praeface to the Chirurgians.

many passages partly out of my owne observations, partly as I met with them in approved Authors. The streame and current of Bauhines discourse because it is very hard, intricate, and full of long continued sentences, I haue broken off and parted as it might best be vnderstood, which was one thing that made the volume to swell. The words of Art most what I haue kept that you might not be vnacquainted with them, yet haue I also rendred them as well as I could into our language.

The first booke is almost wholly out of Laurentius sauing for some passages, so is the fift, and had not the bulke of the volume growne too great, and so too chargeable to the Printer, I intended beside these thirteene Bookes some other observations; the grounds whereof I had from that excellent and oculate Anatomist Petrus Pauus of Leyden, my Maister and moderator in Anatomy. Heere you haue the worke perfected; not onely as Bauhine hath it in three Venteres and the Ioynts, but also after those, the kinds of Flesh, Simple, musculous, with the exact story of the Muscles throughout the whole body, the flesh of the Bowels and the Glandules. In the next place, the Vessels, Veines, Arteries and sinewes, with their diuarcations and diuisions from their originals euen to the extreme parts. Then the Membranes, Ligaments, Gristles and Fibres. And lastly, that cragged and rockie treatise of the Bones. In all which I haue added the Natures and Definitions of euery particular and the explications of them: their differences and diuisions with their Vses and actions; all which are omitted by Bauhine in his Theater, but supplied by me, partly out of Laurentius, partly out of those Dictates I gathered from Petrus Pauus before named. Finally, betwixt the 7. booke which contained the history of the vpper Venter, that is, the Head, and the ninth of the Ioyntes, I haue interposed a Booke of the Senses, collected out of Bauhine, Laurentius, and Iulius Casserius Placentinus, who wrote very accurately of that subiect, many of whose disputations I haue also added. One thing I craue pardon for aboue all the rest, and that is Casserius his praeface before the Controuersies of the eight booke, which indeede was not done by me, and the matter it selfe, to say truth, I doe not so well like. Againe, although I reuised the Presse, or rather the sheets and proofes, as they call them, my selfe; yet being sometimes out of Towne about my practise, and often though in towne yet necessarily called away from attending the correction, many litterall faults haue escaped, especially in the Greeke, and some more then literall, yet few such as well stumble the Reader, and fewer, it will be, then could be imagined should escape a worke of such vncouth argument to the Compositors, and written besides in a Schollers running hand. Thus much I thought good to aduise you of, my kinde and Worshipfull Friends, and so to commend my labor to your good acceptance and your honest endeavors and studies in this and other parts of your Art to Gods blessing.

From my house in S. Annes Lane, this last of May, 1615.
By your Louing Friend HELKIAH CROOKE.

TO THE YOUNGER SORT of the Barber-CHIRVRGIANS.

Y Friends, The Printer hauing made his voyage and returne of the first Impression of the Anatomy, solicited me againe to reuise the Coppie for a second Edition, which I haue now finished as you see with paines and care that what escaped before might bee now amended. I confesse I hoped well at first that my labour would be acceptable vnto you, and I confesse as freely that my hope hath not beene frustrate: I haue therefore my reward, and that reward hath encouraged me to step one step farther for your behoofe, that is, to explicate the vse of some Chirurgicall Instruments which are vsfull in your Art. Not with intention to write a *practise of Chirurgery* (as the Printer in my absence this Summer hath vnadvisedly of his owne head entituled it) but onely that by this manuduction, you might bee led, to teach you to goe by your selues afterward. Beside, it is but a little that is done, and will serue to whet the appetite rather then to satisfie it: Neither indeede could it be much, partly because I had not much time to spare, or if I had, would the volume haue borne much more. *Pareus* pleased me best, as being not onely in my account but in common esteeme the best Chirurgian. The Instruments therefore are all his, and so is most of the discourse vpon them, sauing that now and then you shall finde his prolixitie contracted, his obscurity explained, and here and there a few things added. His Medicines I purposely set downe in Latine to acquaint you so to vnderstand them. Thus much shall suffice by way of advertisement: Fare you well.

From my Study in Colemanstreete
Octob. 30. 1630.

TO THE YOUNG SORT

I have been thinking of you very much lately, and wondering how you are getting on. I hope you are well and happy. I have been very busy lately, but I have managed to find some time to write to you. I have been thinking of you very much lately, and wondering how you are getting on. I hope you are well and happy. I have been very busy lately, but I have managed to find some time to write to you.

Yours truly,
John Smith

The Contents of the feuerall Bookes
contained in this Volume.

I. Booke.

Of the Excellency of Man, together with the Profite, Necessity, Antiquity and Method of Anatomy.

II. Booke.

Of the parts Inuesting and Conteyning the whole Bodie, and also the Lower Belly in particular.

III. Booke.

Of the parts belonging vnto Nutrition and nourishment.

IIII Booke.

Of the naturall parts belonging to Generation.

V. Booke.

Of the History of the Infant, most accurately described, according to the opinion of *Hippocrates*.

VI. Booke.

Of the Middle Region, called the Chest, containing the vitall parts.

VII. Booke.

Of the third & vppermost *Venter*, called the Head, wherein are described the Animall organs.

VIII. Booke.

Of the Senses and their Instruments, and also of the voyce.

XI. Booke.

A brieife description of all the Ioynts.

X. Booke.

Of Flesh, that is, of the Muscles, the Bowels, and the Glandules.

XI. Booke.

Of the vessels containing three parts, namely, Veines, Arteries, and Sinewes.

XII. Booke.

Containing foure parts, viz. Gristles, Ligaments, Membranes, and Fibres.

XIII. Booke

Of the Bones.

The Contents of the Jewell Booke

Containing the Jewell Booke

I. Booke. Of the excellency of Man, and
of the worth of the Jewell Booke,
And the nature and use of it.

II. Booke. Of the four parts of Man, and
of the nature of the Jewell Booke, and
of the use of it.

III. Booke. Of the nature of the Jewell Booke,
and of the use of it.

IV. Booke. Of the nature of the Jewell Booke,
and of the use of it.

V. Booke. Of the nature of the Jewell Booke,
and of the use of it.

VI. Booke. Of the nature of the Jewell Booke,
and of the use of it.

VII. Booke. Of the nature of the Jewell Booke,
and of the use of it.

VIII. Booke. Of the nature of the Jewell Booke,
and of the use of it.

IX. Booke. Of the nature of the Jewell Booke,
and of the use of it.

X. Booke. Of the nature of the Jewell Booke,
and of the use of it.

XI. Booke. Of the nature of the Jewell Booke,
and of the use of it.

XII. Booke. Of the nature of the Jewell Booke,
and of the use of it.

XIII. Booke. Of the nature of the Jewell Booke,
and of the use of it.

XIV. Booke. Of the nature of the Jewell Booke,
and of the use of it.

XV. Booke. Of the nature of the Jewell Booke,
and of the use of it.

The Table of the feuerall Chapters and Questions contayned in this whole Volume.

The first Booke.

CHAP. I.

THE Excellency of Man is declared by his parts, uamely the Minde and the Body, and first what is the dignity of the Soule. Folio 3

Chap. 2. Of the wonderfull frame of Mans body. Folio 4

Chapter 3. *Epicurus, Momus, Pliny* and other the malicious and false detractors from Nature are censured, &c. 8

Chap. 4. Wherein the body of Man differeth from that of other creatures, &c. 10

Chap. 5. How profitable Anatomy is vnto euery mans selfe. 12

Chap. 6. How profitable Anatomy is to the knowledge of God. 14

Chap. 7. How profitable Anatomy is to Philosophers, Artificers, and Handy-crafts-men. 15

Chap. 8. The necessity of Anatomy for Physitians and Chyrurgions. 16

Chap. 9. With what method Anatomy may be best demonstrated. 17

Chap. 10. Who haue written of Anatomy. 20

Chap. 11. What *Galen* hath written of Anatomy, and how he was vniuſly accused by *Vesalius*. 22

Chap. 12. How far *Aristotles* skill stretched in Anatomy. 24

Chap. 13. What other Greeke Authors haue written of Anatomy. Ibid.

Chap. 14. Who haue beene the chiefe Authors of Anatomy in our times. 25

Chap. 15. The instruments necessary to Anatomy 26

Chap. 16. What is the subiect or immediate object of Anatomy. 27

Chap. 17. What an Anatomist must consider in euery part. 28

Chap. 18. The differences of parts, &c. 30

Chap. 19. A diuision of parts, &c. 31

Chap. 20. An elegant diuision of parts into similar & dissimilar, &c. 32

Chap. 21. The other differences of the parts vnfolded. 34

The Controuerſies of the first Booke.

QUEST. I.

THe definition of a part. Folio 38

Quest. 2. The principality of the parts against the *Peripateticks*. 39

Qu. 3. How many principall parts there are. 43

Qu. 4. Of the nobleſt principall part. 45

Qu. 5. Of Similar and Dissimilar parts. 47

Qu. 6. Whether a Similar part may be called Organicall. 48

Qu. 7. Whether the Spermatieall parts be generated of Seede. 50

Qu. 8. Whether the Spermatieall parts can reioyne againe after they be violated and ſenered or broken. 54

Qu. 9. Whether the spermatieall parts be hotter then the flesh. 57

Qu. 10. Whether the ſolid parts become dried can be made moiſt againe. 59

The ſecond Booke.

CHAP. I.

THe diuision of the body of man. Folio 63

Chap. 2. The diuision of the lower belly. 65

Chap. 3. Of the composition or frame of the lower belly. 66

Chap. 4. Of the haire of the whole body. 67

Chap. 5. Of the cuticle or ſcarfe-skin. 70

Chap. 6. Of the Skinne. 72

Chap. 7. Of the Fat. 74

Chap. 8. Of the fleshy membrane. 77

Chap. 9. Of the inueſting or containing parts proper to the lower belly. Ibid.

Chap. 10. Of the *Peritonæum* or rim of the belly. 78

Chap. 11. Of the vmbilicall or Nauell veſſels. 81

The Controuerſies of the ſecond Booke.

QUEST. I.

How the haire are nourished. Folio 84

Quest. 2. Whether the skin be the organ of touching. 85
3 Of

The Table.

3, Of the temper of the Skin.	87
4, Whether the skin performe any common and officiall action.	88
5, Whether it be heat or cold whereby fat is congealed.	Ibid.
6, Whether fat be a living and animated part of the body.	89
7, Of the membranes, vse and production of the Peritoneum.	92
8, A new kinde of compunction of dropisie bodies through the Nauell.	93

The third Booke.

CHAP. I.

O F the Naturall parts contained in the lower belly.	97
2, Of the <i>Omentum</i> or kall.	98
3, A briefe description of the Gate veine and his branches.	101
4, The arteries of the stomacke and the mesentery, which accompany the branches of the Gate-veine.	103
5, Of the Guts.	105
6, Of the Mesentery.	111
7, Of the <i>Pancreas</i> or sweet-bread,	113
8, The branches of the Hollow veines and great artery.	114
9, Of the stomacke.	116
10, Of the <i>oesophagus</i> or gullet.	122
11, Of the Spleene or milt.	124
12, Of the Liuer.	129
13, Of the bladder of gall.	135
14, Of the Kidneyes.	139
15, Of the <i>ureters</i> or passages of vrine.	149
16, Of the Bladder.	150
17, Of the Fundament.	154
18, The muscles and nerues situated in the lower belly.	Ibid.
19, The bones of the lower belly.	155
20, Of the breasts or paps.	156

The Controuersies of the third Booke.

CHAP. I.

V Whether the Guts haue any common attractive faculty.	161
2, Whether the guts haue any common retentive faculty.	163
3, Whether the guts haue any concocting faculty.	164
4, Of the expulsive vertue of the guts,	165
5, Whether Clusters can passe vpward vnto the Stomacke. Folio	166
6, Of the euill fauour of the excrements.	167
7, Of the substance and scite of the Guts.	168
8, Whether the vpper mouth of the stomacke bee the seate of Appetite.	169
9, The situation of the vpper mouth of the stomacke, Folio	170
10, Whether the <i>Chylus</i> bee made by heat or by the forme of the stomacke.	Ibid.
11, Whether the stomacke be nourished by the <i>Chylus</i> or by blood,	171

12, What is the nature of a spirit, &c.	171
13, Whether the bladder doe draw the Choller vnto it for nourishment.	176
14, The passages by which the Choller is purged, against <i>Falopius</i> .	178
15, The vse of the Spleene against the flauenderous calumniations of <i>Galenus</i> aduersaries.	181
16, How the melancholy iuyce passeth from the spleene to the bottom of the stomacke.	185
17, How those that are spleeniticke are purged by vrine, &c.	186
18, Vse of the Kidneyes, and matter of the vrine.	187
19, That the reasons of diuers Symptomes which follow such as are afflicted with the stone are to be required from Anatomy,	189
20, Whether the bladder do draw the vrine,	191
21, Of the Retention and Excretion of the vrine, &c. Folio	192
22, Of the action and vse of the Paps.	Ibid.
23, Whether milke can be generated before Conception. Folio	193
24, Certaine Problemes vnfolded concerning the generation of milke,	195

The fourth Booke.

CHAP. I.

O F the necessity of the parts of Generation, Folio.	199
2, Of the preparing spermatike or seede vessels.	200
3, Of the <i>Parastata</i> .	202
4, Of the Testicles.	204
5, Of the vessels called <i>vasa deferentia</i> , or leading vessels.	207
6, Of the bladders of seed.	208
7, Of the <i>Prostata</i> .	209
7, Of the virile member.	210
9, Of the proportion of these parts both in men and women.	216
10, Of the preparing spermatikall vessels in women.	217
11, Of the Testicles.	218
12, Of the <i>vasa deferentia</i> or leading vessels,	220
13, Of the wombe or matrix.	221
14, Of the simple or similar parts of the wombe, and particularly of the bottom and orifice.	222
15, Of the necke of the wombe and of the <i>Hymen</i> . Folio	234
16, Of the Priuities.	237
17, Of the wombe of a sheepe and a dog.	239

The Controuersies of the fourth Booke.

QVÆST. I.

V Whether the Testicles be principall parts or no.	241
2, Of the vse of the Testicles.	243
3, The	

The Table.

- 3, The opinion of Physitians concerning the true vse of the Testicles. 245
- 4, Of the substance and coates of the Testicles. 246
- 5, The consuetude between the chest and the Testicles. Ibid
- 6, The situation of the Prostate. 247
- 7, Whether the erection of the yard, be a Naturall or Animall action. Ibid
- 8, How the parts of generation in men and women doe differ. 249
- 9, The motions of the wombe. 250
- 10, How the wombe is affected with smells and with saours. 251
- 11, The wonderfull consent between the wombe, and almost all the parts of womens bodies. 252
- 12, Concerning the *Acetabula*, the hornes and coates of the wombe. 255
- 13, The membrane called *Hymen* and the markes of virginity. 256

The fifth Booke.

C A A P. I.

- W**Hat things are necessary toward a perfect generation. 258
- 2, The principles of generation, seede, and the mothers blood. Ibid.
 - 3, The mothers blood the other principle of generation. 260
 - 4, Of Conception. 262
 - 5, The conformation of the parts. 263
 - 6, The nourishment of the Infant, and how it exerciseth the naturall faculties. 266
 - 7, How the infant exerciseth his vitall faculties, folio 267
 - 8, The motion and situation of the Infant in the wombe which are animall faculties. 268
 - 9, The exclusion or birth of the child. Ibid.

The Controuersies of the fifth Booke.

Q V E S T. I.

- O**F the differences of the sexes. 270
- 2, Of the temperament of women, whether they are colder or hotter then men. 272
 - 3, What Seed is. 277
 - 4, Whether Seed fall from all the parts of the body. 279
 - 5, Whether women yeeld seede. 283
 - 6, The excretion of the seed, by what power or faculty it is accomplished. 286
 - 7, Whence cometh the pleasure in the eiaculation of seede. 287
 - 8, Whether the Menstruall blood haue any noxious or hurtfull quality therein. 288
 - 9, Whether the menstruall blood be cause of the meazels and small pox, which are wont once in a mans life to trouble him. 290
 - 10, The causes of the periodical euacuation of the menstrua. 294
 - 11, Whether it be necessary to Conception that the

- Seed of both Sexes should issue together, and that with pleasure, and be presently mingled. 294
- 12, Whether the wombe haue any operative or actiue power in the conformation of the Creature. 296
 - 13, The vicious or faulty Conceptions, and especially of the Mola. 297
 - 14, Of Monsters and Hermaphrodites. 299
 - 15, Whether al the parts are framed together. 300
 - 16, Whether the membranes which encompasse the Infant be first formed, and whether they bee made by the forming faculty and seed of the woman. 304
 - 17, The number of the vmbilicall vessels. 305
 - 18, The originall of the vmbilicall vessels. 306
 - 19, The times of the conformation of a man and of a woman childe. 307
 - 20, Whence it cometh that children are like their Parents. 308
 - 21, How Twinnes or more Infants are generated. 312
 - 22, How superfetation is made: why onely a woman when she hath conceived, desireth the company of the male. Folio, 313
 - 23, Whether the Infant draweth his nourishment at his mouth. 315
 - 24, Whether the Infant be nourished onely with blood, and whether he accomplish only one concoction. Folio, 316
 - 25, Of the communion of the foure vessels of the heart in the Infant, demonstrated in three Exercises. 317
 - 26, Whether the Infant in the wombe doe respire, and stand in need of the labour of his Lungs. 326
 - 27, Whether the vitall faculty which procreateth the spirits is idle in the Infant, and whether his heart is moued by his owne proper power, a paradox. 327
 - 28, Whether there be in the Infant any generation of animall spirits, and what position the Infant hath in the wombe. 331
 - 29, Of the nature and differences of the birth. 332
 - 30, How many times there be of a mans birth, and what they are. 334
 - 31, What are the vniuersal and particular causes of the birth. 338
 - 32, Whether in a desperate birth the Casarian Section be to be attempted. 343
 - 33, Whether in the birth the share and the hanch bones depart asunder. 344

The sixth Booke.

- O**F the *Thorax* or Chest, and the diuision of it. Folio 347
- 2, The Skinne and Fat of the Chest and the necke. 348
 - 3, The muscles of the middle belly, and parts of the necke. 349
 - 4, Of the muscles between the ribs, called *Intercostales*. 350
- † 2
- 3, Of

The Table.

5, Of the midriffe called <i>diaphragma</i> .	352
6, Of the membrane called <i>pleura</i> .	355
7, Of the <i>Mediastinum</i> .	356
8, Of the <i>Thymus</i> and purse of the heart.	358
9, The ascending trunk of the hollow veine.	361
10, Of the nerues in the Chest and necke.	365
11, Of the Heart.	367
12, Of the substance, ventricles and eares of the heart.	371
13, Of the vessels of the heart and their values.	374
14, Of the great artery and his values.	379
15, Of the vnion of the vessels of the heart in the Infant vuborne.	Ibid
16, Of the great artery in the Chest and in the necke.	382
17, Of the Lungs.	384
18, Of the weazon or winde-pipe.	388
19, The muscles and nerues in the cavity of the Chest.	391
20, Of the clauicles, brest bone and Ribs.	392
21, The bones of the chest.	394
22, Of the shoulder blade & racks of the neck.	396

The Controuersies of the first Booke.

QUEST. I.

A N Anatomical demonstration concerning the phrensie of the Midriffe.	399
2, Of the motion of the heart and Arteries.	400
3, Of the manner of the motion of the heart.	403
4, By what power the arteries are moued.	405
5, VVhether the arteries be dilated with the heart.	407
6, Of the generation of the vitall spirits.	410
7, How the matter of the <i>Empyici</i> is purged.	414
8, The Temperament, Nourishment and Flesh of the heart.	417
9, VVhether the heart will beare any grievous disease.	419
10, Of the nature of Respiration and the causes thereof.	420
11, Of the temperament and motion of the Lungs.	423
12, Of the Cough and the drinke falling into the lungs.	426

The seuenth Booke.

CHAP. I.

O F the names, situation, forme and parts of the head.	432
2, Of the common cõtaining parts of the head.	434
3, Of the muscles about the head.	436
4, Of the figure and sutures of the head.	437
5, Of the bones proper to the scull.	441
6, Of the bones common to the scull and the vpper law.	442
7, Of the <i>Meninges</i> or membranes of the head.	443
8, The vessels disseminated through the braine.	450
9, The excellency, situation, figure, substance, and temperament of the braine.	452
10, Of the substance and parts of the braine.	455
11, The ventricles of the braine, the Arch, and the <i>Plexus Choroïdes</i> .	460
12, Of the resemblances in the braine, & the fourth	

ventricle.	466
13, Of the vse of the braine.	469
14, Of the <i>Cerebellum</i> or After braine.	475
15, Of the spinall marrow or pith of the backe.	479
16, Of the organs of smelling.	483
17, Of the opticke nerues.	485
18, Of the third and fourth Coniugations of the nerues of the braine.	486
19, Of the nerue of hearing, &c.	487
20, The sixt seueneth and eight coniugation of the sinewes.	Ibid
21, Of the nerues of the spinall marrow.	488
22, <i>Varolius</i> his manner of dissection the head.	493

The Controuersies of the seuenth Booke.

QUEST. I.

V Vhether the Braine be the seate of the principall faculties	502
2, Of the marrow of the backe.	504
3, Whereupon the principall faculties depend.	506
4, The vse of the Braine against Aristotle.	507
5, Why the contrary side of the wounded head suffers convulsion.	509
6, Why the part opposite to the wounded is resolved.	512
7, The nature, generation, and place of the animall spirit.	514
8, <i>Argenterius</i> his conceit of the animall spirit disproued.	516
9, How the braine is moued.	519
10, Whether the braine hath any sense.	522
11, The temperament of the braine.	524
12, The manner and wayes of the braines excrements. Fol.	525
13, The number and vse of the ventricles.	528
14, Which of the ventricles are most excellent. Ib.	

The Eight Booke.

CHAP. I.

O F the Face his vessels and muscles.	532
2, Of the Eye and parts thereof.	535
3, Of the Eye browes and eye lids.	540
4, Of the fat and muscles of the eies.	547
5, Of the vessels of the eyes.	551
6, Of the membranes of the eyes.	553
7, Of the grapy membrane.	559
8, Of the Cobweb, &c.	564
9, The humors of the eyes.	565
10, The vse of the humors of the eye.	568
11, Of the outward eares.	573
12, The parts of the outward eare.	578
13, The muscles of the outward eares.	580
14, The gristle of the eare.	581
15, Of the inward eare.	582
16, The canale out of the eare into the mouth.	586
17, The membrane of the Tympane or drum.	588
18, The small bones of the chord.	593
19, The muscles of the inward eare.	597
20, The canities of the stony bone.	601
21, Of the windowes and watercourse in the first cavity.	602
22, Of	

The Table.

22, Of the Labyrinth and Cochlea.	603	34, That the pure elements are not coloured of themselves.	686
23, The nerve which ariseth at the eares.	605	35, Of the generation of colours & of their forme.	687
24, Of the implanted or inbred ayre.	606	36, Of the <i>Medium</i> or meane of the sight.	689
25, The manner of hearing & nature of sounds.	609	37, Whether light be the forme of that which is perspicuous.	690
26, Of the Nose.	613	38, Of the production of a sound.	691
27, Of the coate and vse of the nose.	614	39, The definition of a sound.	693
28, Of the inner nose and manner of smelling.	616	40, Of the differences of sounds.	694
29, The lower parts of the Face.	620	41, Of the manner of hearing.	695
30, Of the mouth, palat and <i>uvula</i> .	621	42, What is the principall organ of Hearing.	696
31, Of the Fauces, or Chops and Almonds.	624	43, An explication of certaine hard Problemes about the eares.	697
32, Of the tongue and his muscles.	626	44, Of the wonderfull sympathy and consent of the eares, the palat, the tongue, and the throttle.	700
33, Of the sense of tasting.	631	45, What smelling is.	702
34, The <i>Larynx</i> or throttle.	633	46, Why man doth not smell so wel as many other creatures.	702
35, Of the <i>Glottis</i> and cleft of the <i>Larynx</i> .	639	47, Of the essence of an odour.	703
36, Of the <i>Epiglottis</i> and his muscles.	641	48, The definition of an odour.	706
37, Of the membrane of the <i>Larynx</i> .	643	49, Of the causes of odours.	707
38, Of the found and the voyce.	640	50, Concluding that Fishes doe not smell.	708

The Controuersies of the eight Booke.

CHAP. I.

V What Sense is.	652	51, Of the differences of odours.	709
2, What Action is.	Ibid.	52, Of the <i>Medium</i> or meane of smelling.	710
3, The end of action.	654	53, After what manner an odour affecteth or changeth the medium.	711
4, How manifold Action is.	Ibid.	54, What is the true organ of smelling.	712
5, That sense is not a pure passion.	656	55, Whether taste be the chiefe action of the tongue.	714
6, That Sense is not a simple action.	657	56, Whether the taste differ from the touch.	714
7, <i>Placentinus</i> his opinion.	Ibid.	57, Of the object of tasting.	715
8, How the faculty is wrought in the Sense.	658	58, Of the matter of sapor.	718
9, Where Sensation is perfectest.	659	59, Of the efficient cause of sapor.	719
10, That by our outward Senses we doe not know that we haue sense.	Ibid.	60, Of the number of sapor.	Ibid.
11, Whence it is that we perceine that we haue sense.	660	61, Of the medium or meane of tasting.	727
12, Of the number of the Senses.	Ibid.	62, Of the organ of tasting.	722
13, Of the order of Senses.	661	63, Whether the tongue alone doe taste.	724
14, A confirmation of the order of Senses.	Ibid.	64, In what part of the tongue the taste is most exact.	Folio 725
15, The arguments of the Philosophers.	662		
16, The arguments of the Physitians.	Ibid.		
17, The Authors owne opinion.	663		
18, Whether the Senses doe neede a medium or meane.	Ibid.		
19, What the medium ought to be.	664		
20, What an object is.	665		
21, Of the organs of the Senses.	666		
22, Of the manner of seeing.	Ibid.		
23, Whether we see that which is within the eye.	670		
24, Whether the organ of sight be fiery or watery.	671		
25, Wherefore the eyes be diuersly coloured.	673		
26, Of the muscles of the eyes & their motion.	675		
27, Two obscure & intricate questions concerning the motion of the eyes are resolved.	Ibid.		
28, Of the humors of the eyes, whether they be animated parts.	677		
29, Of the originall of the opticks, their meeting and insertion.	678		
30, Whether the light be the object of the sight.	680		
31, Of the nature of light and what it is.	681		
32, Of the differences betwixt <i>Lux</i> or light it selfe, and <i>Lumen</i> or illumination.	683		
33, That colour is the object of sight.	684		
34, Whether colour be light.	685		

The ninth Booke.

CHAP. I.

A Briefe description of the Loynes.	728
2, Of the parts of the Loynes in generall.	Ibid.
3, Of the excellency of the hands.	729
4, Of the vse, figure, and structure of the hand, properly so called.	730
5, Wherein is declared the reasons of the framing of all the similar parts, whereof the hand is compounded.	732
6, Of the distincter parts of the hand, of the wrest, and of the afterwrest.	732
7, Of the fingers of the hand.	Ibid.
8, Of the Foote in generall, his excellency, figure, structure and vse.	733
9, The similar parts of the Foote in the large acceptation.	734
20, An explication of the dissimilar parts of the whole foote.	735

The

The Table.

The tenth Booke.

CHAP. I.

V What flesh is, and how many sorts of flesh there be.	737
2, Of the flesh of the muscles, and what a muscle is.	738
3, How many and what be the parts of a muscle.	739
4, What is the action of a muscle, and the differences of the motion thereof.	741
5, Wherein all the differences of muscles are shovne.	742
6, Of the number of the muscles.	743
7, Of the muscles which moue the skinne of the head.	745
8, Of the muscles of the eye lids.	746
9, Of the muscles of the eye,	847
10, Of the muscles of the outward eare.	750
11, Of the muscles within the eares.	752
12, Of the muscles of the nose.	753
13, Of the common muscles of the Cheekes and Lips.	754
14, Of the proper muscles of the Lips.	755
15, Of the muscles of the lower law,	757
16, Of the muscles of the chops which serue for deglutition or swallowing.	760
17, Of the muscles of the bone called <i>Hyois</i> .	1b.
18, Of the muscles of the tongue.	761
19, Of the muscles of the <i>Larynx</i> .	763
20, Of the muscles of the <i>Epiglottis</i> or of the ouer-tongue.	766
21, Of the muscles which moue the head.	767
22, The muscles of the necke.	771
23, The muscles of the shoulder-blade called <i>Omo-plata</i> or <i>Scapula</i> .	772
24, Of the muscles of the arme.	775
25, Of the muscles of the Cubit.	780
26, The muscles of the <i>Radius</i> or wand.	782
27, Of the muscles of the hand in generall.	785
28, The muscles of the palme, and two or three o-ther issuing from the fleshy membrane.	786
29, The substance which commeth between the skin of the palme, and of the fingers and their ten-dons.	1b.
30, The muscles which bend and extend the fore-fingers.	787
31, Of the muscles that bend and extend the thumb.	789
Folio	789
32, Of the muscles of the afterwrest and the wrest.	791
Folio	791
33, The muscles of Respiration.	793
34, Of the muscles of the <i>Abdomen</i> or panch.	796
35, The muscles of the backe.	801
36, The muscles of the fundament, the bladder, the testicles, and the yard.	803
37, The muscles of the Leg.	804
38, The muscles of the thigh.	807
39, The muscles of the foote.	813
40, The muscles of the Toes.	817
41, The flesh of the entrals or bowels.	820
42, What a glandule is, and how many kinds there be of them.	821
43, A brieft enumeration of the Glandules in the whole body.	823

The eleuenth Booke.

CHAP. I.

V What a veine is.	825
2, Of the vse & action of the veines.	827
3, The differences of yeines.	828
4, The description of the gate veine and his bran-ches.	831
5, Of the descending Trunke of the hollow veine.	835
6, Of the ascending Trunke of the hollow veine.	839
Folio	839
7, The veines of the Face, the eyes, the nose, the teeth, and the throttle.	843
8, Of the veines disseminated thorough the braine.	844
Folio	844
9, Of the veines of the whole hand in the large ac-ception.	845
10, Of the veines of the whole foot, in the large ac-ception.	849
11, The values and floudgates of the veines.	852
12, Of the arteries in generall.	856
13, Of the vse of the arteries.	859
14, Of the ascending trunk of the great artery.	860
15, The descending trunk of the great artery, ac-companying the hollow veine.	862
16, The arteries accompanying the branches or the gate veine, through the lower belly.	864
17, Of the arteries of the Braine.	865
18, The arteries of the Face, the eyes, the nose, the teeth, and the <i>Larynx</i> .	867
19, Of the arteries of the hand in the large accepta-tion.	1b.
20, Of the arteries of the foot in the large accepta-tion,	869
21, Of nerues in generall.	871
22, The nerues of the eyes, or of the first and second coniugation.	876
23, Of the third and the fourth coniugations of the braine.	889
24, Of the Auditory nerue or the fift Coniugation.	891
25, Of the sixt seuenth and eight Coniugations.	892
26, Of the nerues which issue from the spinall mar-row in the necke.	894
27, Of the nerues of the Chest.	897
28, Of the nerues of the Loynes.	898
29, Of the nerues of the Holy-bone.	899
30, Of the nerues of the hand in the large accepri-on.	900
31, Of the nerues of the foote in the large accepti-on.	904

The twelfth Booke.

CHAP. I.

O f the definition, vse, and difference of grif-tles. Folio	907
2, Of the gristles of the Face.	909
3, Of the <i>Epiglottis</i> , the Gristles of the <i>Larynx</i> , and of the weazon.	910
4, Of the gristles in the trunk or bulke of the bo-dy.	912
5, Of the gristles of the Ioynts.	913
6, Of	918

The Table.

6, Of the nature, vse, and differences of Ligaments.	1b.	9, Of the suture and seames of the vpper Iaw.	952
Folio		10, Of the bones of the vpper Iaw.	954
7, Of the ligaments of the head.	915	11, Of the lower Iaw.	957
8, Of the Ligaments of the spine and the chest.	1b.	12, Of the sockets of the teeth.	959
9, Of the ligaments of the shoulder blade, the arme		13, Of the name, definition, figure, magnitude,	
the cubit, and the wand.	916	number, site, and articulation of the teeth.	960
10, Of the ligaments of the wrest, afterwrest and		14, Of the shears and Dog-teeth.	962
the fingers.	917	15, Of the grinding teeth.	963
11, Of the Ligaments of the Holy-bone, the han-		16, Of the vessels and fence of the teeth.	965
ches, and the whole leg and foote.	918	17, Of the inward cavity and membrane of the	
12, What a membrane is, their vses and differences.	920	teeth.	968
13, A briefe enumeration of al the membranes.	922	18, Of the generation and vse of the teeth.	969
14, The nature of fibres.	923	19, Of the bone <i>Hyois</i> called <i>os guinnia</i> .	972
15, Of the differences of fibres.	1bid.	20, Of the spine in generall.	974
		21, Of the rackebones of the necke.	976

The thirteenth Booke.

CHAP. I.

OF the definition and difference of bones.	926	22, Of the racks of the backe, the loynes and the	
2, Of the parts of bones and their appellati-		holy-bone.	977
ons.	928	23, Of the bones of the chest in generall.	981
3, Of the structure and connexion of bones in gene-		24, Of the clauicles or collar-bones.	1bid.
rall.	930	25, Of the brest bone.	983
4, A briefe definition and enumeration of all the		26, Of the Ribs.	984
bones in the body.	936	27, Of the shoulder blade.	985
5, Of the sutures or seames of the scull, and of the		28, The hip, hanch and sharebones.	986
substance thereof.	937	29, The bones of the arme and the cubit.	988
6, Of the proper bones of the scull.	941	30, Of the bones of the hand properly so called,	
7, Of the bones that are common to the head and		that is, of the wrest and afterwrest.	992
the vpper Iaw, that is to say, of the wedge and		31, Of the bones of the fingers.	995
spongy bones.	947	32, Of the Seed-bones.	996
8, Of the bones of the nose, and of the yoke bone.	951	33, The boues of the thigh,	997
		34, The two bones of the leg,	1000
		35, The whirle bone of the knee.	1002
		36, The bones of the Foote properly so called, and	
		particularly of the wrest of the Foote.	1005
		37, The bones of the afterwrest, and the Toes of	
		the feet.	1007
		38, Of the Seede-bones and the nayles.	10010

THE FIRST BOOKE.

The Præface.

THE worth and excellencie of an Art, is greater or lesse, according to the dignitie or basenesse of the Obiect, whereabout it is conuersant. So in the *ἐγκυκλοπαιδεία*, that is, the Orbe or Circle of the Arts, *Logicke* is worthily esteemed the first in order, because the Obiect thereof is *Reason*; whereby (as by *Ariadnes* clew) we are directed through all the intricate Labyrinths and Mazes of Nature; and *Diuinitie* the last and most excellent, as being the end and consummation of all the rest, teaching vs how to liue blessedly both here and for euer: and therefore though all Arts be indeed originally from God, yet this is said more properly to be *ἀποθεῖ κατεργασμένη*, because it is immediately deliuered, and that by inspiration from Heauen. Betwixt these two, there are many Arts full of secret and obstruse notions, deepe mysteries and high contemplations, yet none, me thinks, that can stand in competition with this we haue in hand concerning the frame of Man. For to let passe the rest; if it shall be objected, That the infinite extent, the absolute and circular figure, the perpetuall and rapid motions of the Heauens, the glorious Bodies wherewith they are spangled, the sweet harmonie of their Spheares, the powerfull influence of euerie Starre (the least of which is said to be eightene times as bigge as the Earth) as they are in heighth and magnitude, so they are in dignitie farre aboue the nature of Man: If for the Earth it shall be said, that it is the rich Matter and Matrix, the great Mother and Nurse of all Creatures; the Spouse of Heauen, in whose onely bosome (as in their proper Center) all the influences of the heavenly Bodies doe concur and vnite themselves, lesse subiect to
B alteration

alteration then Heauen it selfe, if we beleue Astronomers; immouable and yet in perpetuall motion; by the continuall corruption and generation of things, alwayes consuming yet neuer diminished. If a Common-wealths-man shall preferre the Art of Policie, whereby not onely particular Men, but Cities, Kingdomes, Empires, yea and the whole World is kept in order which otherwise would run head-long to confusion; this being an Image of Gods gouernment and the verie Character of his administration in punishing Vice and rewarding Vertue: If, I say, any Man shall preferre the knowledge of any of these to the mysterie of the Humane Nature, I would haue him esteeme; that there is nothing either in Heauen or on Earth, or in the administration of them both, not only on Mans part, but which is more, on Gods also, that is not equalled, yea the Diuine historie giueth vs warrant to say, exceeded in the frame of Man. For, whereas in the Creation of the Heauens & the Earth, and the furnitures and armies of them both, the great Architect wrought them all by his thought, word and deed, all falling into one instant of time:

Genes. 1. 23.

When he was to make Man, he holds a Councell, *Come let vs make man according vnto our owne Image*; summoning thereunto, not onely himselfe and all his attributes, as his Power, his Wisedome, his Iustice, his Loue & Mercie, if not to cast in some part, yet to lend some influence of their Diuine Natures towards his creation; but also his Son and the blessed Spirit: as if Man were a kind of production of the whole Deitie, or as the Poet saith,

Virg. Eclog. 4.

As. 17. 27.
Rhemusam.

Magnum Iouis incrementum; which I am the rather bold to say, because the learned Apostle vsurpeth the verie words of another Poet to the selfe-same purpose, *αὐτὸν γὰρ καὶ γένος ἰσμεν*, we are also of his off-spring; not that I conceiue (as some blasphemously haue done) that he was made out of the verie Essence of God, but because the Image of the Diuine Nature, is most liuely imprinted in his Soule and in his Body, and in the substance and qualities of them both. For the Soule, it carieth a deepe stampe of Diuinitie in the simplicitie, inuisibilitie and immortalitie thereof: That it is incorporeall & diffusiue, quickning, sustaining, gouerning and moving the whole Body and euerie part thereof, euen as God supporteth and ruleth the whole world being by a diffusiue nature, or rather infinite omni-presence at all times, in euerie place: That as the Deitie is but one in Essence, yet distinct in Persons, according to the Relative qualities therein, which yet hath neither different matters, nor formes (as we say) but are all one and the same Essence; so the Soule of Man is but one, yet that one, consisting of three essentiall and distinct Faculties or Powers, intellectuall, sensitiue and vegetatiue; which yet make no difference in the substance thereof, that it should not be one and an entire Soule. Againe, in the intellectuall part or power, there are two essentiall Attributes resembling their Prototype or originall in God, to wit, Knowledge and Will. As for the qualities of the Soule, they are either internall, or externall. The internall carie the Image of the Creator, as *S^t Paul* interpreteth it, in heauenly Wisedome, Iustice and Sanctitie; the externall, in Maiestie, Dominion and Soueraigntie ouer the Creatures; both which, the Poet hath excellently put together, where he speaketh of Mans creation, after the rest of the Creatures.

Colos. 3. 10.

Ouids Metam.

*Sanctius his Animal, mentisq; capaxius altæ
Deerat adhuc, & quod dominari in cetera posset,
Natus homo est.*

A Creature holier then the rest, and better fram'd to hold
A Soule infused from aboue was wanting yet; So borne
At length was Man, the rest in bands of awefull power to fold.

Aulius.

The Body also, as far as it was possible, carieth the Image of God, not in figure, as *Aulius* and his followers, the *Anthropomorphites* haue sottishly dreamt (he being an infinite Ocean of Essence, transcendent and aboue all comprehension of nature or time: which himselfe expresseth to *Moses* in the future tense of the substantiue verbe, *Ero*; signifying thereby, the present and eternall subsistence of a subiect, without any prædicate as we say in Schooles) but because the admirable structure and accomplished perfection of the Body, carieth in it a representation of all the most glorious and perfect workes of God, as being an Epitome or compend of the whole Creation, by which he is rather signified then expressed. And hence it is, that Man is called a *Microcosme* or little world, as in the following discourse will more at large appeare; to which with this short preamble as a Preface of Honour, we referre the Reader.

CHAP. I.

The excellencie of Man is declared by his parts, namely, the Mind and the Body, and first what is the dignitie of the Soule.

IN the Inauguration or Coronation of a Prince, there is nothing more stately or magnificent, then to haue his stile rehearsed by Men of greatest Nobilitie, euerie one adding some-what thereto, till the whole number of his Seigniories and Honours are heaped vpon him: If therefore, we list to search what and how magnificent haue been the acclamations of all ages, we shall find in the Records of Antiquitie, that Man, in whom the sparkes of heavenly fire, and seeds of the Diuine Nature are (as appeareth both by the Maiestie imprinted in his face and by the frame of his Body, which was made vpright and looking toward Heauen) was of the wise and prudent Priests of the Egyptians, stiled a reuerend and admirable Creature. That thrice-worthy Mercurie calls him *A great Miracle, A Creature like the Creator, The Ambassador of the Gods.* Pythagoras, μέτρον ἀπάντων, *The measure of all things.* Plato δαίμα δαυμάτων, *The wonder of wonders.* Theophrastus, *The patterne of the whole Vniuerse,* ἀντίμωρον παρὰ δαίμονα. Aristotle, *A politike Creature framed for societie.* Symesius, *The Horizon of corporeall and incorporeall things.* Tully, *A diuine Creature, full of Reason and Iudgement.* Pliny, *The worlds Epitome and Natures Darling.* Finally, all Men with one consent, call him, μικρόκοσμον, or, *The little world.* For his Body is, as it were, a Magazine or Storehouse of all the vertues and efficacies of all Bodies, and in his Soule is the power and force of all liuing and sensible things. That ancient Zoroaster, hauing long admired the singular workmanship shining in the frame of Man, at length cryed out, Ὁ ἄνθρωπος, πληροτάτης τῆς φύσεως ἀγαθία. *O Man, the glorie of Nature, even in her chiefest ruffe and pride, and her master-peece, when she durst contend with Heauen it selfe.* Abdolus the Barbarian, being asked what he thought was the most admirable thing in Nature, is reported to haue answered, not barbarously, but wisely; *It is onely Man who farre surpasseth all admiration,* because being the Image and resemblance of the whole world, he can suddainly (Proteus-like) transforme himselfe into any particular thing. Fauorinus did acknowledge nothing great vpon Earth, but Man.

The Diuines call him *Omnem Creaturam, Euerie Creature*, because he is in power (in a manner) *All things*; not for matter and substance, as Empedocles would haue it, but *Analogically*, by participation or reception of the seuerall species or kinds of things. Others, call him, *The royall Temple or Image of God.* For as in Coyne the picture of Caesar, so in Man the Image of God is apparently discerned. Others, call him, *The end of all things* (which in Nature is the first cause) to whom all sublunarie created Bodies & Spirits are obedient, yet he himselfe subiect vnto none, vnlesse peraduenture one Man come vnder the Lee and subiection of another. The kingly Prophet David, full of heavenly inspiration, desciphereth the dignitie of Man on this manner; *Thou hast made him little lower then the Angels, thou hast crowned him with glorie and honor, and giuen him dominion ouer the workes of thy hands.*

These are excellent, that I may not say diuine commendations, which Man hath, partly from his Soule, the most excellent of all formes; partly from his Body, which is as it were the measure and exemplarie patterne of all corporeall things. The Soule indeed is so diuine, that rayning and mounting it selfe sometimes aboue all naturall formes, it comprehendeth by an admirable, absolutely-free and incompulsue power, all incorporeall things seuered and diuided from all matter and substance. This Soule, if it could be discerned with the eye, or but conceiued by the mind, how would it rauish vs and lead vs into an excessiue loue of it selfe? Onely this is created, not generated; and albeit (as the Philosophers speake) there be a subiect supponed in her production, yet it is not produced out of the power of that supponed matter, but rather absolueth and perfecteth the same.

This onely is indiuisible, for all other naturall formes receiue augmentation, diminution and diuision, together with their subiects; but the Soule of Man is *wholly in the whole, and wholly in euerie particular part.* This onely is immateriall, herein alone participating with the Matter, that it is capable of all species or kinds, even as the *First matter* admitteth all impressions and formes; and yet the manner of reception is not alike in them both. For that *First matter* receiueeth but particular and indiuiduall formes, and that without vnderstanding: In the Soule are imprinted the vniuersall formes of things, and it hath

How the reception of formes differs in the first Matter, and in the Soule. The Soule is the place of the Species or formes.

Aristotle. Plato. The Soule is in the middle degree of all things. The nature of the Soule is Angelicall.

In the Soule appeareth the image of the Trinitie.

Symonides

Hippocrates

also vnderstanding to iudge of them. The *First matter* admitteth those particular formes materially, and withall obliterateth or blotteth out the contrarie forme whereof it was before possessed: The Soule of Man receiues and entertaines the generall and vniuersall notions of things, free from all contagion or touch of Matter, not abolishing the contrarie or diuers formes whereof before it was possessed. This alone is incorporeall, immortall, *ἀνάντητος* or immutable. This may be called the receptacle, promptuarie or Store-house of all the species or kinds of things.

Aristotle in his third Booke *De Anima*, calleth it, *After a manner all things, Because* (saith he) *in an organe of sense, the sensible species or images of things are blotted out and as it were drowned, but the Soule retaineth them.* The Platonists doe range it in the mid'st, as hauing God about it, and the *Intelligences* or Angels: below it, all bodyes and all qualities, that so it might be partaker of them both. According to Diuines, it approacheth verie neere to the nature of Angels, by reason of her vnderstanding or intellectuall power, of her originall, eternitie, image, apprehension and beatitude.

To conclude, there is in the Soule of Man something Metaphysicall, transcendent aboue Nature, vnkowne to the ancient Philosophers, who groped but in the darke, hauing their conceits enuoloped in a mystie or cloudy veile of ignorance; and is reuealed onely to Christians, to whom the light of the Gospel hath shined. For in it is a liuely resemblance of the ineffable Trinitie, represented by the three principall faculties, *Memorie, Vnderstanding and will.* But stay: Why should I presume to describe the Essence of the Soule, seeing it partaketh of so much Diuinitie? For of diuine things *Symonides* hath said well, We can onely say what they are not, not what they are. Why should I paine my selfe to open that shrine which Nature her selfe hath veyled and sealed vp from our senses, lest it should be prophaned by them? Hence it is, that *Hippocrates* calleth it *ἀόρατον ἀφανές*, *The in-aspectible or inuisible Nature*, which can no more be described by vs, then our eye is able to see it selfe. These things therefore belong to a higher contemplation, and require a more skilfull workeman to draw but the lines, or euen to shadow them out. Let vs content our selues to handle that which may be handled, or at least is subiect vnto some of our senses, and so proceed to the other part of Man, namely, the Body, which more truely and properly is the subiect of our discourse.

CHAP. II.

Of the dignitie and wonderfull frame of Mans body.

The excellencie of Mans body is set forth by foure things.

I. An vpright frame. Plato in *Cratylus*.

Of the vpright frame the efficient cause is two-fold.

AS the Soule of Man is of all sublunarie formes the most noble, so his Body, the House of the Soule, doth so farre excell, as it may well be called *μέτρον*, the measure & rule of all other Bodies. There be many things which set forth the excellencie of it, but these especially. First, The frame and composition which is vpright and mounting toward Heauen; the moderate temper, the equall and iust proportion of the parts; and lastly, their wonderfull consent and mutuall concord as long as they are in subiection to the Law and rule of Nature: For so long in them we may behold the liuely Image of all this whole Vniuerse as it were shadowed in a Glasse, or desciphered in a Table. And first for the Figure. Man onely is of an vpright frame and proportion, whereupon he is called of some *ἐρανοσκόπος*, vsually *ἀνθρώπος*, as it were *ἀνὰ θεῶν*, looking vpwards; although *Plato* in *Cratylus* is of opinion, that Man is called *ἀνθρώπος*, as it were *ἀνὰ θ' ἑντὶ α' ὀπῶν*, that is, contemplating those things which he seeth. The reason of this forme or figure, is meere Philosophicall, as depending vpon the Efficient, Materiall and Finall causes. The Efficient is two-fold, Primarie and Secundarie: The Primarie, is the Soule, which comming from without, and being infused into the Body from Heauen, whilst she is building a mansion fit for such functions and offices as she hath to performe, as mindfull of her owne Originall, listeth her building vp on high.

The Secundarie Efficient of Mans body, is Heat, wherewith Man aboue other Creatures aboundeth, especially the parts about his heart. The nature therefore of heat preuailling, forceth the increment or growth, vp from the middle part, according to his impetuous strength and nimble agilitie, that is, it striueth and driueth toward that part of the world, toward which heat is naturally moued, that is to say, vpward. For the Matter of Mans

Mans body, thing and to The Finall cause and proportion. Anaxagoras and the Stars all placed as preference-chances ner be exercised which is hum for contempt storie of the the better he the vapor th keep watch Distances an an vpright had an vpr given him Now if th should hau noble a diti ride, live in throw all groueling Wherefor this cause shion of fore the Creatur altogether the backe Figure. Man hat as being th either too Plants and middle of the cording to hath includ in their seu vnto Man- the heart of number of a solute Temp maged, as w extremes, been made a sublunarie at uerall specie knowledge tyed to app outward sent the ministry the Soule; it as might be hath his eff whence it is

Mans body, it is soft, plyable and temperate, ready to follow the Workeman in euerie thing and to euerie purpose; for Man is the moystest and most sanguine of all Creatures. The Finall cause of the frame of Mans body is manifold. First, Man had an vpright frame and proportion, that he might behold & meditate on heavenly things. And for this cause *Anaxagoras* being asked wherefore he was borne, he made answer, to behold the Heauens and the Starres. Secondly, that the functions and offices of the outward senses, which are all placed as it were a Guard in pension in the palace of the head, and in the view and presence-chamber of Reason, which is their Soueraigne, might in a more excellent manner be exercised and put in practise: For they were not ordained onely to auoid that which is hurtfull, and to follow and prosecute that which is profitable; but moreouer also for contemplation: and therefore they were to be placed in the highest contabulation or storie of the Body. And by this meanes, speech (which is the messenger of the mind) is the better heard from on high; the smell doth more commodiously receiue and entertain the vapor that ascendeth; the eyes being as it were spies or centinels day and night to keepe watch for vs, and being beside giuen vs that we should take view of those infinite Distances and glorious Bodyes in them which are ouer our heads, did therefore require an vpright frame and composition of the Body. Finally, to conclude this point, Man onely had an vpright frame of Body, because he alone amongst all Creatures had the Hand giuen him by God, an organ or instrument before all organs, and indeed, in steed of all: Now, if the figure of Man had been made with his face downeward, that diuine Creature should haue gone groueling vpon his hands, as well as vpon his feet, and those worthy and noble actions of his Hand, had been forfeited, or at least disparaged. For, who can write, ride, liue in a ciuill & sociable life, erect Altars vnto God, build Ships for war or traffick, throw all manner of Darts and practise other infinite sorts of excellent Arts; either groueling with his face downeward, or sprawling on his backe with his face vpward? Wherefore, onely Man had the frame of his Body erected vpward towards Heauen. For this cause also, onely Man amongst all other Creatures was framed according to the fashion of the whole vniuerse, because he hath his parts distinct, the vpper the neather, the fore the backe-parts, those on the right-hand and those on the left-hand; the rest of the Creatures either haue them not at all, or verie confused. The right-parts and the left are altogether alike sauing that the left are the weaker; but the fore-parts are verie vnlike the backe-parts: the lower in some sort carie a resemblance of the vpper: so much of the Figure.

Man hath likewise a moderate Temper, and is indeed the most temperate of all Bodies, as being the μέτρον, measure and rule of all others. The Bodyes of other Creatures, are either too Earthy, or too Watry: but to Mans, the temperature of all things liuing, both Plants and Creatures is referred as to the *Medium generis*, as we vse to say, that is, to the middle of the whole kind, so that they are said to be hot, cold, moyst and dry *πρὸς τὸ μέτρον*, that is, according to Reference; their temperature being compared with Mans. Againe, Man alone hath included in himselfe the temperature of all liuing things; all other Creatures are in their seuerall kinds (for the most part) of one and the same temper: but if you looke vnto Man-kind, you shall find some that haue the stomach of an Estrich; others that haue the heart of a Lyon: Some are of the temper of a Dog, many of a Hog, and an infinite number of as dull and blockish a temper as an Asse. This also declareth the *ὑπερβολή*, or absolute Temper of Mans body, that it is subiect to many diseases, and is equally endamaged, as well by one extreame, as by another; because it is equally distant from both extreames. There might indeed of the heavenly Matter (being the most noble) haue been made a Body most noble also; but it was of necessitie our Body should be made of sublunarie and elementarie matter, that it might be capable and apprehensue of the seuerall species and formes of things which moue the senses, because from them all our knowledge is deriued. For Man being borne to vnderstand, and he that vnderstandeth, tyed to apprehend those visions and fantasies which are objected either to the inward or outward sense; and there being no perception of any such vision or imagination, but by the ministry of the outward senses, which are the intelligencers betweene the Body and the Soule; it was necessarie that the Body of Man should be composed of such a matter as might be capable of these senses; but of all Senses the foundation is *touching*, which hath his essence and being in the temper and moderation of the foure first qualities: whence it is, that the foure first substances wherein those qualities doe reside, were

The materiall cause.

The finall cause threefold.

Anaxagoras

Man alone framed according to the fashion of the whole World

2

The excellencie of the body is likewise set forth in the temperature.

Man alone hath in himselfe the temperature of all liuing things.

Why the body of man was not made of an heavenly matter, but of an elementarie

necessarily to be the matter of the Body, and those are the foure Elements. And so much of the temperature of Mans body.

3
The admirable proportion of the parts

The circular and square figure appearing in Mans body.

Archimedes quadrature of the circle found in mans body.

4
Man containeth in himselfe all things in the whole world.

Three parts of the world.

The collation of Man with the world.

The elegant Analogie betwene the Sunne and Mans Heart.

Aristotle

Now the *συμμετρία* or due proportion, composition or correspondencie of the parts of Mans body, with respect each to other, and of them all to the whole, is admirable. This alone (for a patterne) doe all Work-men and Arts-masters set before them: to this, as to *Polycletus* rule, doe the Surueighers, Master-Carpenters and Masons, referre all their plots and proiects; they build Temples, Houses, Engines, Shipping, Forts, yea and the Arke of *Noah* (as it is recorded) was framed after the measure and proportion of Mans body; for, as the Body of a Man is in length 300 Minutes, in breadth 50, and in heighth 30; so the length of the Arke was 300 Cubits, the breadth 50 and the heighth 30. Moreover, in this proportion of his parts, you shall find both a circular figure, which is of all other the most perfect; and also a square, which in the rest of the Creatures you shall not obserue. For the nauell being placed in the middle of the whole Body, and as it were in the center; if you lay a Man vpon his backe, and as much as may be labour to spread both his hands and feet, and keeping one end of the compasse vnmoued and set vpon his nauell, doe turne about the other end, you shall come vnto both the thumb-toes of the feet and the middle fingers of the hands: and if in any part this proportion faile, you may imagine there is a defect in that part. Also, if you conceiue a measure betweene the feet spread abroad, and likewise betweene the hand and the foot on either side, you shall haue a perfect quadrat drawne & portrayed within that circle. And this is the true quadrature of the circle, not those imaginarie lines whereof *Archimedes* wrot, and which haue troubled the heads of all our Mathematicians for many ages, when as euery one might haue found it in himselfe.

These be excellent things which we haue obserued, touching the figure and frame of Mans body, the temperature thereof, and the proportion of the parts; but this last exceedeth all admiration, that in it selfe alone, it should containe all whatsoeuer this whole world in his large & spacious bosome doth comprehend; so as it may worthily be called a Little world, and the paterne and epitome of the whole vniuerse. The ancient Magicians (for so naturall Philosophers were of old termed) as also the great wise Priests of the *Egyptians*, did make of this whole vniuerse, three parts: The one, Vppermost or superior, which they termed the Intellectuall and Angelicall part, the seat of the *Intelligentie* (so they called the Spirits, which by tradition from the *Hebrews*, they vnderstood were in the Heauens) by whose direction and command, the inferiour or lower world is guided and gouerned: another Middle, which they termed the heavenly part, in the midst whereof the Sunne ruleth, as the Leader and moderator of the rest of the Starrs: the third, Sublunarie or Elementarie, which is admirably & abundantly fertile, in procreating, increasing and nourishing of Creatures and Plants. The images and resemblances of which three parts, who seeth not plainly expressed and as it were portrayed out with a curious penfill in the Body of Man? The head, the castle and tower of the Soule, the seat of Reason, the mansion-house of Wisdome, the treasurie of Memorie, Iudgment and discourse, wherein Mankind is most like to the Angels or Intelligencies, obtaining the loftiest and most eminent place in the Body; doth it not elegantly resemble that supreme and Angelicall part of the world? The Middle and Coelestiall part is in the brest or middle Venter most exactly and euen to the life expressed. For as in that coelestiall part the Sunne is predominant, by whose motion, beames and light all things haue their brightnesse, luster & beauty; so in the midst of the chest the heart resideth, whose likenesse and proportion with the Sunne is such and so great, as the ancient Writers haue been bold to call the Sunne *The Heart of the world*, and the Heart *The Sunne of Mans body*. For euen as by the perpetuall and continuall motion of the Sunne, and by the quickning and lively heat thereof, all things are cheered and made to flourish; the Earth is decked and adorned yea crowned with Flowers, brings forth great varietie of Fruits, and yeelds out of her bosome innumerable kinds of Hearbs; the Shrubs thrust forth their buds or iems and are clothed with greene leaues in token of iollitie; all Creatures are pricked forward with the goads and prouocations of Lust and so rushing into Venereall embracements, do store and replenish with a large and abundant encrease, both Cities, Land and Seas; (for which cause, *Aristotle* calleth this prosperous, refreshing and comfortable Starre *γεννητικὴν*, as being the procreator of all things) and on the contrarie, the same Starre or Sunne being departed far from our Coasts, the Earth begins to be horrid and looke deformed, the Shrubs are robbed and dispoyled of their leaues, berries and verdure; and a great part of those things which the

fertilitie of Nature had brought forth, is weakned and wasted : so in like manner, by the perpetuall motion of the Heart & by the vitall heat thereof, this Little world is refreshed, preferred and kept in vigor and good life ; neither can any thing therein be either fruitfull or fit and disposed to bring forth, vnlesse that mightie and puissant power of the Heart doe afford and yeeld an effectuall power of Fecunditie. The Vitall facultie floweth from the Heart as from the Fountaine, the coelestiall facultie from Heauen. This later, is said to be the preseruer of all inferior things : the former kindleth, nourisheth and refresheth the naturall heat of euerie part. The Heauen workes vpon the inferior world by his motion and light ; the Heart by his continuall motion & æthereall spirit, as it were a bright light, cleareth and beautifieth all the parts of the Body. The motion & light are in the superior Bodyes the instruments of the Intelligencies and of the Heauens ; of the Intelligencies as of the first mouers vnmoued, of the Heauens as of the first mouer moued. The Vitall spirits and pulsation or beating of the Heart are instruments of the Soule and of the Heart : of the Soule as of a mouer not moued ; of the Heart as of a mouer moued by the Soule.

The excellent
similitude of
the vitall and
coelestiall
faculties.

Now further, who seeth not the sublunarie part of the world expressed in the inferiour venter or lower belly ? For in it are contained the parts that are ordained for nourishment and procreation ; so as we need not make any doubt to profess and affirme, that all things are found in the Body of Man, which this vniuersall world doth embrace & comprehend. Wilt thou see in this *Microcosme* or little world the wandring Planets ? The moyst and watry power of the Moone is resembled by the streaming marrow and pith of the backe and braine. The power of *Venus* is proportioned in the generative parts. To *Mercurie* so variable and withall so ingenuous, the instruments of eloquence and sweet deliuerie are answerable. Of the Sunne and the Heart, the admirable proportion and agreement, we haue already declared. To the beneuolent and beneficall Starre *Iupiter*, the liuer of Man, the well-spring of most sweet and gratefull humors is fitly compared. The fire and furie of *Mars*, the little bladder of the gaule gathers into it selfe. The cold and harmfull Starre *Saturne*, that loose and flaggie flesh of the spleene, being the receptacle of melancholike humours, doth liuely resemble. And thus in like numbers and equall proportion, both Arithmetically and Geometrically, doe these Coelestiall particles (as they are termed) of either world, the greater of Heauen and the lesser of Man, answer one another. The twelue signes of the Zodiacke, by the Astrologers elegantly depicted in the Body of a Man, I passe over with silence : for these are things ancient and commonly knowne, as being fung in the corners of our Streets : we choose rather to meditate of more sublime and profound matters and to bend the eye of our mind at a higher marke. The *Peripatetikes* doe diuide the world into Bodyes simple and mixt ; simple they make five, the Heauen and the foure Elements ; of the mixt Bodyes, they will haue some to be imperfect, which they call Meteors, and those Fierie, Aerie, Watry, Earthy : other some perfect, as those things that haue life. All which, how and after what manner they be in Man, because it is an excellent and beautifull speculation, I pray you marke and obserue with me diligently. Of this Little world, the simple Bodyes are five, the spirits & the foure humors. The Spirit is the quintessence or fifth essence, æthereall, in proportion (as saith the Philosopher) answering to the Element of the Starres ; the foure humors are called the foure sensible Elements of the Body. Choler in temper the most hot and raging resembles fire. Blood hot and moyst resembles the aire. Flegme cold and moyst resembles the water. Melancholy cold and dry is fitly compared vnto earth. Behold also the wonderfull Analogie of the Meteors of this Little world. The terrible lightning fierie flashes and impressions, are shewed in the bloody suffusions of our eyes when we are in a heat and furie, as also by those *ελαμψεις* or darting beames which we throw from the same. The rumbling of the guts, their croaking murmurs, the rapping escapes and the hudled and redoubled belchings of the stomach, doe represent the fashion and manner of all kinds of thunders. The violent and gathering rage of blustering winds, tempestuous stormes and gusts, are not onely exhibited, but also fore-shewed by exhaled crudities and by the hissing, singing and ringing noyses of the eares. The humor and moistnesse that falls like a current or streame into the emptie spaces of the throat, the throtle and the chest, resembleth raine and showres. Thicke and concocted flegme, that comes vp round and roundly when we cough, carries the likenesse of haile-stones ; teares doe represent the dew : shaking, shrinking, trembling and throbbing motions, resemble the earth-quakes. There are also found

in our Bodyes, mines and quarries, out of which mettals and stones are digged, not to build, but to pull downe the House; so the stones of the kidneys and bladder doe carie a resemblance of Mines and Minerals.

Perfect
exaltation.

This is the Meteorologie of this Litle world, this is the demonstration of those things therein that are imperfectly mixed. And if you require in Man an example of a Body perfectly mixed, behold and consider the whole Body; in which, there is that concord and agreement of the foure disagreeing qualities, and so iust and equall a mixture of the Elements, as that it is the verie middle & meane amongst all liuing and animated things. This Litle world therefore, which we call Man, is a great miracle, and his frame and composition is more to be admired and wondred at, then the workmanship of the whole Vniuerse. For, it is a farre easier thing to depaint out many things in a large and spacious Table, such as is the world; then to comprehend all things in one so litle and narrow, as is the compasse of Mans body.

• CHAP. III.

EPICVRVS, MOMVS, and other the malicious and false detractors from Nature are censured, and the excellencie of Man is demonstrated by his nakednesse.

Et that beastly *Epicure's* mouth be now sealed vp in dumbe silence, who was not ashamed to affirme, that the Bodyes of Men were made by chance and fortune, out of a turbulent concourse (forsooth) of a number of Atomies or Motes, such as we see in the Sunne. Let *Momus* be hissed and exploded, but first mark't with a blacke brand of ignorance and infamie, who presumptuously blamed in the frame of Mans body many things, as lame, mamed and vnperfect. Let all the whole rabble of doting Philosophers, be banished out of the Schoole of Nature, who cease not to wrong and traduce her, for casting forth Man naked and vnarmed on the bare ground vpon his Birth-day, to begin the world with crying and lamentation. For to begin with the *Epicure*: Those things which come by chance (O *Epicure*) happen but sildome, and of such things neither any certaine, nor any prosperous euent can constantly be expected or hoped for: but if thou doest heedfully obserue 1000 Men, thou shalt find all their Bodyes made and framed with equall skill and vnmachable art; the same structure of Bones, Cartelages, ligaments, Sinewes, Veines, Arteries and Entrals; the same context and composition, figure or fashion, number and scituation: The right-side like vnto the left; and all the Body within one and the same circle and compasse equally poysed; so that nothing in the frame of Mans body doth thrust it selfe in by chance, nothing there is that doth not exhibite and represent vnto vs the Maiestie of the highest and most heauenly Wisedome.

The error of
the *Epicures*
conuincied.

Galen.

Galen, to conuince the error of this beastly *Epicure*, said, He would giue him an hundred yeere to conceiue an alteration or change of the scituation, figure or composition of any one part, and he did not doubt, but it would come to passe in the end, that he would be forced to confesse, that the same could by no meanes haue been made after any more perfect manner. I will speake some-what more boldly; If all the Angels should haue spent a thousand yeeres in the framing and making of Man, they could not haue cast him in so curious a mold; or made him like to that he is, much lesse could they haue set him forth in any better manner. Let the *Epicure* therefore be packing with this false fiction and feigned inuention of his owne addle braine. As for *Momus*, he is to be scorned for his dotage and simplicitie, who wished Mens bodyes had been made full of windowes, that the affections of the mind might haue appeared. Why *Momus*? Doe not all the passions of the mind appeare plainly characterized in the face & in the eyes; so that he which runs may read them? The eyes are the discouersers of the mind, as the countenance is the image of the same; by the eyes as by a window, you may looke euen into the secret corners of the Soule: So that it is well said of *Alexander*, ὁφθαλμοὶ τῆς ψυχῆς πάλσιπρον εἶναι, that the eyes are the mirror or looking-glasse of the Soule. The eyes wonder at a thing, they loue it, they desire it; they are the bewrayers of loue, anger, rage, mercie, reuenge; In a word; The eyes are fitted and composed to all the affections of the mind, expressing the verie image thereof in such a manner, as they may seeme to be euen another Soule; and therefore

The slander
of *Momus*
condemned.

Alexander.

when

when we kisse the eyes, we seeme to reach and diue euen to the verie Soule. And for the face, how many signes are there in it, and those verie manifest and apparent, of a sorrowing, fearing, couetous, wrathfull and pleasant mind? In the whole countenance, audaciousnesse, shamefastnesse and maiestie are euident and conspicuous. For in the eye-browes dwelleth pride, in the cheekes shamefastnesse, in the chin maiestie: All these are bred in the heart, but here they haue their seat and residence, hither they betake themselves, hereupon they depend.

Their insolencie is also to be restrayned, who call Nature a cruell step-mother, because she casts forth Man into the world altogether naked and vnarmed both in Soule & Body; and therefore hold him to be of all Creatures the most imperfect. And of the nakednesse of the Soule, thus they discourse. Other Creatures (say they) doe perceiue and vnderstand their owne nature; some betake themselves to the swiftnesse of their feet, some trust to the loftinesse of their flight, some to swim in the waters; Man knoweth nothing, neither how to speake, nor how to goe, nor how to feed: And in a word, that Creature which is borne to rule and gouerne all the rest, is enclined by Nature to nothing else but mourning and lamentation, beginning his life with punishment, and that onely for one fault, to wit, because he is borne. Moreouer, many Creatures goe beyond Man (say they) in perfection of the senses. For in the piercing sight of the eyes, the Eagle; in the quicknesse of smelling and sent, the Dog; in hearing the Foxe and Mole are quicker then we; in tasting, the Hen is sharper; in touching the Spider is more exquisite then we: And so the Soule of Man is more imperfect then that of other Creatures. Let vs heare also the complaints they make of his Body. Nature hath giuen other Creatures diuers couerings, shels, rinds, haire, bristles, feathers, scales, fleeces, hornes, teeth and nailes, whereby they are able both to defend themselves and offend others; onely Man she hath prostituted in his verie natiuitie, altogether vnarmed, naked and vnable to helpe himselfe. They complaine also, that in bignesse of Body we are not equall vnto the Elephants, in swiftnesse to the Harts, in lightnesse to the Birds, in strength and might vnto Bulls, in length of life to the Crowes: That the Beasts of prey haue a skin more solide; the Dooe more slicke and comely, the Beare a skin thicker then ours; and to shut vp all, they say no Creature hath a life more frayle and brittle then Man.

But how ill they reason and how vniust and vnequall valuers they be of diuine blessings, let all Men heare and vnderstand. Surely God euen for this purpose created Man naked, that he might be the Prince and Ruler of all those things that are comprehended within, or subiect to the Law and dominion of Nature. For as the organs or instruments of the senses are void of all strange and externall qualities that they may receiue and entertaine the seuerall species and shapes of all other things; no particular colour there is in the cristalline humor of the eyes, no naturall and inbred sound in the eare, the tongue not falsified with any tast or sauour, the nosethrills haue no proper or particular smell, touching is not possessed of any extreame; right so it was not meet that the mind or soule of Man, which as the Philosopher teacheth, *was in power in a manner all things*, should be preoccupied or taken vp with any particular Art or indowment. The Body also behooued to be naked and vnarmed, that such a Creature as was to gouerne all the rest, should not be tyed onely to one kind of Armor or Weapon: And how incommodious and vnseemly had it been for Man being made for contemplation, alwayes to haue born Armes? Now, he can at his owne will and pleasure, both girt himselfe in all manner of Armor and again presently lay it aside: and therefore, Man is naked, and so it best behooued him to be. But yet God hath not left him destitute euen in this kind, hauing armed him with three seuerall muniments, which he hath denyed to other liuing Creatures; Reason to inuent, Speech to call for assistance, and Hands to bring his will to act and perfection. Reason, is the hand of the Vnderstanding, Speech the hand of Reason, and the Hand it selfe, is the hand of Speech. The hand executeth those things which are commanded, our commandments are subiect and obedient to Reason, and Reason it selfe is the power, force and efficacie of the Vnderstanding. So that in recompence of the nakednesse of the Soule, he hath two helps giuen him, Reason, which is an Art before all Arts; and Speech, the Ambassador or Interpreter of the mind. For the nakednesse of the Body, he hath the Hand, the great Organ before all Organs, and the Instrument of all Instruments. By the power of Reason and of the Hand, albeit Man be borne weake and naked, yet is he secured from all dumbe Creatures; whereas all Creatures whatsoever they be, that are borne and brought

brought forth more firme, yea and more fierce too; howsoever they are able stoutly to endure the force and violence of the Heauens, yet they cannot be secure & free from Man. See now and behold, whatsoeuer thou art, that art a traducer and slanderous detractor from Nature; how bounteous and liberall bequests and legacies this Mother of ours hath bestowed vpon vs; how farre more puissant Creatures, by the ayd of Reason and of our Hands, we haue subdued and brought vnder the yoke; how farre swifter we haue overtaken; neither is there any mortall thing that is not subiected vnder our will and obedience. So then we see, that Reason doth more auaille Man, then any naturall gift doth the dumbe Creature; the volubilitie and readinesse of the tongue and speech, more then the lightnesse and nimble vse of the wings and feathers; the industry of the hands, more then the impetuous force and violence of Bulles, or the teeth or hooues of wild and rauinous Beasts, because they cannot redeeme or free themselves from being oppressed by vs, or acquit themselves from the foueraigntie of our authoritie.

CHAP. IIII.

What the Body of Man differeth from other Creatures, and what it hath proper and peculiar in the composition and frame thereof.

ND now, lest those that are skilfull and learned, should want any thing in our discourse that belongeth to the dignitie of Man, and his admirable and wonderfull frame and composition; let vs proceed vnto such other things, as the diuine Wisedome, the Mother and Gouvernor of all things hath vouchsafed onely to Man, and see in what & how much the Body of Man differeth from the rest of the Creatures. As in Man and other Creatures there is the same manner of life and nourishment, so the frame and structure of the vitall and naturall Organs or Instruments is not vnlike in them both; but for the Senses and power of motion, wherein the Nature of the Animalitie (you must giue leaue to a Philosopher to vse his owne termes) or liuelyhood consisteth, forasmuch as in Man they doe attend vpon, and serue a more noble Forme, and are prepared to more diuine vses, then for the auoyding of euill, and such other obiects of the appetite; it was therefore requisite, that they should haue Organs framed and made with more curious and exquisite workmanship. There are therefore in Man, ouer and besides those things that are already handled, namely, his vp-right Figure and his Hands, which no other Creatures haue; there are, I say, many things in the structure and composition of the animall Organs, proper & peculiar to Man, which doe yet more demonstratiuely proue, yea and expresse also the dignitie of his Body. To run through all, from the Head to the Feet. First, of all liuing Creatures, onely Man hath a Head made into a round and circular forme, as it were turned on a wheele, both that it might be the more capable to receiue a greater quantitie of Braines and lesse apt to be ouertaken with danger either from without or within; as also, for the more ease in mouing and turning about; and lastly, because it was to be the Mansion-house of Reason, that is, the Soule. Now we know, that the Soule was not Traduced but Infused into vs from Heaven, which euen to our sense is round and circular; Seeing then her heavenly habitation is round before she is infused, it was likewise requisite, that her Mansion here below should be orbicular also; yet is the Head of Man not exquisitely round as a Bowle is, but after a sort some-what long also; ryfing vp in the two crownes and on the sides becometh depressed and flatted. Man of all liuing Creatures, hath for his bignesse, a Braine most large and ample, and also verie moyst and watry, the better to performe the varietie of the Animall functions and offices; for the Soule doth not execute hir offices without the helpe of the Spirits: the matter and the substance of the Spirits is Blood, now plentie of Blood is not contained, nor can be concluded within a little and small Body or compass.

The Face is sayd also to be proper vnto Man alone, whereupon the *Greekes* call it *πρόσωπον*, by a name deriued from the thing it selfe, because *πρόσωπον*, it seeth and is seene a farre off; to other Creatures *Nature* hath giuen onely a mouth or a beake: but in the Face of Man, courage, shamefastnesse and maiestie haue their aboad, and therefore Man alone is bashfull & shamefast. At the beholding of this Face, all Creatures are affrighted, because

3.
Man onely
hath a face.

because in it there shine forth more beames of the diuine Nature, then in all the Body besides. This one thing is admirable therein, that whereas in our Face and countenance there are but ten particles, or not many more, yet you shall not find any two among many thousands of Men, that have their countenance in all parts alike, but there is some diuersitie, both in the lines and in the proportion.

Man alone hath his Eyes enamelled with diuers colours, and that in great varietie; whereas other Creatures (the Horse excepted) are in their kinds alwayes alike; so shall you find Oxen to haue all blacke eyes, Sheepe watry, other Creatures red. The eyes of Man are distant one from the other but a very little space, in respect of our proportion of magnitude with other Creatures, that so the Spirits might be the more nimble and more speedily transmitted from one eye to another. Man alone of all Creatures (saith *Pliny*) hath his eyes vitiated and corrupted, yea and sometimes one or both wanting; whereupon came the names or nick-names rather of *Strabo*, one that is squint-eyed or goggle-eyed, and *Patus* for one that hath rouling eyes or squinted vpperward. The haire of the eye-lids are in foure-footed Beasts onely on the vpper lid, in Birds on the neather; Man onely (the Estrich excepted) hath haire both on the vpper and neather lid.

The Nose of a Man is higher and standeth further out then the rest of his Face for decencie and comlinesse; in other Creatures it is not so, but is flatted with the Skull.

Onely in Man the Eares are fixed and immouable, and placed on either side in a right line with the eyes; onely in Man (except it be Apes, which are neere to the proportion of Mans body) are those bones we call *Clauicula* or Cannell bones, which serue to establish the Arme, that in the diuers and sudden motions thereof, it might not be dislocated.

There is no Creature but Man hath Dugges in the fore-part of his Body, the Elephants haue indeed two Dugges or pappes, but not in their Breast.

Those parts which in Man are foremost, that is, on the forepart, as the Breast, the Belly, the Wezon, &c. foure-footed Beasts haue them below next vnto the ground, and those that Man hath on the hinder-part, as the Backe, the Loynes and the Buttocks, Beasts haue them in their vpper parts.

Man of all Creatures is couered with the fewest haire, ylesse it be in his head, which as it is the moystest part of his Body, so also it is the most replenished with haire. Againe in Creatures that are couered with haire, those parts are most hairie that bend downward toward the ground, the rest are either smooth without haire, or not so full of them. On the contrarie, Man is most hairie on the fore-part, because haire was made for a couering; the prone or bending parts of Beasts, stand in need to be couered, yet the foreparts are indeed more noble, but they are cherished & in some sort couered by the bowing and bending of the Body: But in Man by reason of his loftie and vpright frame and composition of Body, the fore-part is alike exposed to outward iniurie as the hinder-part, and therefore it was meet the more noble part should be couered and (as it were) defended with haire. Onely Man hath haire growing vnder the Arme-holes and about the Priuy-members. Man alone growes hoary-haired and bald-headed.

The Legges or Haunches of all foure-footed Beasts, are abundantly full of bones and sinewes, but very scantie of flesh; on the contrarie, Man hath almost no part of his Body more fleshy then his Hipples, Legges and Thighes.

Foure-footed Beasts doe bow both their fore-legges and their hinder-legges contrarie to Man, for he bowes his Armes backe-ward and his Legges fore-ward.

Man, when he is come to his full growth hath his vpper-part lesser then his neather-part; but before he be growne, his vpper-part is the greater; so is it not with the rest of the Creatures; and therefore his manner of going is not at all times alike, but at first in his infancie he creepes on all foure, afterwards by little and little he rayseth vp himselfe, and at length goes vpon his two Feet.

In other Creatures there is no difference of the bones, but they do all appeare perfect, euen from their beginning; but in Children the fore-part of the Head is soft and tender, and long before it be hardned. And whereas all other Creatures come toothed into the World, Man begins not to haue teeth till the seuenth moneth after his birth.

Furthermore, of all Creatures (excepting Birds) that liue vpon the Land, Man alone is two footed, which moued *Plato* to define him, *Animal bipes implume*; which definition *Diogenes* worthily derided, when he flung a Cocke whose feathers he had pluckt off, into the Schoole, and cryed out, *Behold Platons Man*.

22
Man alone
hath a smooth
and slick skin

Aristotle.

Onely Man by the straitnesse of his Legges goes exactly vp right,
Onely Man vseth to sit, both because he cannot stand long, as the bruit Beasts may, which haue foure feet, and besides doe lye vsually to rest themselues prostrate vpon the ground, ; for that two feet cannot long beare the weight of the whole Body : as also because sitting is necessarie for more noble and excellent vses, to wit, for the practising and exercising of Arts and for contemplation.

Onely Man hath a Skin polished, smooth, cleare and verie temperate (other Creatures haue either a shelly or scaly Skin, or altogether hairie or else too soft) because Touching is the ground and foundation of all the Senses; and therefore the more simple and pure the Touching is, the cleerer also and the purer is the Sense, and the Phantasmes or imaginations the more subtile : by meanes whereof, the operation of the Soule, is so much the more loftie and profound. And for this cause, *Aristotle* in his second Booke *De Anima*, is of opinion, that the strength and vigor of the wit and vnderstanding, are to be iudged of by the coursenesse or finenesse of the Touch.

CHAP. V.

How profitable and behouefull Anatomie is to the knowledge of Mans selfe.

He that
knowes him-
selfe, knowes
all things.

Plato in
Alcibiade.
How profit-
able it is to
know our
selues.
Demonax.
Socrates.

Thales.

Anatomie the
most sure guid
to the know-
ledge of our
selues.

Democritus.

Anatomie
teaches how
to order the
state of the
mind.

Seeing then that Man is a Little world, and containes in himselfe the Seeds of all those things which are contained in the most spacious and ample bosome of this whole vniuerse, Starres, Meteors, Mettals, Minerals, Vegetables, Animals & Spirits; whosoever doth well know himselfe, knoweth all things, seeing in himselfe he hath the resemblance and representation of all things. First, he shall know God, because he is fashioned and framed according to his Image, by reason whereof, he is called among the Diuines, *The royall and imperiall Temple of God*; he shall know also the Angels, because he hath vnderstanding as they haue; he shall know the bruit Beasts, because he hath the faculties of sense and appetite common with them; he groweth as the Plants doe, he hath being & existence as stones haue, and in a word, he is the rule and square of all Bodyes.

Wisely therefore did the Oracle of *Apollo*, incite and stirre vp euerie Man to the knowledge of himselfe, as *Plato* hath it in *Alcibiade*. This by the Iudgement and consent of all Men, is true and sound Philosophy. For *Demonax* being asked, *When he began to professe Philosophy*, made answer, *When I began to know my selfe*. *Socrates* held it the next point to furie and madnesse, to enquire into high matters, and to search into strange and vncouth busineses, and be ignorant in the meane while of those things that be in our selues. This preposterous skill was once verie merrily and wittily by an old Wife cast in the teeth of *Thales* the Philosopher of *Miletum*; who as he inconsiderately cast vp his eyes to behold the Heauens, fell into a Pit; the old wife cryed out, *Thou Foole, thou pryest into matters that are aboue thee, and art ignorant of those things that are below thee, nay even within thee*. Surely it was a worthy speech, and not beseeming an old Beldame but a Philosopher. But this same knowledge of a Mans selfe, as it is a very glorious thing, so it is also very hard & difficult. And yet by the dissection of the Body and by Anatomie, we shall easily attaine vnto this knowledge. For seeing the Soule of Man being cast into this prison of the Body, cannot discharge her offices & functions without a corporeall Organ or Instrument of the Body; whosoever will attain vnto the knowledge of the Soule, it is necessarie that he know the frame and composition of the Body. After this manner, *Democritus* of *Abdera*, that he might find out the seat of Anger and Melancholy, cut in peeces the Bodyes of Beasts, and when he was taxed of the Citizens for madnesse in so doing, he was by the censure and determination of *Hippocrates*, adiudged to be verie wise and prudent.

Go too then, Is not he sayd to know himselfe, who can tell how to temper and order the state and condition of his mind, how to appease those ciuill tumults within himselfe, by the stormes and waues whereof he is pittifully tossed, and how to suppress and appease those varieties of passions wherewith as it were with so many Furies he is vexed and tormented? But all this Anatomie doth very plainly teach vs. For he that seeth & obserueth the whole Body, which by the structure and putting together of sundry parts of diuers forts and kinds, is (as it were) manifold and full of varietie, to be made one by the conti-

nuation

uation and ioyning of those parts; he that considereth the admirable sympathy of the parts, their mutuall consent and agreement, their common offices or officiall administrations one for the helpe of another, how they make not any couetous reseruation to themselves, but doe freely communicate each with other; such a Man no doubt will so moderate and order the conditions and affections of his mind, as all things shall accord & ioyn in a mutuall agreement, and the inferiors shall obey the superiors, the passions obey the rule of right reason. He that shall diligently weigh and consider the vse of euerie part, the fashion, scituation and admirable workmanship of them all, as also, the Organs and Instruments of the outward Senses, he shall easily perceiue how and after what manner he is to make vse of euerie part; then which thing, what can be more excellent? What more profitable?

Thou hast an vpright frame and posture of Body, that remembring thy begining, thou shouldst not like the bruit Beasts growell vpon the ground, or dote vpon earthly things, but lift vp thy selfe towards Heauen, and say with the Diuines, *our conuersation is in heauen*. Thy eyes are set in a high place, that thou mightest take notice, they are giuen thee to be aduanced to the contemplation of heavenly things.

Two Eares and those wide open, hath Nature ordained thee; to teach thee that thou must heare, and by hearing, learne twice as much as thou must speake. Nature hath giuen thee but one tongue, tyed with ten Muscles, and reyned with a verie strong ligament, besides, as it were with a Bridle, shut vp and enclosed within the mouth and teeth, as it were within a grate or lattice, that the mind might first discerne and iudge of a thing before it vtter it, and that our words might first passe by the file, before they passe by the tongue. If you looke into the seats and residence of the faculties of the mind, you shall find the Rationall facultie in the highest place, namely, in the Braine, compassed in on euerie side with a Scull; the facultie of Anger, in the Heart; the facultie of Lust or desire, in the Liuer: and therefore we may gather these lower and inferiour faculties, must be seruiceable and obedient to the higher, as to the Queene and Prince of them all. And if both Princes and Peasants would weigh and consider the mutuall offices betweene the principall & the ignoble parts, Princes might vnderstand how to rule, and Peasants how to obey. Princes may learne of the Braine how to make Lawes to gouerne their People; of the Heart, how to preferue the life, health and safetie of their Citizens; of the Liuer, they may learne bountie and liberalitie. For the Braine sitting in the highest place, as it were on a Tribunall, distributeth to euery Organ or Instrument of the Senses, offices of dignity: The Heart like a King maintaineth and cherisheth with his lively and quickning hear, the life of all the parts: The Liuer the fountaine and well-spring of most beneficall humidity or iuyce, nourisheth and feedeth the whole family of the Body, and that at her owne proper cost and charges, like a most bountifull Prince. As for the meaner sort of People, they may easily vnderstand by the ministring and seruile Organs, what be the limits of seruice and subiection. For the parts that are in the lower Belly doe all serue the Liuer; the Stomach doth concoct the meat, the Guts distribute & diuide it, the Veines of the *Mesenterie* prepare it; the Bladder of Gall, the Milt and the Reines, doe purge and cleanse the princely Palace and thrust as it were out of the kitchin, downe the sinke, all the filth and garbage. The parts that are included within the Chest, doe serue the Heart; those that are in the Head, doe attend the Braine, and so each to other doe afford their mutuall seruices. And if any one of them doe at any time faile of their dutie, presently the whole House-hold-gouernment begins to run to ruine and decay.

The euidence of which truth, being by way of *Apologe* or Parable, seasonably represented to the People of *Rome*, by *Menenius Agrippa*, he reuoked them, and laid as it were a Law vpon their furie, when they had gathered themselves into the Mount (which afterwards was thereupon called *Sacer*) hardly brooking the gouernment of the Senate. So that Anatomie is as it were a most certaine and sure guid to the admirable and most excellent knowledge of our selues, that is, of our owne proper Nature. And therefore we read, that valiant and couragious Princes, worthy and renowned Nobles, yea and inuincible Emperors, being moued and enticed with this desire of the knowledge of themselves, did most studiously practise this worke of Anatomie, euen in the noyse and clattering of weapons and armor, and in the verie medly and tumult of warre.

Alexander the Great, among all the maine and great triumphs of his so excellent achievements, gloried that he had diligently obserued vnder his Master *Aristotle*, the nature

sed Anatomy.

and feuerall parts of liuing Creatures. And it is found in the Records and Monuments of ancient Histories, that the Kings of the *Egyptians*, did make dissection of Bodyes with their owne hands. *Marcus Antonius* that great Commander, affirmed that he had learned his owne constitution by the dissection of other Bodyes. We haue also read, that *Boetius* and *Paulus Sergius*, two *Romane* Consuls, were Auditors of *Galen*, when he publickly practised this dissection in the Citie of *Rome*. And so much shall suffice for the first profit and commoditie that we may reape by Anatomie.

CHAP. VI.

How profitable and helpfull Anatomie is to the knowledge of God.

How profitable
Anatomy
is to the know-
ledge of God.

It is no doubt an excellent thing for a Man to attaine to the knowledge of himselfe, which thing Anatomie and dissection of Bodyes doth teach vs, and as it were point out vnto vs with the finger; but there is another farre more diuine and vsefull profit of Anatomie, proper and peculiar to vs to whom the Light of the Gospel hath shined, namely, the knowledge of the Immortal God. That high Father & Creator of all things, who onely by himselfe hath Immortalitie, dwelling in that Light that is clearer then all lights, vnto which there is no access, whom no Man can either see with his eyes, or comprehend with his mind, that eternall Father (I say) cannot be knowne but by his effects; and all the knowledge of God that can be had, must be deriued not *à priori*, but *à posteriori*, not from any cause or matter preceding, but from the effects and things consequent.

Moses.
Paul. ad Rom.

So we read in the sacred Scriptures, that *Moses* could not endure the bright shining face of God, his eyes were so dazled therewith. *The inuisible things of God* (saith the Apostle) *are knowne by those things that are visible*. Who is it therefore, that will not honor, reuerence and admire the Author and Workman of so great a Worke, if he do attentively aduise with himselfe, how wonderfull the Fabricke and structure of Mans body is? *I will prayse thee, O Lord* (saith that kingly Prophet) *because I am wonderfully made*. *Phidias* his *Minerua*, *Apelles* his *Venus*, *Polycletus* his *Rule*, are admired by Antiquitie; and therefore great and high honors haue been decreed vnto them. *Ctesicles* is commended for making a marble Image with such excellent art and cunning, that the *Samian* young men in desire to obtaine the same, were contented to lodge night by night in the Temple. And wilt not thou admire the Archtype and patterne of all these, I meane the Body of Man? They did imitate in the workes of Nature, that which is of least respect and regard, namely, the outward face and feature: for their workes are but dumbe, without motion or life. But by the view of Anatomical dissection, we see & are able to distinguish the variable and diuers motions of Mans body, and those also verie strange and vncouth.

The frame of
Man is Gods
Booke.
Heraclitus.

Some of the ancient Writers, haue dignified the frame of Mans body with the name and title of *The Booke of God*. For indeed, in all Men there appeareth certaine sparkes of a naturall Diuinity, or diuine Nature; as *Heraclitus* witnesseth, who sitting in a Bakers shop and perceiuing some of his Auditors which desired to speake with him, would not come vnto him into so homely a place, *Come in* (saith he) *for euen here there be gods also*. *Iouis omnia plena*, *All things* (saith the Poet) *are full of Iupiter*. For euen in the smallest and most contemptible Creature, there is matter enough of admiration; but yet in the frame of Mans body, there is (I know not what) something more diuine, as wherein appeareth not onely the admirable Power of God, but his Wisdome euen past all beleefe, and his infinite and particular goodnesse and bountie to Man.

Gods admira-
ble power shi-
neth in the
frame of Man

The wisdom
of God in the
workmanship
of the parts.

For his power, it is not onely visible, but palpable also, in that of so small a quantitie of Seed (the parts whereof seeme to be all homogenie or of one kind) and of a few drops of Blood, he hath framed so many and so diuers Particles, aboue 200 Bones, Cartilages yet more, many more Ligaments, a number of Membranes numberlesse, as also the Pipes or Trunkes of the Arteries, millions of Veines, Sinnews more then 30 paire, Muscles almost 400; and to conclude, all the Bowels and inward parts. His incredible Wisdome appeareth in the admirable composition of the whole, made of so many parts, so vnlike one to another. Enter thou whosoever thou art (though thou be an Atheist, and acknowledgedst no God at all) enter I beseech thee, into the sacred Tower of *Pallas*, I meane the Braine

Braine of Man, and behold and admire the Pillars and arched Cloysters of that princely Palace, the huge greatnesse of that stately building, the Pedistals or Bases, the Porches and goodly Frontispice, the foure arched Chambers, the bright and cleere Mirror, the Labyrinthean Mazes and web of the small Arteries, the admirable trainings of the veins, the draining Furrowes and Water-courses, the liuing Ebullitions and springings vp of the Sinnewes, and the wonderfull fecunditie of that white Marrow of the Backe, which the Wise-man in the Booke of the Preacher calleth the Siluer cord. From the Braine, turne the Eye of thy Mind to the Gates of the Sunne and Windowes of the Soule, I meane the Eyes, and there behold the brightnesse of the glittering Cristall, the puritie and neat cleannesse of the watry and glassie humors, the delicate and fine texture of the Iuncles, and the wonderfull and admirable volubilitie of the Muscles, in turning and rowling of the Eyes. Marke and obserue also, the art and curious workmanship appearing in the inward part of the Eare, how exquisitely it is made & trimmed with Labyrinths, windings, little windowes, a sounding Timpane or Timbrill; three small Bones, a Stirrop, an Anuile and a Hammer; the small Muscles, the Nerue or Sinnew of Hearing, and the Cartelaginous or gristle passage, prepared for conueying all sounds vnto the Sense. Looke vpon the vnweariable and agile motions, the conquering power, the frame and composition of the Muscles, the proper and peculiar kind of Flesh, the Membranes, the Veines & Sinnewes, and the Bridle, all easily distinguished within the compasse of that little Body, or rather little member of the Body, the Tongue, wherewith we blesse God, and wherewith we curse Men.

Consider and obserue the Heart, his two Ventracles, Eares as many, foure notable vessels, which, as *Hippocrates* saith, are as it were ποταμοὶ καὶ πηγαὶ φύσεως ἀνθρώπου, the Fountaines and Well-springs of the humane Nature, and the Riuer and sources whereby the whole Body is watered and refreshed; besides, 11 Flood-gates; the admirable and intricate Textures of the vessels of the Liuer, the separation and diuision of the currents of the Arteries and the Veines; and in a word, consider the admirable structure of all the parts, Animall, Vitall and Naturall; wilt thou not cry out, though it be against thy will, O admirable Archite& ! O vnimitable Workman ! And wilt thou not with the inspired Prophet, sing vnto the Creator this Hymne, *I prayse thee (O Lord) because thou hast shewed the greatnesse of thy wisdom in fashioning of my Body?*

Lastly, the infinite goodnesse and bountie of God shineth in this excellent workmanship, for that he hath so well provided for all the parts, that euerie one hath her proper and peculiar vse, and yet all are so fitted and knit together in such an harmonie and agreement, that euerie one is ready to helpe another; and any one of them being ill affected, the rest are immediately drawne to a simpathy and participation with it. Which societie and fellowship of the parts, *Hippocrates* in his Booke *De Alimento* hath thus breefly, but excellently expressed, *συνεπείρα, μία, σύμφορα μία, συμπεθεία πάντα*: *One agreement, one consuence, all consenting.* To conclude then, these wonderfull and euer-worthy to be admired workes of God in the composition and frame of Mans body, are as it were dumbe Schole-masters, the Bookes of vulgar Diuinitie, and the Doctors and Teachers of diuine Wisedome.

The elegant
workmanship
of the whole
frame,

Hippocrates
in his Booke
of the Heart.

Gods infinite
goodnesse in
the structure
of the Body.

CHAP. VII.

How profitable Anatomie is to Philosophers and Poets.

Hese two fruits of Anatomie, as they are abundantly beneficiall and profitable, so they seeme to be common to all in generall; First, the knowledge of our owne nature, and then of the inuisible God. There are also other benefits and commodities of Anatomie proper and peculiar to Philosophers, Poets, Painters, yea, and to the most part of Handy-crafts-men and Artificers, to teach them the better to bring their Arts to perfection. And first, *Galen* doth account Anatomie verie proper to a naturall Philosopher, though it were but only for speculation sake, or otherwise to teach him the singular workmanship of Nature in euerie particular part. For in as much as the proper & proportionable subiect of his Art is a Body naturall, and the Body of Man is as it were the square and rule of all other Bodies, he ought not, nor cannot be truly accounted a naturall Philosopher, who is ignorant of the Historie of

Anatomy

Painters.
Homer.

Mans body; and for this cause; that most excellent *Genius*, and Interpreter of Nature, *Aristotle*, wrot those elegant and exquisite Bookes of the Historie of the Parts, and of the Generation of living Creatures. Anatomie is also verie profitable for a morall Philosopher: For he shall easily learne by the mutuall offices & duties of euerie part, and by the constitution of the naturall Household gouernment appearing in our Bedyes, how to temper and order the manners and conditions of the mind, how to rule and gouerne a Common-wealth or Citie, and how to direct a private House or Family.

Isare to speake how profitable it is for Poets and Painters, for the perfection of their Art and Science; for euen *Homer* himselfe hath written many things, and those verie excellent concerning Anatomie. But my purpose is onely to shew, that for a Physitian, a naturall Philosopher, a Chirurgeon and an Apothecarie, it is not onely profitable, but euen also absolutely necessarie.

CHAP. VIII.

Wherein is demonstrated that Anatomie is not onely profitable, but of absolute necessitie for Physitians and Chirurgions.

Necessarie for
curation
Hippocrates

Anatomy
necessarie for
a Chirurgion

AS Geography is worthily accounted a great euident for the credite of an Historie, so to them that any way appertaine to the art of Physicke, the knowledge of Mans body seemeth to be verie necessarie, *ὅτις τις τὸ κοινὸν ἀρχὴν τῆς ἐπιστήμης*. For the nature of the Body is the first thing to be spoken of in the Art of Physicke. Againe, *Hippocrates* in his Booke *De Flatibus*, maketh but one Idea of all diseases. It is onely the varietie and difference of places, that maketh the difference of diseases. He therefore that will be ignorant of the Historie of the parts of Mans body, he shall ill distinguish and discern the affections of the same, worse cure them, and worst of all fore-tell who are likely to recouer and escape, and who not.

The discerning and iudging of a disease, consisteth in two things, namely, the knowledge of the euill affect, and the knowledge of the part so affected. The signes of the part affected, are drawne and deriued from many Fountaines (as it were) but especially from the scituation, and from the action empaiied. For he that knoweth the action of the stomach to be concoction, if the concoction be impaired, he may easily discern that the stomach is ill affected. He that knoweth the Liuer to be placed on the right side of the paunch, if the right *hypocondrium* or side be sore, or doe swell, he will presently affirme, that the Liuer and not the Spleene is ill affected. Now this scituation, as also the actions of all the parts are taught and demonstrated vnto vs by Anatomie onely.

For *Prognosis* or prediction of the euent of diseases, *Hippocrates* maketh three chiefe and maine heads of it: Those things that are auoyded, the action impaired, and the habite of the Body in the colour, figure, and magnitude or quantitie; all which are discerned onely by Anatomie. Now how much the knowledge of the feuerall parts of the Body auaileth towards the curing of diseases, *Galen* hath verie well expressed in the beginning of his Booke *De Osibus*: *πάντα* (saith he) *ἐν τῇ ἰατρικῇ σκοποῦνται τὰ κατὰ φύσιν*, that is, All things that concerne the action of healing, haue that for their scope or direction which is naturally disposed, or in a good and laudable constitution. *Hippocrates* in his Booke *De officina Medici* giueth this rule That the Physitian should first looke into those things that are alike one to another, and then to those things that are unlike: Insinuating thereby, that he that knowes the perfect Sanitie or health of euerie part, shall easily discern if it fall from that perfection, by the perfection which remaineth in other like parts not tainted. *Aristotle* in his first Booke *De Anima*, vsurpeth a rule of Geometry, That which is straight and right (saith he) doth not onely measure it selfe, but bewrayeth that which is oblique or crooked. In like manner, how shall a Physitian restore or set right bones that are broken or out of ioynt, if he be ignorant of their naturall place, figure & articulation? The exquisite method of healing cannot be performed but by Indications, and Indications are not onely deriued from the disease, but also from the part affected, and the remedies must be changed and altered, according to the diuers and feuerall nature, temperature, scituation, connexion and sence of the part.

Neither is Anatomie needfull onely for the Physitian, but euen also for the Chirurgion and Apothecarie. The knowledge of the outward parts, as the Muscles, the Nerues, the Veines

Veines and Arteries, is most necessarie for a Chyrurgion, for feare lest in his dissections and launcings, he should mistake a broad Ligament for a Membrane, and a round Ligament for a Nerue or Sinnew, lest he should diuide an Arterie in stead of a Veine; for he that is ignorant of these things, shall euermore be in doubt; in things safe and secure, still fearfull; and in things that are to be feared, he will be most secure and audacious.

An Apothecarie also shall find it verie needfull for him to vnderstand the scite and figure of the parts, for the better applying of such remedies as shall be requisite. For he must apply his topicall and locall Medicines, Fomentations, Oyntments or Liniments and Emplaisters, in their apt and proper places; as if the Liuer be ill affected, on the right-side; if the Spleene be ill, on the left-side; if the Wombe or Bladder be diseased, then vpon the *Hypogastrium* or Water-courfe, betweene the Nauell and the Priuy-parts; if the Heart be ill affected, then on the left Brest must the remedies be applyed. He must also make his Plaister or other remedy of the same figure that the part affected is of, least the parts adioyning be couered therewithall.

I forbear to speake how profitable and necessarie it is for the explayning of the writings of *Hippocrates*, *Galen* and all the ancient Physitians. For in them there are many passages darke and obscure, whereunto the knowledge of Anatomy will giue a great light and splendor: And therefore in old time, Physitians were wont to propound vnto their young Schollers the Precepts of Anatomy, as the first Rudiments and Principles of the Art of Physicke and Chirurgerie.

Anatomy profitable for an Apothecarie.

Profitable for they vnderstanding of the writings of the Ancients.

CHAP. IX.

With what method Anatomy may be best taught and demonstrated.

BEeing then, the profite and necessitie of *Anatomy* is such and so great, I would perswade all Students, in our Art especially, and in Chirurgerie, that they would verie heedfully and diligently employ themselves in the study of the same; neither shall they need to be deterred or afrighted with the difficultie, for it is verie easie and feasible, if it be layd downe in a good order and method, otherwise the most easie and obuius Art proues hard and obscure. The method therefore of learning and teaching *Anatomy* is on this manner.

The *Art of Anatomy* (as I suppose) may be attained two wayes; by Inspection, which we call *αὐτοψία*, and by Instruction: And both these wayes are verie necessarie, if the perfection of the Art be desired: But the first is the more certaine, the latter carryeth with it greater grace and state: The former may be called the way of Historie, or the Historicall way; the latter, the way of Science, or the Artificiall way. The first, which is Inspection, is either of Figures depainted or carued, and printed on Tables onely, or of the Bodies themselves of Men or Beasts; of Men, onely when they are dead; of Beasts, both dead and liuing, for the better obseruing of the diuers and obscure motions of the inward parts.

In like manner, the way of Doctrine or Science is double; one, by the writings of most famous and renowned Men; another, by the liuing voyce of a Teacher or Instrueter.

The Inspection of Figures some haue disallowed, because they are bare shadows, which in their opinion doe rather hinder then further young Students. For, if *Galen* would not haue Plants or Hearbes painted or desciphered, no nor so much as described, but taught and deliuered by Hand onely: How would he haue endured the delineation of the parts of our Body?

But I am not altogether of that opinion, to thinke these Pictures vaine and idle, because I see euerie day represented vnto mine eyes by these Pictures many things, & those oftentimes of great consequence, which were vnkowne to the skilfullest Artists of former Ages. Neither doe the Geometricians & Geographers, who are but the Anatomists of the Great world, as we are of the Little; despise those demonstrations which in Cards and Maps they receiue one from another. Againe, it is not alwayes, or in each place easie to find and obtaine such store of humane carkasses, and therefore that want is well supplied by a curious draught or delineation of such obseruations, as are made in true dissections by cunning Artists; that so both the memorie of those that were present may be

Anatomy to be attained two wayes, by Inspection and by Instruction.

Galen disallowed Pictures of Plants and Anatomy.

The benefices of Pictures.

Geometricians are Anatomists of the Great world.

A caution.
Comparison

refricated and refreshed, and such as were absent, made also partakers of their Labours; yet for all this, I doe not thinke it fit to trust too much to these silent shadows. For as it is not possible to make a good Commander, or a skilfull Pilot by any typicall or representatiue Army, Fortification or Water-card, but onely by practise and experience: So it is a verie vaine thing to take in hand to learne Anatomy by the bare inspection of Figures, without practise vpon the Body it selfe: And because our Art concerneth the cure not of Beasts but of Men, we must therefore exercise our selues chiefly in the Anatomy of the Body of Man, and that not alieue but dead.

Who vsed to
butcher men
alieue.

The cutting
vp of men
alieue is not
onely inhu-
mane, but also
of no profit
or vse.
Obiection.

Answer.

I am not ignorant that some of the ancient Physitians, as *Herophilus* and *Erasistratus*, by the License of Princes whom they had possessed with the profit thereof, did anatomize the Bodyes of condemned wretches even whilst they were alieue, which also in our Age hath been done (some say) by *Carpus* and *Vesalius*. But for mine owne part, I hold it a very friuolous and vaine thing, beside the horror and inhumanitie of the fact, which almost no necessitie can sufficiently warrant. For liuing dissections (as we call them) are then put in vse, when we would find out some action or vse of a part which by the dead Carkasse cannot be discerned; now all those we may find as well in Beasts as in Men. If it be objected, that there is some difference betweene the actions of Men & of Beasts, especially the Animall; and that the Organ of voluntarie motion, to wit, the Muscles, are not alike in both kinds. I answer, that for the discerning of actions that belong to motion & sense, there is no need of dissection, for they are almost all of them apparent to the senses; onely the motions of the hidden and secret parts, as not being subiect to sense, must be sought out by dissection. Now of those hidden motions, that of the Heart and Arteries, the Midriffe, the Braine and the Guts, which are of greatest consequence, are all one in Men and in Beasts; wherefore it is not Anatomie but Butcherie, to mangle the trembling members of Mans body, and vnder, I know not, what slender and idle pretence of profite or behoofe, to violate the sacred Law of Nature and of Religion.

The ancient Physitians were not allow'd to cut vp dead Carkasses of Men, as we now vse dissection, but it was held a verie impious and prophane thing: How abominable then is it, and fauouring of *Caniball* barbarisme, because we would make a neerer cut to our vnderstanding by our eyes, then by the discourse and labour of our minds, to gather knowledge by the dissection or rather butcherie of liuing Men, if there were any vse of it, as we haue shewed there is none. Let vs therefore content our selues, and giue due thanks vnto our State, by whose Lawes we are allowed dead Bodyes for dissection, euery yeere a competent number: And if there be any where want of such, we may haue resort to the Bodyes of Beasts, and make dissection of them both alieue & dead; alieue more sparingly, all be it by Anatomy of liuing Bodyes, we may better discern the actions of the parts, and by what Muscles euerie part is moued; in the dissection of dead Bodyes, the situation, figure, magnitude, connexion and originall of the parts, are well enough perceived.

Those Beasts
which come
nearest to the
frame of mans
body, are fit-
test to be dis-
sected.

Five sorts of
Beasts ac-
cording to
Galen

The method
of Anatomy.

Lawes and
rules of
Anatomy.

Let young
beginners first
exercise their
hands in the
externall, for
as much as the
know-
ledge of them
is most easie
and necessarie
for a Chirur-
gion.

Now, because there are many kinds of Beasts, those are to be made choyse of for dissection, which come nearest to Mans body. *Galen* reduceth them to five sorts. The first sort is of such as chew the cud, that is, which after they haue eaten their meat, doe bring it againe from the Dew-lap, as from a kind of stomach, backe vnto the mouth, as Sheep and Oxen. The second sort is of those which diuide not the Hoofe, as Asses, Horses & Mules. The third sort are such as haue teeth in manner of a Saw, as Lyons, Dogges and Wolues. To the fourth sort, he referreth Hogges. To the fifth, Apes. Now the dissection of all, or any of these, whether Man or Beast, is not to be taken in hand confusedly and disorderly, but methodically & with a due course of proceeding, and therefore it shall not be amisse, to prescribe some Lawes and Rules of Anatomy, for the better and more orderly practise and exercise of the same.

This therefore, to begin withall, shall be the most generall and common Rule, that we begin with that which is best knowne, and that the dissection of dead Bodyes goe before that which is of liuing Creatures, because it is more easie and better knowne.

Againe, whereas some parts are externall and outward, others internall and inward: Let young beginners first exercise their hands in the externall, for as much as the knowledge of them is most easie and necessarie for a Chirurion.

Thirdly, whereas of the parts some are spermatieall and solid, as Bones, Gristles and Ligaments; others fleshy, as the Muscles: We must begin with those that are the props

and

and supporters or vpholders of the rest, as the Bones, to which the Muscles doe cleave, from which they spring and arise, and into which they are ingrafted or inserted. And indeed, before *Galens* time, the ancient Physitians in the Schoole of *Alexandria*, did vse to quarter Bodies for their Schollers first, and afterward allow them whole Carcasses. Againe, we must know, that for the exquisite discerning of the solid parts, the Bodies of old and leane Men are the fittest, because they are not so fleshy or so over-growne with fat; to which are answerable the Bodies of such as dye of Consumptions.

Fourthly, whereas there is a two-fold dissection, either of a part taken from the whole, or of a part ioyning to the whole: The dissection is first to be made of a part taken from the whole, because it is more easie then to dissect a part ioyning to the whole.

Fifthly, whereas in euerie particular part *Galen* enioyneth three things to be obserued and respected; the Structure, the Action and the Vse: The Anatomist must first search out the Structure or composition, then the Action, and lastly the Vse.

Lastly, in making dissection, there is a two-fold order to be obserued: The one, where there is store of dead Bodies; the other, where there is want and scarcitie. If there be store of Bodies, you shall in one looke onely to the Vessels, in another to the Muscles, in a third onely to the Bowels or Entrails: But if you haue but one Body and no more, and yet would see all in that, choose a Body that is sound and vntainted, and either hanged, smothered or drowned; and in this Body great skill must be vsed, that euerie part may be shewed in his order and place. Now this order of Anatomy is three-fold; of Dignitie, of Scituation or Dissection, and of Preseruacion or Continuance. The order of Dignitie requireth, that we should begin with the Braine, as with the most noble part. The order of Scituation or Dissection requires, that we should first demonstrate those parts which first appeare in view to the beholders. And for Diurnitie, if we would keepe a Body long, the dissection must be begun at those parts which are most subiect to Corruption: and therefore, first cut vp the lower Belly, then the Chest, after the Head, and lastly the Ioynts. This order all Anatomists doe obserue in Schooles, and in all publike dissections, when as they desire to shew all, or the most part, in one and the same Body: And this is the first method or order of learning Anatomie, namely, by Inspection, which is gayned by Dissection.

Anatomy may also be taught without dissection, and that either *vina voce*, by the liuing voyce of the Teacher, or by writing. For there are many things which cannot be knowne by Inspection alone, which may notwithstanding in good and apt words be taught, and so compassed; as namely, why the Muscles are such and so many, why of such Figure, Magnitude, and the like: And for this cause, the Monuments and Labours of old and new Writers in this kind, must be diligently trauelled in; whose Names I intend to declare in the next Chapter. Now Anatomie may be described and so taught after a two-fold method. The one is called the way of *ἀνάλυσις* or resolution, which resolueth the whole into his parts; as when we diuide the Body of Man into foure principall parts, the Head, the Chest, the Belly and the Ioynts; and these againe we sub-diuide and mince smaller and smaller, till we come to the most simple, ynmixt and uncompounded parts. The other is called *σύνθεσις*, or the way of composition, which of similar parts maketh dissimilar, and of these compoundeth the whole frame and structure. But we esteeme this last not to be the way of *Art*, but of *Nature*; and therefore leave it to her who is onely able to performe it. The former belongeth vnto vs, as being the way of Art, for we intend not to make a new Man, but to preserue and keepe a Man already framed and made: And therefore as he that commeth to an old yet stately Palace which he is not able to imitate, to repaire and amend the same, doth first take off the coverings, that so he may looke into euerie corner and see the defects of it, that he may apply himselfe better to the reparation: So we will first remoue the couer and shrine of this sacred Palace, & after looke as narrowly as we can, into the secret corners of the same, that when we are called, we may be better able to set our hands to the worke: And yet after we haue ended our whole discourse, we will also giue you a view (as well as we may) of the worke of Nature, iterating the Figures and their explications which are disperfed through the whole worke, but much more largely, according to the order of *σύνθεσις* or composition, that nothing may be wanting vnto you, which either our industry or charge may accomplish for our behoofe; but first we will insist in order of Dissection.

description of
the Back-bone

Hippocrates of Coos was reuerenced by Antiquitie as the Oracle of Greece, or a kind of Deitie, rather to be adored then admired, much lesse imitated. This Man, when the Art of Physicke was yet rude and vnpolisht, so labored vpon it, that he left it smooth and terce: The knotted bud, by the strength of his wit and vigorous rayes thereof, he made to spread into a glorious flower. He like a good Husband, hath reduced the seeds of Physicke, dispersed before in the large Field of the World, into certaine Seed-plots, whence we may fetch them one by one at our pleasure: And truth to say, his writings resemble seed most of all, for they are not great, but full of power and efficacie: For as a small Acorne hath in it the power of a mightie Oake, so in him one short Aphorisme consisting of a few words, hath growne to fill whole Volumes of Commentaries; and so all other his writings are verie enigmaticall, hauing in them as many sentences as words. Before Hippocrates time, the knowledge of Anatomie was verie geason and scarce: No writings of the Ancients were extant of that subiect. He was the first Man, that being inspired (as I verily thinke) with a diuine Spirit, and trusting (as well he might) to the strength of the pinions of his owne wit, cut the first way through this Abyffe; not onely leauing encouragement vnto others, but also monuments of many things which pertained to Anatomy. For I verily thinke, that that happy Spirit of Hippocrates, was ignorant almost of nothing that doth necessarily appertaine to the vse and practise of the Art of Physicke. For whereas Galen in his second Booke *De Anatomicis Administrationibus*, maketh two sorts of Anatomy; the one profitable, because it is necessarie for the practise of Physicke; the other, beyond the vse of Art, and more for ornament and pleasure, then profit which he calleth *Superabundant*: I presume I can demonstrate vnto you, that Hippocrates hath most exquisitely and elegantly described that former profitable and vsfull kind of Anatomy.

Of parts some are Similar, some Dissimilar; Similar, are the Bones, Cartilages, Ligaments, Membranes, Veines, Arteries, Nerues; and of all these Hippocrates hath written many things, and those excellently well. Concerning the Bones first in generall, what is their Nature, their manner of Generation, their materiall Cause, their Efficient, and finally, their Vse, he hath excellently demonstrated in his Bookes *De Natura Ossium*, *De Carnibus*, and *De Natura Pueri*. The matter he describeth in these words; *When the Fat exceedeth the Glue, then are the Bones framed*. The efficient cause hath he thus set downe, *τα ὅσα σκληρύνεται ὑπὸ τῆς θερμότητος τοῦ πυρρῶς*, that is, *The Bones being thickned by heat, are exiccated or dried*. The common vse of the Bones, who did euer so accurately expresse in so few words, *τα ὅσα τὰ σώματι στήναι καὶ ὀρθοῦν καὶ εἶδος παρέχονται*, that is, *The Bones doe giue vnto the Body, stabilitie, vprightnesse, and forme or fashion*. He hath also described the particular Historie of the Bones, their seuerall differences, their fashions and their parts. Of the Bones of the Head, he writeth in his Booke *De Vulneribus Capitis*. Of the rest in his Bookes *De Articulis* and *De Ossium Natura*. For before he doe deliuer the diseases or affects incident to the Bones, he enquireth into the nature and fashion of euerie Bone: A tast of which his elegant order, I will giue you in the description of the Back-bone, whereby you may imagine how he hath done all the rest.

The nature of the Back-bone (saith he) *is first to be knowne*. The Figure of it is *θυσκοῦς*, that is, *in some sort right and straight*, but yet so, that sometimes it bendeth outward, sometimes inward. From the first Rack-bone or *Vertebra* of the Neck, to the seuenth, it hath *Figuram λοφῶν*, that is, *Inclining inward*, that it might be substrated or couched vnder the Gullet and the rough Arterie. From the first Spondill of the Backe, vnto the twelfth, it hath *Figuram κωφῶν*, that is, *A forme bunching outward*, that the Organs of respiration might haue the better roome, and a more spacious cauitie to extend themselves in, to wit, the Heart and the Lungs.

The Loynes bend inward, and the *Os Sacrum* or Holy-bone, protuberateth or swelleth outward, yet with a straightnesse too, that so the cauitie of the *Hypogastrium* or Water-course might be the larger, which was to containe the Bladder, the right Gut and the Wombe. The rest of the Bones he pursueth after the same manner.

Concerning

Concerning the Cartilages, Ligaments and Membranes, some things he hath deliuered here and there, but scatteringly. Of the Veines he hath written many things, but all of them verie obscure, in his Booke *De Locis in Homine*, *De Morbo Sacro*, *De Ossium Natura*, and in the second *Ensisquid*. And first, he doth verie elegantly describe the ascendent and descendent Trunke of the hollow Veine, which he calleth *ηρσιν*, that is, *The Liuer-veine*; in the fourth Section of the second Booke *Epidem*. *The Liuer-veine* (saith he) *passeth downward through the Loynes, to the great or Holy bone*. Again, *Arising upwards out of the Liuer, it ascendeth through the Midriffe, and so runneth to the Throat*. As for the particular Historie of the Veines, that is to say, the diuification of their Branches; albeit he hath not precisely set them downe, yet it seemeth he was not ignorant of them, so farre as was needfull for the practise of Physicke: For he mentioneth all those Branches which Physicians vse to diuide in Phlebotomy; as for example, the Veines of the Fore-head, the Nowle or back-part of the Head called *Vena puppis*, and we may call it the Sterne-veine, the Veines of the Tongue, the Eares, the Iugular or Throat-veines, the Shoulder-veine, called *Humeraria*, the Liuer-veine, called *Basilica*, that of the Ham, called *Vena poplitia*, and the Ankle-veines, called *Malleoli*. In the 68 Aphorisme of the first Section, *when the back-part of the Head is pained, the right Veine of the Fore-head being opened giueth ease*.

In his third Booke *De Morbis*, in the *Angica* or *Squinancy*, he striketh the Veines vnder the Tongue. In his Booke *De Aere, Locis & Aquis*, he mentioneth the Veines behind the Eares, which the *Scythians* did vse to open, to helpe the *Scyatica* or Hip-gout. The Iugular Veines, he describeth in the fourth Booke *De Morbis*. In his Booke *De Natura Ossium*, he commandeth to open the Veines of the Hams and Ankles, in paines of the Loynes and Testicles. In the first Section of the sixth Booke *Epidemion*, in fits of the Stone, or inflammations of the Kidneys, he openeth the Ham-veines. The Shoulder-veine he describeth in his Booke *De Ossium Natura*, calling it *Sanguifusus* or the Blood-flowing-veine. In his Booke *De victus ratione in morbis acutis*, in the Plurisie he openeth the *Basilica* or Liuer-veine, which he calleth *την εσω ολβη*, that is, *the inner or internal Veine*. Now the common originall and vse of the Veines, he declareth in his Booke *De Alimento*, as also of the Arteries, *εξωσις φλεβων ηπαρ, ελξωσις αρτηριων καρδιαν*, that is, *the radication or root of the Veines is the Liuer, of the Arteries the Heart*: Out of these, Blood, Spirits and Heat are distributed into the whole Body. Of the Nerues you shall read many things, yet dispersedly: But for their common originall (which all Men were ignorant of) he pointed it out manifestly. All Men almost doe hold, that the softest Nerues or Nerues of Sense, doe arise from the Braine, the hard and such as serue for motion, from the *Cerebellum* or little Braine: But now it is resolved, especially since *Varolius* his curious search by a new manner of Anatomizing the Head, that all the Nerues, euen the *Opticks* themselves, doe arise from this *Cerebellum* or backward Braine, which me thinks *Hippocrates* insinuateth in his Booke *De Ossium Natura*. *Νευρων εκευσις* (saith he) *απο τεινς αρχης παρ εδχιν εστ*, *The originall of the Nerues, is from the Occipitium or hinder part of the Head, euen to the Rack-bones, the Hips, the Priuities, the Thighes, the Armes, the Legges and the Feet*. Of Glandules or Kernels, he wrot an entire Booke. And so much of the Similar parts.

Of the Organicall parts also he wrot much, and that excellently. Of the Heart a Golden Booke, wherein he so excelleth, that I thinke neither *Galen* nor *Vesalius* haue gone beyond him for exact description; but in it there are many things obscure, which needs an Interpreter, if the World were so happy. The Historie of the Infant, the Principles of Generation, the Conceiuing, Forming, Nourishment, Life, Motion and Birth, hath he most excellently described in his Bookes *De Natura Pueri*, *De Septimestri* and *De Octimestri Partu*. We conclude therefore, that *Hippocrates* wrot verie diuinely of Anatomy, but withall so obscurely, as his Workes euen to this Age, seeme to be sealed from the greatest wits. I thinke therefore that he shall merit most of Physicke, who hauing all his furniture about him, shall labour to make manifest to the World, those diuine Oracles, which hitherto we haue rather admired then vnderstood.

CHAP. XI.

What GALEN hath written of Anatomy, and how uniuersally he is accused by the latter writers, especially by VESALIUS.

The prayse of
Galen

Three things
accomplishing
an Anatomist

Almost all the Grecians, Arabians and Latines, doe verie much extoll *Galen*, as after *Hippocrates*, the second Father of Physicke; for as much as he hath in such sort amplyfied and adorned the whole Art by his deepe and diuine Writings, that vnder him it may seeme to be as it were borne anew. For indeed, how be it there were extant before many excellent Monuments and Records, yet were they so confused and shuffled out of order, that it seemed a new worke to gather together those things that were disperfed, to illustrate that which was hard and difficile, rude and vnpolisht; to distinguish and order that which was confused, beside many things which he obserued in his owne particular experience. For other parts of Physicke I will say nothing, but for Anatomy I will confidently auouch, that *Galen* hath so beautified and accomplished it, that he hath not onely disperfed the blacke clouds of ignorance which hung ouer the former Ages, but also giuen great light and splendor to the insuing Posteritie. For whereas there are three meanes, which lead vs as it were by the hand to the perfect and exact knowledge of Anatomy, namely, Dissection of the parts, their actions and their vses: He hath so accurately described them all, as he hath gotten the prize from all Men, not onely before him, but even after him also. The manner of Dissection, he hath manifested in his Bookes, *De Anatomicis Administrationibus*, *De Dissectione Musculorum & Nervorum*.

The actions of the seuerall parts, he hath elegantly described to the life in his Booke *De Naturalibus Facultatibus* and *De Placitis Hippocratis & Platonis*. But aboue all, are those 17 golden Bookes of the *Vse of Parts*, which are truly called Diuine labours and Hymnes sung in prayse of the Creator. So that the benefits we all, and those before vs haue receiued by *Galen*, are indeed verie great: And yet (the more the pittie) almost all the new Writers, doe continually carpe and barke at him, yea teare and rend him, whether it be by right or wrong, wounding and launcing his credit vpon euerie slight occasion: One by way of cauill, another ambitiously seeking to make himselfe esteemed by *Galen's* disgrace, and few with any desire that truth should take place. But as Floods beating against the Rockes, by how much they rush with greater violence, by so much they are more broken and driuen backe into the Maine; so, and such are their bootlesse and ridiculous endeauors, who enterprize by the disgrace of another, especially of their Masters and Teachers, to gaine reputation vnto themselues.

The slander
of the new
Writers
against
Galen

The confuta-
tion of the
first slander.

But let vs see wherein these Nouices doe blame *Galen*. First they say, he hath giuen vs onely the Anatomy of brut Beasts, and not of Man, hauing neuer dissected a Mans body. Again they vrge, that he was ignorant of many things, which at this day are generally and commonly knowne. Thirdly they say, he deliueres many things repugnant and contrarie to himselfe. Lastly, that he hath written all things confusedly & without method or order. For (say they) what method can there be obserued in his Bookes of the *Vse of Parts*, which you call Diuine? First, he treats of the Hand, then of the Legges and Feet, and last of all of the lower Belly and the naturall parts. How silly these calumniationes are, and how miserably these Men are by their owne ignorance deceiued, let all Men heare and iudge. For to begin with the first, I say and affirme, that *Galen* did not onely cut vp the Bodies of Apes, but many times also the Carcasses of Men. My witnesse shall be the Author himselfe. In his 13 Booke *De Vsu Partium*, I am determined (saith he) to set forth the structure and composition of Man alone. In his first Booke *De Anatomicis Administrationibus*, it is meet to obserue and looke into euerie Particula, especially in Men. In the second Booke, Now (saith he) the Foot of an Ape differeth from the Foot of a Man, in that the structure of the Fingers is not alike in them both. In his fourth Booke *De Anatomicis Administrationibus*, and in the third *De Vsu Partium*, he sheweth the difference of the Tendons which goe to the Legges and Feet: And in his first Booke *De Anatomicis Administrationibus*, he saith, that the head of the Thigh is more crooked in Men then in Apes, and the Muscles also vnlike, which are inserted into the Legges. He sheweth also the dissimilitude betweene the Loynes of a Man and an Ape. In his second Booke *De Ratione Vetus*, he saith, that a Man differeth from some Creatures in the

the originall of the Veine called *Azugas*, that is, the solitarie veine, or without a peere. In the 13 Booke *De Vsu Partium*, he saith, That the wombe of a woman, differeth much from that of other Creatures.

So then, if *Galen* did so well vnderstand wherein the Bodyes of Men and Apes did agree, and wherein they did disagree, it is verie likely that he had made dissection of Mens bodyes: for in things which are so like, it is the part onely of an Artist and expert Practitioner, to know and discern what is differing and vnlike. And so much for satisfaction to the first imputation which is iniuriously cast vpon *Galen* by his slanderous detractors. They say farther, that *Galen* was ignorant of many things which appertaine to the structure and composition of Mans body; as if it were not proper to Man to be ignorant. Was not *Vesalius* ignorant of a number of things which were afterward obserued and seene into by *Fallopins*? And doe we not daily find out many things whereof the former Ages were vtterly ignorant? I appeale to that of the ancient Poet, *ἄνθρωπος πάντῃ ὀπῶν*, One Man seeth not all things.

And whereas they object, that *Galen* doth not agree with himselfe, but writeth many things repugnant and quite contrarie, let them learne and be aduertised, that it was the manner of the Ancients, to deliuer many things diuers times according to the opinion of other Men: And the Interpreters beare record, that *Hippocrates*, *Aristotle* and *Plato*, did many times speake after the manner of the common people. So *Galen* speaking according to the opinion of others, may haply write some things that doe not so well agree together: But when he disputed precisely of the point of Anatomie, then he alwayes agreeth and accordeth with himselfe.

Lastly, they clamor that his Bookes *De Vsu Partium*, are written confusedly and without method: But their heat & furie of gain-saying, transports them I know not whither: For the method of these Books is admirable, which being to many heretofore vnkowne, I will now make plaine and bring to light.

I am determined (saith *Galen*) to declare the structure and composition of Man, and the vse of all his particular parts; and therefore what he hath proper and peculiar therein, and wherein he differeth from other Creatures, must first be opened.

First therefore, for the nakednesse of his Soule, he hath Reason, which is an Art before all Arts, and in recompence of the nakednesse of his Body, he hath the Hand, an Organ before all Organs. Of the Hand therefore which Man alone hath, and no other Creature beside, he disputeth in his first and second Bookes, so accurately and elegantly, that he hath preuented all Men for getting any honor by treating of that subiect. And, because the Legges haue a great affinitie with the Hands, and that there is some thing proper and peculiar in the frame and structure of the same, (for onely Man by the benefit of his Legges, goes directly vpright) therefore in his third Booke, he intreateth of the Legges; for so the order of teaching seemeth to require, that those things which are alike, should be deliuered together.

Having declared what things they are which are proper to Man onely, he commeth then to such as are common vnto Man with other Creatures. And whereas of those parts whereof the Bodyes as well of Men as of other perfect Creatures are composed, some doe preserue and maintaine either a particular and indiuiduall Creature, or the generall species or kind; others doe seruice and administer vnto the former, as the Veines, Arteries and Nerues: In the first place, he disputeth of those that concerne the *indiuiduum* or particular Creature: And these are either Naturall, or Vitall, or Animall; by reason whereof, the Body is diuided into three Regions. Of the Naturall parts, he disputeth in the fourth and fifth Bookes; Of the Vitall, in the sixth and seuenth; Of the Animall, to wit, the Braine, in the eighth and ninth: Of those things which depend vpon the Braine, that is, of the Instruments or Organs of the Senses, in the tenth, eleuenth, twelfth and thirteenth Bookes; which may be called the order of Nature. The Organs ordained for generation or propagation of the species or kinds, as well in Men as Women, are described in the fourteenth and fifteenth Bookes. Those parts that are seruiceable to all these, as the Veines, Arteries and the Nerues, are delineated in the sixteenth. The seuenteenth, which is the last, serueth as an Epilogue or conclusion to all the rest: And therefore, these slanderous accusers of so worthy a Writer, are no better worth, then to be sent packing from all societie of ingenuous learned Men.

The confutation of the second slander.

CHAP. XII.

How farre ARISTOTLES skill stretched in Anatomie.

The praise of
Aristotle.Aristotle was
ignorant in
the particular
Historie of
the Creature
and in Dissec-
tion.

Aristotle is intituled by all Philosophers, the true Interpreter of Nature, the Light, the *Genius*, the onely spirit of truth, who is able not onely to stirre vp and awaken Mens minds, but to fulfill and satisfie them. In a word, he is another Nature, furnished with eloquence. For he hath verie curiously determined of all naturall things and their causes; but that so darkely and obscurely, that he is vnderstood but by few; for he was vnwilling to blab abroad and prophane the Mysteries of Philosophy amongst the rude multitude; and therefore he hid them, not vnder a veile of Fables, as the ancient Poets; nor vnder a superstitious proportion of numbers, as the *Pythagoreans*, but wrapped them vp in obscure breuitie; so sending them abroad, as if he had kept them at home. So the Cuttle-fish to deceiue the Fisher-men, poureth forth a blacke humor, and in that cloud she escapeth. And whereas there are two parts of naturall Philosophy; the first concerning the generall and vniuersall nature of things, the latter which searcheth out the particular nature of Man and all liuing Creatures: In the first, *Aristotle* was so absolutely excellent, as no Man, no, nor any age of Men may stand in competition with him; but in the second, how many things he knew not, how absurdly he vnderstood diuers things he knew, *Galen* and all the whole Schoole of Physicians haue proved by demonstrations, but especially by *αὐτοψία*, or the sight of the eye, which is of all arguments the most demonstratiue. He writ Bookes of the Generation, of the Parts and of the Historie of the Creatures, but he bequeathed vs many things out of the Testaments of other Men: Neither is it likely, that he did euer cut vp the Body of a Man; for if he had, he would not haue so foully erred in that which is obuius to the fence. For both in the Historie of the similar parts, and in the description of the dissimilar, he hath set downe many things verie grosse and absurd; as in that, where he writeth, that the Veines doe originally proceed from the Heart, which also he maketh the well-spring of the Nerues; where he saith there are three Ventricles in the Heart; that the Braine was made onely to refrigerate or coole the Heart, and such like many more, which we shall meet withall in our treatings of the Bones, the Veines, the Arteries, the Nerues, the Heart, the Braine, and other particular parts; and therefore in those places, the diligent and studious Reader may looke for, and find them.

CHAP. XIII.

What the other Greeke Authors haue written of Anatomie.

Alcmaus.
Diocles.
Lycus.
Galen.Quintus.
Marinus.
Erasistratus.
Herophilus.Pelops, Galens
Scholemaster.
Diog. Anoll. n.
Asclepiades.
Endemus.
Praxagoras.
Philotimus.
Elianus.
Polybius.
Calistus.

There were after *Hippocrates* time, certaine famous Men, that did diligently practise the Art of Anatomie, and diluiered many things in writing, which haue all perished, I know not by what mishap or destinie, whether I should call it. *Alcmaus Crotoniata* (as *Calebidius* reporteth) did vse to Anatomize Mens bodies. *Diocles Carystus* in his Epistle to King *Antigonus*, diuideth the Body of Man into the Head, the Chest, the Belly and the Bladder. *Lycus Macedo* was accounted cunning in the dissection of the Muscles; and his Bookes (as saith *Galen* in his fourth Booke *De Anat. Administ.*) were with great commendation dispersed all abroad. *Quintus*, *Lycus* his Schoolemaster, wrot some things of Anatomy. *Marinus* published 20 Bookes of those things which *Lycus* was ignorant of in Anatomy. *Erasistratus* did much in this kind also. *Herophilus* (as *Tertulian* saith) cut vp aboue 70 Bodies, and oftentimes the Bodies of liuing Men. Of him *Galen* writeth thus: *Herophilus as well in all other things that appertaine to our Art, as also in Anatomy, did attaine to a most exact and exquisit skill and knowledge, and for the most part made his experiments not in bruit Beasts, as most Men vse to doe, but euen in the Bodies of Men.*

Pelops did publicly teach Anatomy, and was the Schoolemaster of *Galen*, he affirmed, that all the Vessels of the Body, did originally arise from the Braine. *Diogenes Apollonata*, wrot a Booke of Veines. *Asclepiades*, *Endemus*, *Praxagoras*, *Philotimus*, *Elianus*, *Polybius*, *Calistus*, in their seuerall times, did all of them excell in this Art. Yet none of their

writings

writings remaine with vs; but if we beleuee *Aristotle* and *Galen*, they had many foolish and ridiculous conceits. There haue beene also *Greekes* of latter times, who haue done somewhat in Anatomie, as *Aretaeus*, *Theophilus*, *Oribasius*; but *Galen* hath won the Girland from them all, as we haue already proued.

Aretaeus.
Theophilus.
Oribasius.

CHAP. XIII.

Who haue beene the chiefe Authors of Anatomy in our owne times.

Any things also haue the *Arabians* written of the matter of Anatomy, of whom *Auicenna* is worthily accounted, especially for the speculative part, the Prince and Chieftaine; but amongst all, the *Latines* haue taken most paines in this Argument, and amongst them, those of our owne Age; so that now the Art is so beautified,

Auicenna.
Latine
Writers.

that it seemeth the last hand is put vnto it, and the Art of Anatomy may now be accounted to haue attained the verie height of her glorie. Among the ancientest of them, we haue *Mundinus*, who wrot verie perspicuously by way of *apud* or resolution, following the order of dissection. *Carpus* wrot large Commentaries vpon him; but we must needs take them both with many idle and absurd passages, besides the lameness and imperfection of their workes. *Thomas de Zerbis* set forth a large worke, but we imagine that he tooke much from other Men, and had little of his owne, neither had he as we suppose, any great practise himselfe in Dissection. After these came *Vassius*, *Carolus Stephanus*, *Andernacus*. At length appeared *Andreas Vesalius*, who wrot verie accurately; and some thinke, he balked nothing that may appertaine either to Dissection, or to the actions or vse of the parts; but he is condemned of many, and haply not vnworthily; for that hauing transcribed almost all his workes out of *Galen*, yet he cannot afford him scarce a good word, but either pricked by Ambition, or with an itching desire to contradict so great an Authour, he neuer leaues goading and wounding his reputation, and that verie often vnderstandedly.

Vesalius.
an accurate
Writer.

Iacobus Sylvius herein hath carryed away the reputation, that he hath digested in a most exquisite order, the vast and wild Forrest as it were, and confusion of all the Muscles and Vessels, and giuen them particular and proper names, but he was little beholding to his Printer, who hath let slip many escapes, and by your leave added (as we thinke) some things to him verie superfluous. These two, *Vesalius* and *Sylvius* flourished both in one time; but *Vesalius* was too tart and sharpe in his calumniationes; *Sylvius* too obstinate a defender of *Galen*. *Vesalius* hath rashly and vnadvisedly written many things against *Galen*, *Sylvius* in defending his Master *Galen*, is enforced to maintaine many vncouth Paradoxes. *Gabriel Fallopius* the most subtile and acute Anatomist of this Age, hath deserved exceeding much of vs all; for in his obseruations he hath opened many things altogether vnkowne to the former Ages: He wrot also an excellent Commentarie vpon *Galen's* Booke *De Ossibus*. *Columbus* couched the whole Art verie succinctly in 15 Bookes, and penned them verie neatly. *Valuerda* the Spaniard hath done also exceeding well, and with great commendations. *Eustachius* hath published some small workes of Anatomy concerning the Bones, and the frame and composition of the Kidneys. *Baehnius* first exceeded all Men, and since in a later worke, hath exceeded himselfe, both in his Descriptions, and in his Tables. *Archangelus Picholomineus* a Citizen of Rome, hath set forth verie learned Readings of Anatomy, interlaced with many disputations concerning things controuerted. *Varolius*, *Arantius* and *Pigafeta* haue added also their Tribute vnto this Treasure. *Volcherus Coeitur* and *Felix Platerus* haue beautified it with their Tables: *Volcherus* is more easie and facile: *Platerus* is accurate, but not fit Lettuce for euery Mans lips, he must pick nicely that will gather a Sallet out of him, he is so intricate and full of his Dicotomies. Many Frenchmen haue written well in their owne Language. *Iacobus Guillemaeus* the Kings Chyrurgion, hath adorned the whole Art with Tables and Figures, by which he hath made an easie entrance for all Men to vnderstand the grauest Authors. The like may be said of that industrious *Paracelsus*, and *Cabrolus* the Kings Anatomist in *Mompelier*. *Seuerinus Pinus* hath taken great paines: He wrot a Booke of the notes of Virginitie, wherein he hath verie curiously described the parts belonging to Generation.

Laurentius.
his commen-
dation.

Andreas Laurentius hath taken worthy paines, and sweat much in this Sand, to his great honor, and the generall good of the whole Schoole of Anatomists; for beside his descriptions, he hath handled learnedly the Controuersies of euery part, with great euidence of

D

argument,

Bauhine
diligence

Pauus

Iul. Casserius

Argument, wherein I beleue he hath satisfied himselfe and all the world beside. These his Controuersies we haue taken into our worke, yet not alwaies tying our selues to sweare what he sayes, but for the most part we find him in the right. His Descriptions we take vnder correction, not to be so perfect, and his Figures most imperfect. In those two *Bauhine* hath farre exceeded him and all Men else; to whom therefore we sticke the closer, although we could haue wished that *Bauhine* had had the care of his own Worke himselfe, and had not betruusted others with his credite, who haue in no few things fayled his expectation & ours. *Pauus* of *Leiden* is a great Anatomist but writes for his Inscription, *Posse & nolle nobile*. Surely he can doe much, & I would to God he could be ouercome, to communicate himselfe; some things we haue gathered from his own mouth, whereof it shall neuer repent vs. Finally, within these three or foure yeeres, *Iulius Casserius* the Anatomist of *Padua* in *Italy*, set forth an elegant Booke of the five Senses, wherein he hath laboured sufficiently, if not too much; for there is a kind of sobrietie to be vsed also in humane studies, beyond which to be wise, is not farre from folly. *Casserius* hath done many things excellently well, and of good vse, but his extraordinary diligence about the Organs of the Senses in so many Creatures, I see no cause to imitate; for sure I am, by that little experience I haue, that many of these nice & fine points, though they make a faire shew, and tickle the Eares of a Man when he reads them, and delight his Eye when he sees the resemblances of them printed before him; yet when he shall come to search for them in the Body of Man, they will not be so obuius, if they be at all; or if they be found, yet serue rather for a speculative pleasure and admiration, then be of any vse in the Art of Physicke or Chirurgie.

Among our selues *Gemini* was the first: In his Descriptions too brieue, in his Tables too confused, rather contenting himselfe with *Vesalius*, then giuing contentment vnto others: Yet for those times he is worthily to be commended. That good and ingenuous old Man *Banister*, was a true Patriot, he loued his Countrey and Learning, and spent himselfe in doing good, and his memorie is worthy to be registred euen for his Anatomy among the rest of his Labours. At this day we haue also some worthy to be named, who if they listed, could turne the gaze of the World West-ward, and time I hope will bring their Monuments to light. In the meane time, we haue aduentured to hold vp this Taper, at which if they please they may light their Torches.

of Anatomy.
Galen.What things
are required
in artificiall
Dissection.

ANATOMY is a Greeke word, and signifieth Section or Cutting. Hence comes *ἀνατομή*, a diligent and curious Section, vnderaken to get knowledge or skill by. For *ἀνατομή* is to cut with great diligence. Now there is amongst Physitians, a double acceptation or Anatomy; either it signifieth the action which is done with the Hand, or the habite of the Mind, that is, the most perfect action of the Intellect. The first is called Practicall Anatomie, the later Theoricall or Contemplatiue: The first is gained by experience, the second by reason & discourse: The first we attaine onely by Section and Inspection, the second by the liuing voice of a Teacher, or by their learned writings: The first we call Historical Anatomy, the second Scientificall: The first is altogether necessarie for the practise of Anatomy, the second is onely profitable; but yet this profite is oftentimes more beneficiall then the vse it selfe of Anatomy: The first looketh into the structure of the parts, the second into the causes of the structure, and the actions and vses there-from proceeding. According to the first signification we may define Anatomy thus: *An Artificiall Section of the outward and inward parts.* I call it *Artificiall*, to distinguish it from that which is rash & at aduenture, which *Galen* calleth *Vulnerarie Dissection*. For often-times in great wounds we obserue the Figure, Scituation, Magnitude & Structure of the outward and inward Parts; but that obseruation is but confused, for we cannot distinctly perceiue the branchings of the Nerues, the Serpentine and writhen Meanders of the Veines, nor the infinite diuarcations of the Arteries. Now that a Dissection may be made artificially, it is first requisite that the parts be so separated one from another, that they may all be preserued whole, not rent and torne asunder. Next, that those which grow not together, be gently diuided. Thirdly, that those which do grow together, be carefully separated. Fourthly, that we mistake not many parts ioyned together for one, nor yet make many parts of one. Now

Now this Section cannot artificially be accomplished, vnlesse the Ministers haue convenient Instruments, as are these; Razors of all sorts, great, small, meane, sharpe, blunt, straight, crooked and edged on both sides; Sheares or Sizers; round and long Probes of Brasse, Siluer, Lead; a Knife of Box or of Iuory; Pincers of all sorts; Hookes; Needles bent rather then straight; Reeds, Quils, Glasse-trunkes or hollow Bugles to blow vp the parts; Threds and Strings; Sawes, Bodkins, Augers, Mallets, Wimbles or Trepan, Basons and Sponges: The Figures of all which we haue here-vnder delineated, together with a Table whereon to lay the Dead, or bind the liuing Anatomy, with the Rings, Chaines, Cords and Perforations fit for that purpose.

The Instru-
ments of the
Anatomy

If Anatomy be taken in the latter signification, it is defined *A Science or Art, which searcheth out the Nature of euery part, and the causes of the same Nature.* I call it a *Science*, because it hath vniuersall or generall Theoremes or Maximes, and common Notions, out of which, being the *first, true, immediate and best knowne*, all demonstrations are framed. Vnder the name of *Nature*, I comprehend many things: The Substance, which is the habitation of the particular Facultie; The Temper, which is called the forme of the similar part; Those things which follow the Temper, as the Qualities, such as may be felt, hardnesse, softnesse, thightnesse or fastnesse, and raritie; thicknesse, thinnesse, saours or taits, and colors. Appurtinances also or Accidents, as the composition of the part, to which I referre the Magnitude, Number, Position, Figure, Continuitie and Scituation; and finally, the actions of the parts, and their vses.

Another

Anatomy.

CHAP. XVI.

what is the Subiect or immediate obiect of Anatomy, to wit, a Part, where the definition of a Part is unfolded.

THE Subiect of both kinds of Anatomy as well Historicall as Scientificall is a Part. For the Anatomist doth not handle a whole Body, but a Body diuided into Members and Parts; and therefore we must find out what is the nature of a Part and the differences of the same. A Particle, a Member, a Place, *μερος, μέρη, τόπος, μέρος*, signify

The names of
a Part.

Aristotle.

Theodorus.

The definition
of a part.Fernelius
his perfect

a Part.Connexion is
double,
Mathematical
and Physicall

signifie one and the same thing. *Aristotle* thought that the appellation of a Part did best agree to the similar particles, and of a Member to the Organically, and especially to those which were most compounded. *Theodorus* saith that the name of a Part or place hath a larger extent then that of a Member, because that onely is a Member which is organically, but all compound and simple particles are truly called Parts. We with *Hippocrates* and *Galen* make no difference betweene a Part, a Particle or a Place. *Galen* in the first Booke of his Method, defineth a Part to be *whatsoever doth integrate or accomplish the whole*. And in his first Booke *De Elementis*, *whatsoever maketh to the constitution or frame of Mans body*. For a Part is one of those things which the Logicians do call *τὰ μέρη*, that is, *have reference or respect vnto another*: So a Part is said to be a part of the *Integrum* and whole. In his first Booke *De Vsu Partium*, he defineth a Part more accurately thus, *It is a Body which neither is encompassed with a proper circumscription, nor yet is on euery side ioyned vnto other Bodies*: for that which is encompassed on euery side cannot be called a Part but a Whole. Now whereas the Part must helpe to compound the whole, it is necessarie it should adhere or cleave vnto it by a connexion of quantitie; wherefore in the whole Body, a Part hath a true existence, and is in deed ioyned thereto, but in reason diuided therefrom. But both these definitions seeme to me to be too large, comprehending not onely the liuing Particles of the Body (which are onely true parts, because they alone performe actions, and are affected with diseases) but also those that are without Life, as Haires, Nailes, Fat and the Marrow of the Bones. *Fernelius* hath left vs a most perfect and absolute definition of a Part in these words, *Pars est corpus toti coherens, communis, vita coniunctum, ad illius functiones usumq, comparatum*. A Part is a Body cohering or cleaving to the whole, and ioyned to it in common life, framed for his use and function. From hence we may gather, that two things are required to accomplish the nature of a Part: First, that it should cleave vnto the whole, and next, that it should haue some end or vse. The coherence of the Part to the Whole is by a double connexion, one Mathematicall, another Physicall: The first is a coherence of quantities; for a part of the Creature being separated from the whole Creature, cannot be called a part of that whole, vnlesse it be equiuocally. The later connexion is called specificall, and is a vnion of life: For a dead or mortified Part, although it haue a coherence with the whole, yet may not be called a Part but equiuocally, because it hath not an vniuocall forme with the whole. But because *Fernelius* in the second Booke of his *Physiologie*, hath canuased this definition & all the minutes thereof very exactly, I will not at this time insist vpon the explication of it, it may be we shall haue fitter oportunitie for it hereafter.

CHAP. XVII.

What an Anatomist must consider in euery Part.

Three things
are to be con-
sidered in a
Part.Structure
what it is.The substance
of a part
what it is.The temper
what it is.

Anatomists do obserue many things in euery part, which *Galen* in his Bookes *De Vsu Partium* referreth to nine Heads. We, the better to auoid confusion, lest the wits of those that are ignorant should be too much racked, will consider onely three things, to which all the rest may be referred, the *Structure*, the *Action* and the *Vse*. The word *Structure*, I take here in a large signification, as *Aristotle* and *Galen* haue often taken it; not onely for the conformation, but for whatsoeuer addeth or helpeth any thing to the constitution or composition of the Part. Now these three things goe to that constitution, the Substance, the Temper, and the Conformation. The Substance (as we said before) is the Mansion of the particular and determinate facultie, and is peculiar to euery part; and in that respect, the Substance of a Part is said to be bony, membranous, neruous, fleshy, medullous or marrowy. This Substance it hath partly from the Forme, partly from the Matter, and it is known by sensible qualities, such as are hardnesse, softnesse, thicknesse, thinnesse, raritie, densitie or thightnesse, colour and fauour or tast. The Temper accompanieth this Substance & hangeth vpon it, following the materiall qualities; for it is not a thing abstracted or separated, but hath a firme coherence with the Matter or Substance, as with her Subiect; and therefore the Physitians call the Temper, the Forme of the similar Parts, although indeed it be not so much; but onely *πρῶτον δεκτικόν*, that is, the immediate receiuer of the Soule. This Temper the Physitian especially standeth vpon; for euery Part worketh thus or thus, according to

and

and by his temper; and he that will maintaine the actions or functions of the Parts, must haue especiall care to preferue their true and genuine temper. In respect of this temper, the Parts are said to be hot, cold, moyst and dry; alwayes hauing a respect to a *medium*, that is, to a thing of a meane and middle temper, that is the Skin. A hot and a cold temper we distinguish rather by reason and discourse, then by sense, because in a liuing Creature there is nothing actually cold. But the moyst and dry temper sense onely discouereth, that is, the hardnesse or softnesse of the part; for whatsoeuer appeareth hard to him that toucheth it, that we resolute is dry, because in a liuing Creature there is nothing hard by concretion or curdling; whatsoeuer feeleth soft, is moyst. The conformation of a Part consisteth in the Symmetry, that is, the naturall proportion or constitution of many things, to wit, of the Figure, Magnitude, Number and Scituation. To the Figure we referre the Superficies or Surface, the Pores & the Cavities. To the Scituation we referre the Seat and position of the Part, as also his connexion with others; for the Parts doe not hang loose in the Body, or separated one from another, but they haue a coherence, being tyed together by Ligaments and Membranes. And therefore it behoueth a Physitian and Chirurgeon to know which parts are tied to which, that when one part is affected, he may know what parts may be drawne into sympathy and consent with it. To this conformation *Galen* referreth the beautie of the Part, which he conceiveth to reside in *ὁμοιότης*, that is, in the equality of the Particles; but we place the beautie of the whole Body, in the inequality of the Parts, that is, in their vnlike and different qualitie & magnitude; but yet such a difference as whereby the Parts doe answer one another in an apt and neat correspondencie of proportion, even as Musicke is made of different sounds, but yet all agreeing in a harmonious consent; and thus much of the Structure of a Part.

Next followeth the Action, which *Aristotle* calleth *The end of the Structure*; because for the Action sake, the Part hath his Substance, Temper & Conformation. So the Heart, because it was to be the Mansion and habitation of the Virall facultie, and the Store-house of Arteriall blood, hath giuen vnto it a fleshy and solid Substance, a Temper hot & moyst, a Figure somewhat long, but comming neere to the Sphericall, hollowed also with two Ventracles or Bosomes, and many obscure Cavities, in which the Household-Gods and Fire-harth of the Body were to remaine, from whence there should issue & spring a continuall supply of natieue heat and spirits. I define an Action with *Galen*, *A motion of the working Parts*, or *A motion of the Actor*, to distinguish it from an Affection; for an Affection is a passive motion, or a motion of a passive or suffering Body; but an Action is *Motus effectiuus*, an effectuating or working motion; so Pulsation is an Action of the Heart; Palpitation is an Affection or a passion; the first proceedeth from a Facultie, the second from a sickly or vnhealthfull cause, which we commonly call *Causa Morbifica*.

Of Actions some are common, some are proper; the common Actions are found euery where; the proper are performed by one particular Part. Nutrition is a common Action, for all liuing and animated Parts are nourished, because life is defined and limited by Nutrition. Proper Actions are performed by a particular Organ, and they are either principall, or such as minister to the principall. Againe, of Actions some are Similar, some Organicall. A Similar action is begun onely by the Temper, and by the same is perfected, and is performed by euery sound and perfect Particell of euery Part. The Organicall is not commenced by the Temper onely, neither is it accomplished by the Particles, but by the whole Organ or Instrument.

Finally and in the last place, the vse of the Part must be considered by the Anatomist; For the Philosopher saith, that we are led vnto the knowledge of the Organ, not by his Structure but by his Vse. The Vse which the *Gracians* call *χρῆσις*, is two-fold according to *Galen*. One followeth the Action, that is, ariseth from the Action it selfe, and is the end of it; as by the Action of Seeing, the Creature hath this Vse, that he can auoid that which is hurtfull, and pursue that which is behoofefull. This Vse, if you respect the Generation and constitution of the Part, is after the Action; but in dignitie and worth it is before it, because it is the end of all Actions: Now the End is more excellent then those things that appertaine or lead vnto that End. The other Vse goeth before the Action, and is defined to be *A certaine aptitude or fitnessse to doe or worke*. So in the Eye the Christalline humor doth primarily make the Sight; the other humors, the Coates, the Optick-nerues afford a Vse, and are ordained to perfect the Action of Seeing. This Vse is in dignitie behind the Action, but in generation before it: By which it is manifest that the Action differeth,

and is another thing from the Use, although many Men use to confound them. For the Action is an active motion of the Part, but the Use an aptitude for Action. The Action is onely in operation, the Use remaineth also in the rest or peace of the Member: the Action in euery Organ is onely the worke of the principall Similar part in that Organ, the Use is likewise of all the rest. To conclude, there are many parts which haue Use without any Action, as the Haires and the Naailes.

CHAP. XVIII.

The differences of Parts: And first, HIPPOCRATES his diuision of Parts.

HE diuision of the diuine Senior, in his sixth Booke *Epidemion*, is of all other the most ancient, into *ἰσχυρά, ἰσχυρὰ καὶ ὀρμῶντα*, that is, *Containers, contained and those that are impetuous*: To use the Martialists word, doe make impression. Alexander more plainly diuideth the Body into *σῆμα, ὕγρὰ καὶ πνευματώδη*, that is, *Solid, Humid and Spirituous parts*. We diuide them into Parts nourishing, to be nourished and impulsue Parts. The containing Parts are solid, and such as are to be nourished. The name of solid I doe not take as the common People doe, for that which is hard and tight, or dense; nor for that which is contrarie to rare and hollow, but with the best Philosophers, by solid I vnderstand that which is *ἰσχυρὰ τὰ τε*, that is, which is wholly full of it selfe not of any other thing, or which hath a nature euery way like vnto it selfe. For *Solum* and *Solidum* in Latine, doe come of the Greeke word *δαῖον*, by changing the Aspiration into a hissing, and so is set before *δαῖον*: And thus the fleshy Parts also may be called solid and containing Parts. So the Heart a fleshy Entraile, containeth in his right ventricle Venall, in his left arteriall Blood. So the marowy substance of the Braine, which hath in it many dens and caviities, containeth both humors and spirits. We call also all solid Parts, Parts to be nourished, because whatsoever is solid, the same is similar, and the action of a similar Part is Nutrition.

Contained Parts are the humors concluded or shut vp in their proper Vessels and Conceptacles, as it were in Store-houses. Galen calleth *τὰ ὄργανα*, that is, humors, *τὰ ἐν τοῖς ἀγέστοις ἐμπεριόμενα καὶ κατὰ πᾶν σῶμα διασπαρμένα*, that is, such as are contained in the Vessels, and dispersed through the whole Body. Some had rather call them *ἰσχυρὰ*, *Things detained*, the better to signifie those things which are contained within vs, as also which doe preserve the substance of the Part: And therefore we haue called them Nourishers, to restrain the word *Humors* to the Alimentarie, and not to include the Excrementitious.

ὀρμῶντα or *ἰσχυρὰ*, that is, impulsue or impetuous things, *Fernelius* referreth to the faculties of the Soule; not to the Spirits; but in my opinion he is in this out of the way. For though the Spirits be contained, and haue proper conceptacles, to wit, the Veines, Arteries & Nerues, yet they are truly called impulsue substances; and *Hippocrates* spake of the Body & bodily things, and therefore not of the Faculties, which are but abstracted Notions. Now by the word Spirit, I do not vnderstand a wind, for these are *ἀνδροειδέα*, *Bastard*, or as *Anicen* termeth them *Fraudulent spirits*, whose violence is sometimes so great and furious, that they are the cause of many tumults in the household government or naturall constitution of the Body, which is often-times miserably distressed with their furious gusts: Read what *Hippocrates* in his Booke *De Flatibus* hath written of the power of Winds. But by Spirits we vnderstand the primarie and immediate Instrument of the Soule, which the Stoicks calleth the *Band which tyeth the Soule and the Body*. The force of these Spirits is such, and so great the subtiltie and thinnesse of their Nature, that they can passe suddenly through all parts, and doe insinuate themselves through the fastest and thickest substances, as we may perceiue in the passions of the mind, in sleepe and in long watchings. By the ministerie of these Spirits, all the motions of liuing Creatures are accomplished, both Naturall, Vitall and Animall, and by these, life, nourishment, motion and sense, doe flow into all the parts. Finally, the motion of the Spirits is perpetuall, both of themselves, and by another. By themselves, that is, they are moued continually from an inbred principle both wayes, vpward and downward; vpward because they are light, downward toward their nourishment. They are moued by another when they are driuen and when they are drawne. The Vitall Spirits are driuen, when the Heart is contracted, the

Animall when the Braine is compressed. The Spirits therefore are *εὐκίνητοι* impetuous substances. They are fiery and ayery, and therefore very fine, subtle and swift: So the Seed although it be thick & viscid, yet in a moment it passeth through the vessels of Generation, which haue no conspicuous cauities, and that because it is spirituous, or full of Spirits.

There are also other differences of Parts, according to *Hippocrates* in his Booke *De Veneri Medicina*, which are drawne from their Substance, Figure and Scituation. From the Substance, some are dense, others rare and succulent, or iuicie; others spongie and soft. From the Figure, some are hollow, and from a largenesse gathered into a narrownesse or constraint, others are stretched wide; others solid and round, others broad and hanging, others extended, others long. From the Scituation, some are anterior, some posterior, some deepe, others middle, vppermost, lowermost, on the right hand and on the left.

CHAP. XIX.

A diuision of Parts into Principall and not Principall.

THE diuision of Parts into principall and lesse principall, is verie famous, and hath held the Stage now a long time. We define, that to be a principall Part, which is absolutely necessarie for the preseruacion of the *Individuum* or particular Creature: Or, which affordeth to the whole Body, a facultie, or at least a common matter. In both Senses, there are onely three principall Parts, the Braine, the Heart and the Liuer; the Braine sitteth aloft in the highest place, as in the Tribunal or Iudgment-seat, distributing to euerie one of the Instruments of the Senses, their offices of dignitie. The Heart (like a King) is placed in the midst of the Chest, and with his vitall heat, doth cherish, maintaine and conserue the life and safetie of all the Parts. The Liuer, the Fountaine of beneficall humor, like a bountifull and liberall Prince at his proper charges, nourisheth the whole Family of the Body. From the Braine, the Animall facultie by the Nerues as it were, along certaine Chords, glideth into the whole frame of Nature. From the Heart, the Vitall spirits are conueyed through the Arteries, as through Pipes and Water-courses into euerie Part. From the Liuer, if not a Facultie, yet a Spirit; if not a Spirit, yet at least a common matter, to wit, the Blood is diffused by the Veines into euerie corner. So that onely three are absolutely necessarie for the conseruation of the whole *Individuum*, the Braine, the Heart and the Liuer, all which are fitted and tyed together in so strait a conspiracie, that each needeth the helpe of the other; and if one of them faile, the rest perish together with it. Not that I thinke these parts are of equall dignitie, for the Heart is more noble then the Liuer, and the Braine more excellent then the Heart, as well because his actions are more diuine, being the Seat and Palace of Reason, which is the Soule; as also, because all other parts are but Hand-maids vnto it: And besides, *Hippocrates* saith, it giueth the forme to the whole Body, *For (saith he) the Figure of the rest of the Bones, dependeth vpon the magnitude of the Braine, and the Skull.*

Galen addeth to the principall Parts, the Testicles, because they are the chiefe Organs of Procreation, by which alone, the species or kind is preserued. But we thinke that they conferre nothing to the conseruation of the *Individuum* or particular Creature, because they neuer afford any matter to the whole Body, neither Facultie or Spirit, but onely a Qualitie, with a subtle and thin breath, from whence the Flesh hath a seedy rammishnes, a harsh tast and strong sauour, and the actions strength and validitie. All the rest of the parts may be called ignoble compared to these, as well because from them proceedeth no Facultie, Spirit or common matter, as also because euerie one of them, doe minister to some one or other of the principall Parts. So the Organs of the Senses serue the Braine, and were created for his vse and behoofe: So the Lungs, the Midriffe and the Arteries, as well smooth as rough, were ordained onely for the tempering and repurgation of the Heart: So the Stomach, the Guts, the Spleene, both the Bladders of Vrine and of Gall, were made for the Liuer: And in a word, none of these ignoble parts are of necessitie for the conseruation of the Creature, or if they be necessarie, it is not *ἀπλῶς*, that is, simply and absolutely, but *secundum quid*, that is, as they are necessarie to serue the turne of the principall. For I pray you, what vse hath the Arme, the Legge or the Stomach of the Lungs, the Spleene and the Kidneys? Againe, what necessarie vse haue the Lungs, the Spleene and

and the Kidneys of the Legges or Armes? But to all these the Heart giueth Life; the Liuer Nourishment, and the Braine Sense and Motion, so that the Braine, the Heart, and the Liuer are in all the parts of the Body, by the mediation of their Vessels. Now, as there is not an equalitie of dignitie among the principall Parts, so the ignoble Parts are not all of one and the same degree. For some of them serue the principall by preparing some-what for them, others by carrying or leading some-what vnto them. There are also some ordained onely for the expurgation or cleansing of the principall, which are the most ignoble of all the rest, and are commonly called Emunctories or Drayners. So for the Liuer the Stomach boyleth the Meat, the Veines of the Mesenterie giue the Blood a kind of rudiment or initiation; the Caue or hollow Veine disperseth the Blood already perfected. For the Heart the Lungs prepare the Ayre, the Pipes of the great Arterie carrie about the Vitall spirits. For the Braine the wonderfull texture or plighted web of Vessels prepares the Animall spirit, and the Nerues distribute it into the whole Body. Behind the Eares are the Emunctories or Drayners of the Braine; vnder the Arme-holes so many Glandules or Kernels which receiue the superfluites of the Heart, and in the Leske or Groyne are the Emunctories of the Liuer.

CHAP. XX.

A diuision of Parts into Similar and Dissimilar, and an interpretation of the same.

All the names
of the similar
Parts.
Plato.
Aristotle.

THE most frequent diuision of the Parts among Philosophers and Physitians, is into Similar and Dissimilar, which is also the most necessarie for the exquisite disquisition and distinction of Diseases. The Similar parts, Plato first called *πρωτόγωνα*, that is, *First borne*, because according to the order of Generation, they are after a sort before the compound Parts; and because they are the first *Stamina*, Threds or Warp of the Body. Aristotle calleth them *ἀπλά καὶ ἀσύνθετα μέρη*, that is, *Simple and uncompounded Parts*, because they are not compounded of other parts, or else *πρὸς τι*, that is, *in respect of the compounded*: For they are not in deed and truly simple, for the Body of the Creature being not simple; neither can the parts of it be truly simple.

Anaxagoras.
Aristotle.

First *Anaxagoras*, and after him *Aristotle* brought in the name *τῆς ομοιογενείας*, of *similitude*, whence they are called Similar, because they haue one & a like substance. Some call them *πρὸς ἑαυτὴν μέρη*, that is, *Continuall Parts*, because they are continually the same both in matter and forme. Others call them *Informes*, without *Forme*, but we thinke it better to call them *Vniforme parts*. Aristotle called them *Sensorias*, because that which is Similar is capable of sensible objects, and all sense originally proceedeth from the Similar parts. *Galen* calleth them some-times *Sensible Elements*, because they appeare to the Senses most simple and vncompounded; some times *ἐλάχισα κομμάτια*, that is, *The least Particles*. Some-times the *First*, sometimes the *Last bodyes*; *First*, in respect of their composition; *Last*, because into these the Body is dissolued as into the least parts that may be distinguished by the perceiuing Senses. Some call them *Solid*, not because they are constant, euer consisting and neuer diffuent (for then the Flesh should be no Similar part) but because they are euerie way full and compleate. The common people call that Solid, which is hard, dense or compacted; for Water or a Sponge, they will neuer acknowledge to be Solid: But the Philosopher calleth that Solid, which is wholly full of it selfe, and of no other thing, which is of a like or of the same nature; so the Fire in his owne Globe, and the Heauen (although they be most rare and subtile Bodyes) yet true Philosophers will call them Solid bodyes. *Hippocrates* calleth them *ἰσχυρὰ*, that is, *Containing Parts*: But enough of the name, now let vs come to the Essence of the Similar parts.

Aristotle.
Galen.

What is a
solid part.

Hippocrates

A similar part
hath a double
consideration.
A definition
of a similar
part.
Aristotle.
Galen.

A Similar part may haue a double consideration, one in respect of the Matter, another in respect of the Forme: If you regard the Matter, which is altogether one and the same, in all parts like vnto it selfe; then shall Similar parts be defined according to *Aristotle*, *ὅσα διαφέρουσιν αἰς ὁμοιογενείαν*, which are divided into parts like vnto themselves. According to *Galen*, *All whose Particles are like to themselves and to the whole*: Or, *Which are divided into parts not differing specie, or in kind*. If you respect the Forme of the Similar parts, then they shall be defined, *Such as haue an vniforme Figure*. For, because the Forme giueth the proper denomination to euerie thing, that shall be called *Similar*, which hath a similitude

or

or likenesse of Forme and Figure. In the first consideration or respect, euerie Particell of the Similar part retaineth the name of the whole, but not in the latter: So the Bone of the Legge because of the similitude of the Matter is vniforme, but if you respect his Figure, then are not all his parts of the same nature, for euerie little Particell of that Bone is not hollow, though the whole Bone be hollow. Hence we may gather that euerie Similar part may be said to be Organicall, and that they doe not well who oppose Similar and Organicall parts for *diuiding members*, as we say in Schooles: For among Philosophers, the nature of the part & of the whole is the same. The whole Body is Organicall, because *The Soule is an act of an Organicall body.*

Euerie similar part may be said to be organicall. *Membra diuidentia*

The Essence of the Similar parts seemeth to consist of an vncertaine medley of the Elements, and a temper of the foure first qualities, Heat, Cold, Moisture and Drought. And therefore the Physitians say, the Temper is the Forme of the Similar parts, because it is *πρῶτον δεκτικόν*, *The first receiver*, and the first power with which & by which, the Forme worketh; and the Similar part, as it is Similar, suffereth whatsoeuer the Forme worketh. So Nutrition, which is the common action of the Similar parts, is inchoated or begun by the Temper alone, by it is perfected, and plenarily and perfectly accomplished by euerie Particell of the Part.

The Essence.

The differences of the Similar parts, are some of them belonging to the Philosopher, some to the Physitian. The Philosopher rayseth his differences from the first qualities, and those which follow the Temper. The Physitian from the sensible and materiall principles of Generation. The first qualities are indeed foure, but because Heat and Cold are certaine acts, and an act is according to it selfe indiuisible, therefore the Philosopher rayseth his differences onely from the diuersitie of Drought and Moisture. Wherefore *Aristotle* maketh Similar parts, some dry, some moist. The moist are either properly so called, that is, such as of their owne nature cannot containe themselves within their owne *termini* or limits, and therefore do stand in need of conceptacles or receptacles, as the Blood; or else are soft, which doe better containe themselves within their bounds, as Flesh. The dry are those whose Superficies or Surface if pressed, yeeldeth either not at all, or verie hardly: And such he calleth *σπῆλαια*, or *σπῆλαια μέρη*, that is, *Solid parts*; of which he maketh two kinds. Some are fragile or brittle, which cannot be bent without the dissolution of the part, as Bones; others, are tough or stretching, which may be bent and extended without dissolution, as Ligaments and Membranes.

The differences of similar parts.

A Philosophicall diuision of them into moist and dry. *Aristotle.*

The Physitians doe gather the differences of Similar parts, from the sensible and materiall Principles of Generation. There are two materiall Principles, the Crassament or substance of the Seed (for onely the Spirits or the Workmen) and Blood: and therefore some parts are spermatieall, and some fleshy. The first are immediately generated out of the Crassament of the Seed, the latter of Blood: The first in growne and old Men, doe hardly reunite *κατὰ πρῶτον σκοπόν*, *according to the first intention*, as we vse to speake, because of the weakenesse of the efficient (for they are cold;) because of the vnapt disposition of the Matter, whose affluence is no confluence, that is, it floweth not together-ward and *ἀθροῖται*, *at once*; and because it must passe through many and diuerse alterations; add hereto the siccitie and hardnesse of the parts; for dry things doe not easily admit a vnion or consolidation, and the Philosopher in all mixtion requireth a waterie moisture, that by it as by Glue, all parts may be vnited. On the contrarie, fleshy parts, because they are hotter, softer and nourished with Blood, little or nothing at all altered, do presently re-vnite and close together, sometimes without any meane immediately; sometimes *per medium homogeneum*, that is, by a thing of the same kind.

The Physitians diuision of them into spermatieall and fleshy

There are diuers differences of spermatieall and fleshy parts. For the Seed, though it seeme to be similar, vniforme & euerie-where like it selfe, yet hath it parts of a different nature, some thicker, some thinner, some fat, some slimy, some fit for stretching, others for concretion or to be gathered together. Whilst therefore the procreating vertue worketh vpon that part of the Seed which can extend it selfe, it maketh Membranes, Veines, Arteries and Nerves; when vpon that which is fitter for concretion, it formeth Bones & Gristles; when the fat is more then the glutinous matter, then are Bones & Gristles formed.

The differences of spermatieall parts.

Againe, *Galen* obserueth in the spermatieall parts, a double substance, that which is truly solid, and that which is fleshy; the first may be moistned, but not restored; the other is as it were a concrete or congeled liquor, cleauing to the solid Fibres. There are three kinds of fleshy parts, three sorts of flesh. One *Flesh* properly so called, to wit, that of the

Galen. In spermatieall parts there is a double substance. Three sorts of flesh.

the

Hippocrates

the Muscles, which therefore *Hippocrates* calleth absolutely *σάρκα*, that is, *Flesh*. There is another *Flesh* of the Bowels or inward parts, which we call *Enterals* and *παρίχυμα*, as it were an affusion or confluence of Blood. There is also another *Flesh* of the particular parts.

A third diuision of the similar parts.

We will adde a third diuision of Similar parts, into Common and Proper. I call those Common, which make and constitute many parts of an vnlike and different nature, as the Bones, Gristles, Ligaments, Membranes, *Flesh*, Nerues, Veines and Arteries. Of which, the first five are truly Similar, the others onely according to sense: For the inner substance of a Nerue is Medullous, the outward Membranous. I call those Proper, which doe make the substance onely of one part, and such as is not found else-where; such are the marrowy substance of the Braine, the cristalline and glassie humors of the eye. Of all Similar parts there is a double necessitie: One, that of them Dissimilar parts may be compounded; the other I find in *Auerrhoes*, that they may be the Seat of the Sensatiue vertues, for all sense commeth by the Similar parts.

The necessitie and vse of similar parts. *Auerrhoes*.

What is a dissimilar part.

To the Similar part, we oppose the Dissimilar; for as the Similar part is, or may be diuided into Particles of a like, so Dissimilar into Particles of an vnlike or different kind: As the Particles of the Similar part retaine the name of the whole, so the Particles of Dissimilar parts haue no names at all. Wherefore we define Dissimilar parts to be, *Such as are diuided into parts of a different nature and diuers kind*. These the Physitians κατ' ἐξοχήν, by way of excellence doe call Organically, because their action is more perfect and euident, as also because the neatnesse of the Figure, the Magnitude, Number & Scituation (which foure accomplish the nature of an Organ) do more plainly appeare in compounded parts then in simple; so that both in respect of the Forme and of the Actions, they are more properly called the Organs of the Soule; for the Forme of the Similar parts is the Temper, of the Dissimilar a laudable conformation: Now conformation doth better answer the functions of the Soule, then doth the Temper, because the Soule is defined to be *An act of an Organically body*. The Action of the Similar is naturall, to wit, Nutrition, as being manifest euen in Plants; the Action of the Dissimilar part is animall, and therefore that is said to be the Action of Nature, this of the Soule. Furthermore, I define an Organ (with the Ancients) to be a part of the Creature which can performe a perfect Action; by perfect I vnderstand proper: For the Action of the Similar parts is common, not proper. *Galen* maketh foure orders of Organs or Instruments: The first is such as are most simple, which consist onely of Similar, as the Muscles. The second are those that are composed of the first, as Fingers. The third are such as are made of the second, as the Hand. The fourth are such as are made of the third, as the Arme. Againe, In euerie perfect Organ we may obserue foure kinds of parts; The first is of those by which the Action is originally performed; where these are, there is also the Facultie; and therefore they are said to be the principall parts of the Organ; such is the cristalline humor in the Eye, for it onely is altered by colours, and receiue the Images of visible things. The second kind is of those without which the Action is not performed, and these doe not respect the Action primarily and of themselves, but the necessitie of the Action; such are in the Eye, the Opticke nerue, the Glassie humor and the albuginious, which is like the white of an Egge. The third kind is of those by which the Action is better performed; and these respect the perfection of the Action, and therefore are called *Helpers*, such are in the Eye, the Coates and the Muscles, which moue & turne the Eyes with a wonderfull volubility. The last kind is of those parts which doe conserue or preserue the Action; these are the causes that all the rest doe worke safely; and they respect the Action, not as it is an Action simply, but as it is to continue and indure; such in the Eyes, are the Browes, Lids and Orb of the Eye; and this is the nature of Dissimilar and Organically parts. But that we might not passe ouer any thing, we will adde this one for a complement; That of Dissimilar parts, some are such by the first Institution of Nature, as the Hands and the Feet, from which if you take all the Similar parts, you shall reduce them into nothing; others are Dissimilar secondarily, because of the implications and textures of Veines, Arteries and Sinewes in them, as the Heart, the Braine and the Liuer; for if you take from the Braine the common Similar parts, yet there will remaine the proper substance of the Braine.

The dissimilar parts are rather the Instruments of the Soule then the similar.

What an Organ is.

Foure orders of Organs.

In a perfect Organ there are foure kinds of parts

Per se.

Another diuision of dissimilar parts.

CHAP. XXI.

The other differences of the Parts are unfolded.

Here are also other differences of Parts not so necessarie for a Chirurgion to know, which notwithstanding because we would leaue nothing behind vs, we will briefly declare. *Galen* in his Booke *De Arte Parua*, maketh foure differences of Parts: Some Parts are principall, as the Braine, the Heart, the Liuer and the Testicles. Some doe arise from these principall and minister vnto them, as Nerues, Veines, Arteries and Seed-vessels; some neither gouerne others, nor are gouerned of others, but haue onely inbred Faculties, as Bones, Gristles, Ligaments, Membranes. Finally, some parts haue vertues both *inbred* and *influent*, as the Organs of Sense and motion. The *Arabians* gather the diuisions of Parts, from the Substance, the Temper, those things which follow the Temper, and those things which are accidentarie or happen to the Part: Whence some parts are fleshy, some spermaticall; some hot, others cold; some moist, others dry; some soft, others hard; some moueable, others immoueable; finally, some sensible, others insensible. Those which haue sense, haue it either sharpe and quicke, or stupid and dull. A Part is said to haue exquisite sense three wayes, either because of the perfection of the sense, so the skin which couereth the palme of the Hand, and especially the Fingers ends, hath an exact perception of the tractable or touchable Qualities; or because it is more easily and sooner violated and offended by the internall and externall Qualities which strike the Sense; so the eye is said to be of verie acute and quicke sense, or because it hath a determinate or particular sense, which nowhere else is to be found; so the mouth of the Stomach is of most exquisite sense, that it might apprehend and feeie the exhaustion or emptinesse, and the suction or appetite of the other Parts: So also the Parts of Generation in both Sexes, haue in them a strange and strong desire and longing after their proper satisfaction.

The Anatomists commonly doe diuide the whole Body into the Head, the Chest, the lower Belly & the ioynts. The *Egyptians* into the Head, the Necke, the Chest, the Hands and the Feet. *Diocles* into the Head, the Chest, the Belly and the Bladder. *Fernelius* in the second Booke of his Method, diuideth the Body into publike and priuate Regions: And truly as I thinke verie commodiously for a practising Physitian or Chirurgion. The publike Region is three-fold: One, and properly the first, reacheth from the Gullet into the middle part of the Liuer; in which, are the stomach, the Meseraicke veines, the hollow part of the Liuer, the Spleene, and the *Pancreas* or Sweet-bread betweene them. The second runneth from the midst of the Liuer, into the small and hairie Veines of the particular parts, comprehending the Gibbous or bounding part of the Liuer, all the hollow Veine, the great Arterie that accompanieth it, & whatsoeuer portion of them is between the Arme-holes and the Groyn. The third Region comprehendeth the Muscles, Membranes, Bones, and in a word, all the *Moles* or Mountenance of the Body. There are also many priuate Regions, which haue their proper superfluities, and peculiar passages for their expurgation.

And thus me thinkes I haue run through the nature of Man, the Excellencie, Profite, Necessitie and Method of Anatomie, who haue written thereof as well in old times, as of later yeere, and among our selues; the definitions and diuisions of Anatomie,

the Subiect or proper Obiect of the same, the nature of a Part, with the differences and distributions of the same: It remaineth now,

that we vntie such knots as might in this entrance intrangle vs, and so hinder our progresse to that wished end which we set before

vs.

Galen maketh foure differences of Parts.

How the *Arabians* distinguish the Parts.

The *Egyptians* diuision of the Body. *Diocles*. *Fernelius* his excellent diuision of the Body.

A
Dilucidation or Exposition of the
Controuersies concerning the Subiect
of ANATOMIE.

The Preface.

IN the knowledge of Diuine Myserie, Implicit Faith is the High-way to Perdition, so in Humane Learning, nothing giues a greater checke to the progresse of an Art, then to beleue it is already perfected and consummated by those which went before vs; and therefore to rest our selues in their determinations. For if the ancient Philosophers and Artists had contented themselues to walke onely in the Tracke of their Predecessors, and had limited their noble wits within other Mens bounds, the Father had neuer brought forth the Daughter, neuer had Time brought Truth to light, which vpon the fall of Adam was chayned in the deepe Abyss. There is, as of the World and gouernment thereof, so of Arts a frame, the matter whereof comes downe from Heauen, but is gathered here by discourse of reason and experience. The beautie and glorie of whose Columns were not perfected in one Age, but the Ground worke was first layd in the times which were neerest to the originall of Nature; afterward addition was continually made by the vigor of the Soule of Man, and shall be vnto the end of the World. It were not hard to giue instances hereof in all Arts, nor haply would it be verie tedious; but it shall be sufficient (to auoyd prolixitie) to insist a little vpon generalls, and so descend vnto our owne Art we haue in hand. The first Man (saith the Diuine Storie) saw all the Creatures, and gaue them names according to their Natures, but that Sunne-shine was soonē clouded, that Image defaced, that Stampe battered by his fall. Afterwards, as a Merchant that had lost all his Inheritance in one Bortome, he was to begin the World anew, and to gather an estate or stocke of knowledge, by the trauell and industry of his Soule and Body; yet was not his Soule *Abrasa Tabula*, A playned Table, there remained some Lineaments which the Scripture calleth, *The Law of Nature*; not such as could exhibit any sufficient originall knowledge, but such as whereby, hauing gotten knowledge from without himselfe, might make him againe acknowledge the darke and defaced Foot-steps that remained in himselfe, and to polish and refresh them somewhat, though it was impossible to reduce them to the former perfection. Thus the Soule by discourse of Reason, that is, by her owne act, knew her naturall immortalitie, and by induction of particulars, came to informe her selfe of the Natures of other things: Not as she knew before, from the vniuersall to particulars, but by gathering particulars together to frame generall and vniuersall notions.

And surely in the first Age, by reason of their long life, and consequently of their infinite obseruations, haply also because they were neerer to integritie of Nature, the Defection

tion not being so suddenly confirmed, Men layd the grounds of Arts, which were deli-
 uered by Tradition from the first Fathers simply and faithfully; but afterward by enue
 or corruption were wrapped vp in mystical Hieroglyphicks, or poysoned with Supersti-
 tion, or forfeited by Negligence, many of them also were worne out by length of Time,
 for want of Letters and meanes to performe them. Those which remained, ran in Fami-
 lies, and from Families were deuolued vnto Nations as the World encreased: First, as is
 supposed, to the *Chaldeans*, then to the *Phenicians*, after to the *Egyptians*; all which, as the
 Nature of Man is prone to worke vpon that, it can least attaine vnto; or else, because the
 Diuinitie of the Soule finding no contentment in that she conceiued to be lesse then her
 selfe, did therefore neglect all sublunarie things, and applyed it selfe to speculations of
 Heauen and heauenly Bodyes, wherein Men were furthered by that old and cunning Ser-
 pent, who put to his helping hand to seduce them from the acknowledgment of their own
 imperfection, by goading them forward in an addle and vaine disposition of friuolous
 and impious secrets. So the Tradition of God, as being of too high a pitch for their im-
 ped wings, was peruered vnto an vnknowne *Numen*. The Tradition of Angels into feig-
 ned Spirits, gouerning the motions of the Heauens. That of the true vse of the Starres
 into Iudiciall and Genethliacall Astrologie. That of the fall of *Adam* and *Eue* into the
 Fable of *Isis* and *Osiris*. The Deluge into *Deucalions* Flood. The Diuinitie of the Mind
 and Soule into the Tale of *Mitris* and *Ariminis*, and a world of such superstitions Toyes.
 And verily almost all such was the learning of the former Ages, till the *Gracians* fell vpon
 the grounds of Demonstrations: And then Men first began to fall from those abstruse
 and transcendent contemplations, and to bring home Philosophy vnto themselues. Their
 Metaphysickes were Logically, their Physickes Elementarie; the Diuinitie of the Soule
 was tyed to the Principles of Generation, and supposed to result out of the power of the
 matter of the Body: And in a word, Philosophy fell from Heauen into the Elements,
 wherein they so accombred themselues, and those that followed them, that to this day we
 are scarce vninthrallled from them. Yet there wanted not some, who labored in all kinds,
 to bring Learning to better thrift: *Homer*, *Hippocrates*, *Plato*, all of them in their kinds, the
 verie Oracles of Philosophy, so as we may truly say, that whatsoeuer we haue solide and
 substantiall, it is but deriued from their Fountaines.

Neither were these Men onely happy in their owne sublime and diuine wits and ap-
 prehensions, but also in their Interpreters, *Virgil* to *Homer*, *Aristotle* to *Plato*, and *Galen* to
Hippocrates. The former two we let passe, as belonging to another *Forum*, *Hippocrates* as the
 first head of our Tribe, the Father and Founder of the Family of Physitians, left a goodly
 Inheritance to his Posteritie, which *Galen* (to passe by the rest) hath not mispent but much
 improued, and we who are *Artis Filij* may worthily be accounted Decoctors & Prodigals
 if we keepe not our Patrimonie together; nay, in this kind of Thrift, not to goe forward
 is to goe backward. Yet I must confesse, that after *Galen*'s time, and his Epitomizer *Oriba-
 sius*, who liued but in the next Age, Anatomy (for that is the end we driue at) lay raked vp
Patrio in puluere, till within some of our Memories. *Vesalius* albeit some-what importu-
 nately, yet verie learnedly, blew vp the all-most dead sparkes into a most luculent flame,
 at whose Beacon, all since his time haue teened their Torches, though haply being put to-
 gether, they may seeme to dim his Light by their multitude.

There is, and will alwayes be left *Locus Philosophandi*, scope enough, euen in this Little
 world for such as list to exercise themselues; and many haue with no small commendati-
 ons made prooffe of their agilitie, yet we must needs acknowledge, that the Ground-work
 of the Building, and not onely so, but the whole Frame was by the Ancients, reared vp;
 and therefore now if any Ornaments be added, they must be fitted thereunto. Wherefore
 we haue labored to bring all the subtleties and nouell inuentions of the later Writers, to
 the Touch-stone of the ancients Monuments; that as no Man should be defrauded of his
 due commendation; so the Crowne may remaine, where with so much dust and sweat it
 was gloriously merited; whereby we doe not desire to be accounted amongst the number
 of the Antagonists, but as a Herald of Honour, doe endeauor to Marshall the Field, and
 sometimes where the case is cleere, to ioyne in vmpeirment with the Spectators; or
 where it is difficult to assist them.

QUEST. I.

Of the definition of a Part.

Hippocrates
the Oracle of
Physicke.
Galen his
interpreter.

water.

Aponensis
definition of
a Part.

Galen's two
definitions.

Both too
large.

Fernelius
the French
Galen.
Argenterius
his caill at
Fernelius

Hippocrates, whose happy workes are the verie Oracles of our Art, and Galen his Interpreter, doe promiscuously vse the names of a Part, a Member and a Place, for the same thing. The Eye (saith Galen in the first Booke of his Method) we call a Member; neither is there any oddes which you call it, a Member, or a Part: If any Man shall say the Eye is a Part and not a Member, or a Member and not a Part; I will not in either contend with him. In his first Booke De Locis Affectis; Not onely the later Physitians (saith he) but many also of the ancients doe vse to call the Particles of the Body, Places. Hippocrates in his Booke De Locis in Homine, and De Victus ratione in morbis acutis, calleth also Parts, Places: Yet there are some who distinguish a Member from a Part, and a Particle from a Place. Aristotle calleth those onely Members which are compounded of Parts of diuers Natures, as the Head, the Feet and the Hands; and those that are Similar he calleth properly Parts. Theodorus in Aristotle, thinketh that the name of a Part or Place, is of larger extent then the name of a Member. So also Galen in the sixth of his Method, saith that the Eye may be called a Part or a Member; and the hornie Tunicle a Part, but not a Member. But because in these Philosophicall disquisitions, it becometh vs better, to stand vpon substances, then vpon words; we take no care whether you vse the name of a Part, a Member, a Particle or a Place; it concernes vs more to find out an essentiall definition of a Part.

Auicenna defineth a Part to be a Body ingendred of the first permixtion of the Humors, as the Humors doe consist of the first mixtion of the Meat, and the Meat of the Elements. But this definition of the Arabian, is too presse, strait and narrow, because it agreeth onely to Homogeny parts, and not to Heterogeny: For euerie Man may easily perceiue that Heterogeny or Dissimilar parts are compounded immediately of Similar, not of the first mixture of the Humors. And this Galen teacheth in plaine and expresse words, in his first Booke De Elementis, where he saith, That compounded Parts are immediately made of the Simple or Similar, the Simple of Humors, Humors of Aliments, Aliments of the Elements. They which would salue the Arabians credite, say that his definition is materiall, not formall; for both Similar and Dissimilar doe communicate in the matter, though their forme or difference be diuers; but they forget that an essentiall definition must expresse the Forme especially, because it is the chiefe part of the Essence, as that which giueth being to the Thing. Aponensis defineth a Part to be a solid and thicke Body, begotten of humidities or moistures, and adorned with the powers of Nature; Which definition labourerth of the same disease with the former, comprehending onely simple not compounded Parts.

Galen hath two definitions of Parts. The first, in the first Booke of his Method and the fifth Chapter, and in the first Booke De Elementis, cap. 6. The second is in his first Booke De Versu Partium. The first is this; A Part is that which accomplisheth or integrateth the whole: Or, whatsoeuer addeth any thing to the frame of a humane Body. The second is this; A Part is a Body which neither hath a proper circumscription of his owne, nor yet is on euerie hand ioyned with others. Both these definitions seeme to be too large, comprehending not onely liuing Particles (which are onely, truly and properly Parts) but those also which haue no life, as the Haires, the Nails, the Fat. Hippocrates also vseth this large and ample signification of a Part, in Lib. 6. Epidemion, where ὁμογενεῖα καὶ ὁμοῦρα, that is, Humors and Spirits he calleth Parts. So Aristotle calleth Seed, Blood, Milke, Marrow, Phlegme and Fat or Grease, Parts. Fernelius the French Galen, giueth vs a perfect definition of a Part, in the first Chapter of the second Booke of his Physiologia, and disputeth and scanneth the particuler branches of his definition learnedly & at large. Argenterius (a common Calumniator saith Laurentius) taxeth Fernelius definition, assuming a diuers consideration of Mans body: First as it is a Substance, and so he saith the parts of it are the Matter and the Forme; next as it is a Body, and so the parts of it are all the Corporeall substances therein contained; finally, as a liuing and animated Creature, and in that respect (saith he) whatsoeuer liueth, may be called a part of the liuing Creature, not a part of the Body. Wherefore Fernelius did ill define a Part of Mans body to be A Body cohearing or cleauiing to the whole, and ioyned to it in common life, framed for his vse and function.

But

But these are but nice and friuolous cauils, and indeed extrauagant from a Physitians consideration: For a Physitian doth not consider the Body of a Man as it is a naturall Body, consisting of Matter & Forme, but as it participateth of health, or is obnoxious or liable to sicknesse. And therefore *Fernelius* doth well determine that those Bodies onely are to be called Parts, which may be the Subiects of sicknesse and health. Now those Parts onely are afflicted with diseases, which performe some actions in the Body, and actions belong to living Parts, not to those which haue no life. For sicknesse is an indisposition which at the first hand and immediately hurteth or hindreth the action. And therefore *Fernelius* his definition is exquisite and perfect, becomming a good Physitian.

Fernelius
defended.

QVEST. II.

Of the principalitie of the Parts against the Peripateticks, prouing that there is not one onely Principall, to wit, the Heart.

Concerning the principalitie of the Parts, there is a famous difference betweene the Physitians and the Philosophers. The great *Genius* and Interpreter of Nature *Aristotle*, in the seuenth and the tenth Chapters of his second Booke *De Partibus Animalium*; in the fourth Chapter of his third Booke *De Partibus Animalium*; in his second Booke *De Generatione Animalium*; in his Booke *De Vita & Morte*; in his Bookes *De Somno* and *De Causa Motus Animalium*, determineth that there is but one Soueraigne in Mans body, and one Principle, which in his bosome & imbracement containeth and comprehendeth all the Faculties. And this he resolueth is the Heart, the Fountaine (saith he) of the Veines, Arteries and the Sinews; the Source of Heat, Spirits and quickning Nectar; the first and onely Store-house of Blood, or Worke-house of Sanguification; and finally, the Seat and Mansion-house of the Vegetatiue, Sensatiue and reasonable Soule. In *Aristotles* foot-steps haue walked *Auerroës* in the second of his *Collectanies*, *Aphrodisseus* in his first Booke *De Anima*, and many other both *Greekes* and *Arabians*: But they bring for confirmation of their opinion no necessarie Arguments, but such onely as are probable, shadowed ouer with a veile of truth.

Aristotle
would haue
but one prin-
cipal part, and
that the heart

It is more honourable (say they) and monarchicall, that there should be one Principle then many; and that the verie name of a Principle doth necessarily import so much. For if the Soule of the Creature be but one in number, and that indiuisible, then must the Body likewise of it be, either one whole, or at least haue some one Principall part; for Effences must not be multiplied without necessitie. And as in the great Vniuerse which we behold, there is one Principle, which *Aristotle* in the eighth Booke of his *Physicks*, calleth *Primum Mouens* and *Primus Motor*, that is, *The first Mover*.

The argu-
ments of the
Peripateticks:
The first.

Ὁὐκ ἔστιν ἄλλοτερον ἀντικειμενόν, ἐκ τοῦ κοινού.

'Tis naught to haue more Kings then one,
Let him that raignes, raigne King alone.

So in the *Microcosme* or Little world, there must be but one Principle, one Prince, which is the Heart, whose excellencie and dignitie aboue the rest of the Parts, these things doe cleerly demonstrate. First, because it liueth first and dyeth last; and therefore is the originall of Life, and the Seat of the Soule. Next, because it endureth no notable disease, but yeeldeth presently to Nature if it be afflicted. Againe, because it obtaineth the most honorable place, that is, the middle of the Body. Fourthly, for that by his perpetuall motion all things are exhilarated and do flourish: And nothing in the whole Creature is fruitful, vnlesse the powerfull vigour of the Heart do giue foecunditie vnto it. There (say they) is the Mansion and Tribunall of the Soule where heat is to be found, the first Instrument of all the Functions; but the Heart is the springing Fountaine of Natiue heat, which by the Arteries as it were by small Riuerets, is deriued into the whole Body. Moreover, the Seat of the Faculties is there, where the Organs of the same Faculties do appeare; but all the Veines, Arteries and Sinews, doe arise out of the Heart. For the Arteries no Man euer made doubt. The Veines doe surely arise thence, where their end and termination doth appeare: But that is about the Heart; for the implantation of the great Arterie and the

hollow Veine are alike. Beside, all the veines are continuat with the Heart, to it are they fixed, where they also haue Membranes set like Doores vnto them, which seeme to be the beginnings and heads of the Veines; but through the Liuer they are onely disseminated, and the rest of the Entrals they make a passage through, and so end into haire strings. Aristotle also is of opinion, that the Heart is the originall of the Nerves; for his Flesh is hard, thight and some-what membranous; but the Ventricles thereof haue in them infinite textures of manifest Sinewes.

Finally, the Heart is the first *αὐτοσκοπικὸν*, the first *ζῳτικόν* and the first *κινητικὸν καὶ ἐκσπικτικόν*, that is, *Sanguifier, Liuer, Mouer and Sensor*. That it is the first Sanguifier or the Workhouse wherein the Blood is made, the Philosopher demonstrateth; because in it the Blood is contained as in a Vessell or conceptacle and receptacle; whereas in the Liuer it remaineth but as in a Pipe or conueyance; and beside, no where in the whole Body is the Blood contained out of his Vessels, saue onely in the Heart, which therefore is the Treasure thereof; and therefore in all suddaine passions of the mind, it returneth and flyeth to the Heart, as to the Fountaine, not to the Liuer or to the Braine.

That it is *Primum sensorium*, the first sensor (that is) that the faculties of sense, motion and appetite, are deriued from the Heart, the *Peripateticks* proue by these Arguments. Because in a *Syncope*, that is, a swoounding where the vitall spirits faile, there appeareth a suddaine and head-strong ruine and decay of all the faculties. Because in all suddaine motions and approaches of noysome and hurtfull things, as also when we would auoid them, the heat of the Heart being drawne inward, there appeareth a pale wannesse in the Face; and on the contrarie, when we conceiue ioy for any thing that is profitable, or when we pursue such things, the heat of the Heart being called outward, there appeareth in the countenance a ruddinesse and alacritie. Because if the Arteries called *Carotides* be tyed or obstructed, then followeth presently a senselesse dulnesse, and a priuation of the Animalitie, if I may so speake, the Patient lying like a senselesse Stocke. Because Ioy, Sorrow and Hope, are motions of the Heart, in which consisteth all the Appetite we haue to pursue that which we like, or to flye and auoid that we dislike and abhorre. Finally, because in sleepe the Animall faculties doe rest and cease from their labors: Now sleepe is nothing else but a retraction or calling backe of the heat to the Heart from the other parts wherein it was in continuall expence; and that is the reason why a Man after sleepe is so much refreshed, and riseth strong againe to the labor either of Mind or Body, albeit in both he were well wearied, yea tyred out before. As for the Braine (they say) it cannot be the Author of Sense, because it is of a cold temper, vnapt for motion, and made onely to refrigerate and coole the exceeding heat of the Heart, being of it selfe without all sense. These and such like are the Arguments of the *Peripateticks*, by which they perswade themselves, that there is but one Principle of Mans body, which is the Heart.

But these conceits of Aristotle and the Philosophers, are long since hissed out of the Schooles of the Physitians, and banished from amongst them; because they assume those things for true which are vtterly false, and obtrude things probable as if they were necessarie. And what I pray you is more absurd, then to preferre the probabilitie of a Logicall argumentation, before the euidence of Sense, Reason and Experience, ioyned together? Now that the Veines doe arise from the Liuer, that the Nerves or Sinews which are soft and medullous or marrowy within, and without cloathed with Membranes, are deriued from the substance of the Braine, he that hath but one Eye may cleerely discerne. That great Philosopher obserued in the Heart many Fibrous strings in both his Ventricles, wouen out of the extremities of the small Membranes, and mistooke them for thready Nerves; whereas indeed it hath but one small Nerve arising from the sixth coniugation of the Braine, which looseth it selfe in his substance. He saw the hollow veine in the Heart verie large and ample; but he did not obserue, that it onely openeth into the Heart; (gaping at it with a spacious Orifice or mouth) to poure into the right Ventricle, as it were into a Cisterne, sufficient Blood for the generation of Vitall spirits, to supply the expence of the whole Body, but goeth not out of the Heart; as doeth manifestly appeare by those three forked Membranes, or Valves and Flood-gates, yawning outward, but close inward. But because we shall haue fitter occasion hereafter to dispute this Question with them, of the originall of the Veines and the Sinewes, it shall be sufficient that we haue said thus much of it at this time.

As for the Seat of the Faculties of Sense and Motion, is it not against all reason and experience,

experience, to place them in the Heart? The Heart indeed is moued, and that perpetually; but that motion is not voluntarie but naturall; it is moued, yet not at our pleasure, but according to it owne instinct. Daily practise and experience teacheth vs, that when the Ventricles of the Braine, are either compressed or filled and stuffed vp, as in the Apoplexy, Epilepsie and drowfie *Caros*, then all the Faculties are respited and cease from their functions; but when the Heart is offended, the life indeed is indangered, but neither Motion nor Sense intercepted.

That the Heart is not the beginning of Animall motion.

Againe, If the Heart were the Seat of all the Faculties, as the *Peripateticks* would faine haue it, then vpon any affection of the same, or notable deprauation of his temperament, all the functions should be impeached; because all actions come from the Temper. But we see that in a *Hectique* Ague or Consumption, wherein there is an vtter alienation of the Temper (as being an equall distemper, of all distempers the most dangerous) yet the voluntarie and principall Faculties, doe remaine inuiolate. In the violent motions, and throbbing palpitations of the Heart, which (some say) haue been scene so extreme that a Ribbe hath bene broken therewith, yet neither the voluntarie motions of the parts are depraued, nor the mind at all alienated or troubled. Who will deny, but that by pestilent and contagious vapors and breaths, comming from the byting of venomous Beasts, or the taking of Poyson, the Vitall facultie is oppugned, and as it were besieged in his owne Fortresse? But yet those that are so affected, doe enioy both sense and motion, euen to the last breath most times. When the Braine is refrigerated, sleepe presently stealeth vpon vs: Now *Aristotle* himselfe defineth sleepe to be *ἡρεσις τῆς πρώτης αἰσθητικῆς*, *The rest of the first sensator*. If any of the principall Faculties, either Motiue or Sensatiue be affected, where doe the remedies applyed auaille? Surely at the Head, not at the Heart. The Braine therefore, not the Heart, is the first Moouer, and first Sensator.

An elegant argument against the *Peripateticks*.

Strange motions of the Heart.

Aristotle.

But the *Peripateticks* obiekt that the Braine hath no sense, and therefore cannot be the Author of it. We will giue them a learned answer out of *Galen*, *The Braines sensation is not παθητικὴς, but ενεργητικὸς*, that is, not passiuely, but operatiuely. It receiueh not the Species or Images of sensible things; but like a Iudge, it taketh knowledge of their impressions, and accordingly determineth of them. They say, the Braine is vnapt for motion, because it is cold. We answer, It was necessarie it should be cold, that is, lesse hot, for the better performance of the functions. But if the Braine had exceeded in heat, then would his motions haue bene rash and vnruely, and his sensations giddy and fond as in a phrensie. In a *Syncope* the Animall faculties doe faile. It is true, but why? Because there is an exolution, and so a defect of Vitall spirits, by which the Animall are cherished. The ligation or interception in like manner of the Arteries of the Necke, called *Carotides*, induceth a priuation of motion and sense, onely because the Vitall spirits are intercepted, which minister matter to the Animall.

The sensation of the Braine not passive but operative.

Why the braine is cold, that is, lesse hot. Answers to the arguments of the *Peripateticks*.

But one Principle is better then many. That we confesse is verie true; but yet we know there are many reasons why it is not possible it should be so in this Little world. We will instance but in a few. It is granted by all Men, that the substance of the Arteries is diuers from that of the Veines; and the substance of the Sinews differing from them both; and as is their substance, so is their structure verie different, and their temper not one and the same: How then could it be, that Organs of so distinct kinds, should issue all from one and the same part? Againe, it was necessarie that these Organs should in their originall be verie large and ample to transfuse sufficient Spirits, and a common matter suddainly and together-ward into the whole Body. Now the magnitude or proportion of any one part (much lesse of the Heart) could not be sufficient for this purpose, either to afford a foundation for so large Vessels, or to supply a competent allowance of matter for them all. Adde hereto, that the Faculties of the Soule, follow the Temper of the Body, and therefore so diuers faculties might not issue from one part, which hath but one single temperament. How can we imagine reasonably, that three distinct and different Faculties, yea oftentimes quite contrarie, Reason, Anger and Concupiscence should reside altogether, as if they were sworne friends in one Organ? Or how when the Heart is on fire with Anger, should Reason make resistance, which delighteth in a middle and equall temper? Doe not the Vitall and Animall faculties require a different temper? Their Organs therefore must also necessarily be different and distinct. For the Heart is by Nature fitted to containe and propagate the Vitall facultie; but for the preservation of the Animall, it is vtterly incompetent. The reason is at hand. The Vitall spirit is verie hot, impetuous, raging,

Why in the Little world there cannot be onely one Principle. The first demonstration

The second.

The third

The fourth.

and in continuall motion, and therefore stood in need of a strong Organ wherein it should be wrought and contained, that the Spirit might not because of his tenuitie, be exhaled, nor the Vessell by which it is conueyed, breake in perpetuall pulsing and palpitation; which both would easily haue hapned, if the Heart and Arteries had beene thin, and of a slender texture. The Animall facultie required another temper in her Organ, otherwise the Motions would haue beene furious, the Senses giddy and rash; Reason would continually haue erred, because the propertie of heat, is to confound and make a medley of all things, shuffling in one thing huddlingly vpon another, through his continuall & indefinent motion. And these are the Arguments whereby the opinion of the *Peripateticks* is expelled out of the Schoole of the Physitians.

How *Auicen* interpreteth *Aristotle*.

Auicen, *Fen prima primi, doctrina* 5. cap. 1. interpreteth *Aristotles* opinion, playing the stickler in this manner. All the Faculties (saith he) doe reside in the Heart, as in their first Root, but yet they shine in the other Members, that is, the Heart is the originall of diuers Faculties, but vseth the Braine as the Instrument of Sense, so that *Radically* (that is his word) the Animall facultie is in the Heart, but by *manifestation* in the Braine.

The opinion of some later writers, and their diuers distinctions.

Some againe intercede for the *Peripateticks*, and say, That the principall Faculties, motiue and sensitiue, are in the Heart, as in their originall and fountaine. That the Roots of the Nerues are in the Heart, but because it is too narrow to yeeld out of it selfe all their propagations, they thinke the Braine was framed as a second Principle, wherein the Animall functions might, not obscurely as in the Heart, but evidently manifest and exhibite themselves. And this Power or Facultie when the Braine hath once receiued it from the Heart, standeth in no need of continuall and immediate assistance there-from, but onely of a supply after some time: Euen as the Commander of an Army, who hauing receiued his Authoritie and his Companie from the Prince, standeth in no farther need of the Princes protection, vnlesse it be now and then vpon especiall seruices. They conclude therefore, that the Braine and the Liuer are truly called Principall parts; but this principallitie is but delegatorie from the Heart, no otherwaies then the Lieutenants of Princes, by them chosen for such and such employments, doe receiue from them an order and power of dispensation and disposition, whereby they are authorized, and so taken, as if they were immediate Commanders themselves. Some others vse an other distinction, and say that materially the Nerues proceed from the Braine, and the Veines from the Liuer; but the first and the formall Principle they say is in the Heart.

Comparison

Scaligers opinion.

That Prince of humane Learning (at least, he that affected that Soueraigntie) *Iulius Caesar Scaliger*, in the 289 Exercise of his Booke *De Subtilitate*, maketh many principles in the Heart. The first or primarie is τὸ ζῶν or the living: The secundarie τὸ κινητικόν or the mouing Principle: These doe neuer cease, neither are they hindered or intercepted in our sleepe or repose: Yet are they not τὰ πρῶτα ἀιδιτικὰ tamet si τὸ πρῶτον ἀιδισιμὸν, that is, they are not the first *Sensators*, though they be of or from the first *Sensator*. Thus learned Men labor to reconcile the *Peripateticks* and the Physitians. But they seeme not to hold themselves close to *Aristotles* meaning: For he doth not thinke that in any sense, the Braine can be said to be the Author or originall of Sensation, neither that the Nerues doe arise from it. No where doth he attribute any delegatorie power of Sensation vnto it; but thinketh it was onely made to refrigerate or coole the heat of the Heart; whereas, notwithstanding all he can produce, it is the first Principle of Sense and motion, neither receiue any power for the performance of either of them from the Heart.

The late writers did not vnderstand *Aristotle* well.

The opinion of the *Arabians* confuted.

And whereas the *Arabians* say, that the Animall facultie is *radically* in the Heart, and but by *manifestation* in the Braine; we can no way admit of that distinction: For if that Facultie were in the Heart as in the Root, then when the Braine is obstructed, the Body should not become senselesse and without motion, because there should be a remainder both of Sense and Motion in the Root, that is, in the Heart. But though the Heart be obstructed, or the passages intercepted betweene it and the Braine, yet there followeth not any suddaine priuation of Sense and Motion. Instances hereof we haue in Sacrifices, where the Beast some-times hath beene heard to cry, and some-times also seene to run a little while after his Heart hath beene cut out: And we haue seene the same tryed in a Dogge, which ran crying a while after his Heart was cut out, the Vessels arising from it vpward, being before bound.

Sacrifices run from the Altar without their Hearts.

Galen elegant demonstration

Galen in his first Booke *De Placitis*, illustrateth the whole matter, by an elegant demonstration. If the Heart (saith he) did giue vnto the Braine the Animall facultie, then should

that

that power be deriued either by Veines, Arteries or Sinewes; for there are no other Vessels which goe betweene them, and are common to them both. By Veines or Arteries *Aristotle* himselfe doth not thinke it is conueyed; besides, these Vessels doe not directly passe vnto the Braine, but after diuers contorsions and aberrations from a right and direct progresse. That it is not deriued by or through the Nerues is manifest; because, if the Nerue which is disseminated through the substance of the Heart, be either diuided and cut asunder or intercepted, yet the Creature doth not presently fall, but onely groweth mute and dumbe.

It is therefore more consonant to right reason, that seeing the Soule is but one and a simple substance, and wholly in the whole, and wholly in euerie Particell of the Body; and therefore must necessarily haue the helpe of Organs for the accomplishing of her seuerall functions: to assigne the Seat of the Facultie there where the Organs of those Faculties are especially to be discerned. Wherefore seeing the *Peripatericks* doe confesse, that the Organs of Sense and Motion are more conspicuous in the Braine then in the Heart: why will they not yeeld to the Physitian, that the Animall facultie is in the Braine, the Vitall in the Heart, and the Naturall in the Liuer; but make all the world witnesses of their refractarie minds, then which in a true Philosopher nothing is more illiberall? Howloeuver to conclude, we subscribe to the opinion of the Physitians, who haue banished this Vnitie of Principles out of their Schooles.

The conclusion of the whole disputation.

QVEST. III.

How many Principall parts there are.

BY those things which we haue thus at large discoursed, it is manifest to all Men, that there is not one, but many Principall parts of Mans body; it remaineth that we shew you now how many there are. The number we cannot better apportion, then from the nature and definition of a Principle. First therefore, we must make it appeare (because Physitians herein doe not agree) what a Principall part is.

Galen in his Booke *De Vsu Partium*, defineth this Principallitie by Necessitie. That is a Principall part, which is of absolute necessitie for the life of Man. I will shew you (saith he) by what markes you shall know a Principall part, to wit, by the profit it brings; now the profit of a Part is three-fold, either it is simply for life, or for better life, or else for the preservation of them both; and all such Parts without doubt, are truly Principall. And in the first Chapter of the fourteenth Booke *De Vsu Partium*, Nature hath a three-fold scope in the structure of the Parts of Mans body. The first is of those which are necessarie for life; and such Parts are called Principall, as the Braine, the Heart, and the Liuer, &c. We will therefore define a Principall part to be *that which is absolutely necessarie for the preservation of the whole individuum or particular Man.*

What a principall part is. *Galen.*

Argentarius, who in a humor of contradicting *Galen*, opposeth himselfe vnto him, reiecteth this definition; because if a Principall part be defined by necessitie, the Stomacke, the Loynes, the Spleene, the Bladder and the Kidneys, will all fall into the reckoning of Principall parts. For the Action of the Stomacke is necessarie also for life. The Motion of the Lungs we cannot misse, no not for a moment of time; the interception of the Vrine is mortall; and therefore the excretion or auoiding thereof, which is accomplished by the Kidneys and the Bladder is necessarie. But he seemeth to me not to haue attained to the thorough vnderstanding of *Galen*'s mind: For there is a double necessitie of the Parts; one absolute for the preservation of the *individuum*, another not *absolutum*, that is, simply and absolutely, but *secundum quid*, or hauing reference to the former. The first maketh a Part principall, as the Braine, the Heart, and the Liuer: The second kind of necessitie, is but relatiue or collaterall, by which some Parts owe obseruance to the Principall, as necessarie seruitors vnto them. For example: What necessarie and immediate offices doe the Lungs, the Kidneys, the Bladder and the Spleene performe to the Arme, the Legge, or the Stomacke? But the Heart giueth them Life, the Liuer affordeth Nourishment, and the Braine supplyeth them with Sense and Motion.

The first definition of principallitie.

Argentarius his vaine opposition to *Galen.*

Argentarius answered. A double necessitie of the parts.

This may seeme some-what obscure to those that are but Catechists in our Art, but by examples we shall make it sufficiently perspicuous. The Liuer is the onely Prince in the lower

lower Region or Belly, being therein alone absolutely necessarie, and at his owne cost, nourishing the whole Family of the Body; all the other Parts within his Precinct are made for his vse. The Stomacke as a Seruant ministreth Meat vnto him; the Bladder of Gaull purgeth away the Choller from that Meat; the Spleene drayneth away the Melancholy Iuyce, and the Kidneys the serous or whayie Humor: all concurring to depure and cleanse it from Excrements to his hand. If therefore they be necessarie, it is not for the preservation of the whole Man, but because they be necessarie Ministers to assist the Liuer in his worke. Againe, the Heart sitteth in the middle Region as in his Palace, the Lungs, the Midriffe, and all the Arteries attending him for his vse, whom he employeth in quickning the whole Body; the same may be said of the Braine. Wherefore the Braine, the Heart and the Liuer, are onely Principall parts, because they alone are immediately and absolutely necessarie for the preservation of euerie particular Creature. *Galen* also answereth this cauill another way, on this manner. The action of the Stomacke is not absolutely necessarie, but onely for the continuance and prorogation of life. Witnesse those Creatures which mew themselves vp all Winter, neuer eating, and so not vsing the action of the Stomacke, albeit they liue nathelesse. Furthermore, nourishing Clifters doe not ascend vnto the Stomack, yet they are sucked by the Meseraick-veines, & transported vnto the Liuer, and so sustaine the Body, as may be instanced in that Malefactor, who after he was taken from the Gallows, was found to be aliue, and a good while sustained by such Clifters, when it was not possible to get any thing into his Stomacke. A Creature therefore may for a time liue without Chilification, which is the action of the Stomacke, but not without Sanguification, saith *Galen*, which is the proper function of the Liuer.

That which is obruded concerning the Lungs, is of no moment; for they worke rather for the commoditie of the Heart, then for the immediate maintenance of life. The Heart might satisfie it selfe with Aire attracted through the rough and smooth Arteries; but lest the outward impuritie thereof suddainly rushing into the Ventricles should offend it, Nature hath cautelously set the Lungs betweene them, as a Shoppe wherein the Aire is broken and dulcified before it come vnto the Heart. And thus much may suffice to satisfie the former obiection, and to euince that onely those parts are principall, which are absolutely and immediately necessarie for the preservation of life.

But there are others which oppose *Galen* to *Galen*, who in the first Chapter of his first Booke *De Locis Affectis*, affirmeth, that the Heart onely is absolutely necessarie for the life of the Creature: His words are these, *If the Creature be neither nourished, nor haue sense or motion (which hapneth in such as lye within the Earth) yet may it liue as long as the Heart is not violated; but if the Heart be defrauded of respiration, the Creature instantly perisheth.* To this we answer: That in bloody and perfect Creatures, the action of the Braine and the Liuer, are absolutely necessarie; but those Creatures which liue so mewed vp in Winter, are vnbloody or without Blood, although it cannot be denyed, that Hysterically women, that is, such as haue violent fits of the Mother, doe liue some good space without breathing, as we could instance in many, if it were not so ordinarie, as that no Man will deny it, but they haue the vse of Transpiration.

There is also another very elegant definition of a Principle, in the tenth Chapter of *Galen*s sixth Booke *De Placitis*, in these words: *That is called a Principall part, which alloweth or affordeth to the whole, either some Facultie, or at least some Matter.* According to this definition also, there will be three Principall parts. For that the Braine doth transmit the Animall facultie, and the Heart the Vitall, will be easily yeelded vnto vs. All the scruple is about the Liuer, because it seemeth not reasonable, that it should afford to the particular parts, a naturall influent Facultie, seeing euerie part hath such an one bred, and seated in it selfe. For the time we let passe that Controuersie, it is sufficient for our present purpose, to proue it a Principall part, though it yeeld no Facultie, if it yeeld a Matter to the whole Body, which no Man in his right wits but will easily confesse, or let him but pricke his Finger and he shall see it.

Aniceti *Fen 1. Doct. 5. Cap. 1.* defines that to be a Principall part, which hath in it selfe the Originall or beginning of the first and chiefe Faculties of the Body; or wherein the power or efficacie of those Faculties, by which the Body is dispensed or gouerned, doth as in his chiefe Seat especially reside and manifest it selfe. Some of the late Writers haue defined a Principall part to be that, which out of it selfe exhibiteth and communiceth to other parts some active Instrument; as for instance, a Spirit. So that which of all these definitions

definitions we accept of, it will still remaine that there are three Principall parts, the Braine, the Heart, and the Liuer. For if we respect Necessitie, these onely are absolutely necessarie; if the Originall of the Faculties, in the Braine resideth and shineth the Animall, the Vitall in the Heart, and the Naturall in the Liuer; if the Instruments, then from the Braine floweth the Animall spirits by the Sinewes, the Vitall from the Heart by the Arteries, the Naturall from the Liuer by the Veines; and by those passages are all diffused from their Fountaines into the whole Body.

Galen in his Booke *De Arte Parua*, addeth to the Principall parts a fourth, to wit, the Testicles: Not in respect to the *indivium* or particular Creature, but because they are of absolute necessitie for the conseruation of the kind, and production of increase. For the Testicles indeed doe not make allowance to the whole Body of any Matter, or Facultie, or Spirit, but onely of a Qualitie, together with a subtile and thin breath or aire, from which the Flesh hath a ranke tast of the Seed, and the Body a strength or farther abilitie in the performance of his actions.

QVEST. IIII.

Which of all the Principall parts is the most noble.

Having præmised this Disputation concerning the number of the Principall parts, it remaineth (because we would haue nothing wanting which may giue satisfaction to such as desire it) that we enquire which of all the Principall parts is worthily to be preferred aboue the rest. Galen in his first Booke *De Semine*, preferreth the Testicles to the Heart; where he saith: *The Heart is indeed the Author of liuing; but the Testicles are they which adde a betternesse or farther degree of perfection to the life*, because if they be taken away, the iollitie and courage of the Creature is extinguished; the Male followeth not his Female, the Veines loose their Latitude, and become sunke and narrow; the Pulse abateth of his strength, & becomes weake, dull & languishing; the Skin is pild and bare, whereupon such Men are called *Glabriones*; and in a word, all Virilitie or Manhood vanisheth away. Galen addeth: The Testicles are another Fountaine or Well-spring of in-bred heat; the Feu-place or Fire-hearth, where the *Lares* or Household-Gods of the Body, doe solace and disport themselves: From hence the whole Body receiueth an increase of heat, and by that meanes not onely Fœcunditie, but also a great alteration of the Temper, the Habit, the proper Substance, yea and of the manners themselves: So that to say true, their power is verie great, and almost incredible, then especially knowne when it is wanting, as we may obserue in Eunuches.

Wherefore as to be and liue well, is more excellent then simply to liue and haue an Idle and sluggish existence, so the Instrument of the former which is the Testicles, is more excellent then that of the later, which is the Heart. A probable but a sophisticall argument. True it is, that which giueth better life, if it giue life also, is more excellent then that which giueth life onely: But the Testicles doe not giue life at all, the Creature can liue without them; they adde indeed a perfection, not to life, that is, to the concrete as we say, but to liuing, that is, to the abstract; so doe the Eyes, so doe other parts, without which a Man should liue, but in liuing should be miserable: The Heart therefore giueth the Substance, the Testicles exhibit but an additament, which may be away, albeit it be with notable detriment; detriment I say, not of that which the Heart giueth, which is the Substance; but of that which themselves afford, which is a Complement. Now that a Substance is of more excellence then a Complement no Man will deny, the Heart therefore is more noble then the Testicles. But the Heart hath a greater concurrent in this plea of Honor, which is the Braine.

The *Peripateticks* and *Aristotle* their Prince, together with the whole Family almost of the *Stoicks*, especially *Chrysippus*, doe giue the preheminance to the Heart, as well because it is seated in the middest, which is the place of Honor; as also because it is a liuing and abundant Fountaine of natiue heat; and finally, because it is the speciall habitation of the Soule; for euen *Hippocrates* himselfe, the Oracle of Physicke, in his Booke *De Corde*, placeth the Soule in the left Ventricle of the Heart; and hence it is, that they call the

Heart

Galen protesteth the Testicles before the Heart

Glabriones Galen.

Wherein the Testicles doe shew their power.

principal part

An elegant
demonstrati-
on how all
the body is
serviceable to
the braine.

But all this notwithstanding, we are enforced to yeeld the superioritie to the Braine, because his functions are more diuine and more noble then those of the Heart. For example: All sense and voluntarie motion proceed from it, the Habitation it is of Wifedome, the Shrine of Memorie, Iudgement and Discourse, which are the prerogatiues of Man aboue all other Creatures. This is the Prince of the Family, and the Head is the Head of the Tribe, all other parts are but attendants (though some serue in more honorable place then others) and owe homage vnto it, yea all were created onely for his vse and behoofe. For the Braine being the seat of the intelligible or vnderstanding Facultie, it was requisite first, that it should be supplied with phantasmes or representations; these representations could not be exhibited and represented to the vnderstanding, but by the ministry of the outward senses. For it is a rule in Philosophy, *Nihil est in intellectu quod non prius fuit in sensu. There is nothing in the vnderstanding or intellect which is not first in the sense.* It was necessarie therefore, that the Senses should be created for the Intellect. Furthermore, the Senses could not haue been perfect vnlesse the Creature could haue moued locally to gather his phantasmes out of diuers obiects, as the Bee flyeth from one Flower to another to gather Honey; and therefore Nature ordained the Organs or Instruments of motion, the Muscles, the Tendons and the Nerues. These (vnlesse we should haue crawled vpon the Earth like Wormes) did necessarily require props and supporters to confirme and establish them, whereupon the Bones & the Gristles were ordained; and Ligaments also to knit and swath them together: Now all of them stand in need of perpetuall influence, of heat to quicken them, and of nourishment to sustaine them; both which are supplied, the former from the Heart by the Arteries, the latter from the Liver by the Veines: So that truth to say, there was no other end of the Creation of all the parts and powers of the Body, but onely for the vse and behoofe of the Braine.

Obiection:

Answer.

It will be objected, that the Braine cannot accomplish his functions without the spirits of the Heart, and the influence of his heat. I answer, that that is an inuincible argument of the soueraigntie of the Braine; for the end for which a thing is ordained, is more noble then the thing ordained for that end; the Life therefore & the Heart are but Hand-maids to the Braine. We will adde also this argument, which haply will seeme not incompetent. The Braine giueth Figure vnto the whole Body; for the Head was made onely for the Braine; now *Hippocrates* saith, that the nature of all the rest of the Bones dependeth vpon the magnitude of the Head: Not that all the Bones deriue their originall from the Head; but because it behooueth that they should be all proportionably answerable to the Bones to which they are articulated, as the Legs to the Thighes, the Thighes to the Haunches, the Haunches to the Holy-bone, the Holy-bone to the Spondels or Rack-bones, the Rack-bones to the Marrow of the Backe, and that to the Braine.

A rule in the
disposition of
the parts.

Galen

For satisfaction to the Arguments before vrged by the *Peripatetians* and the *Stoicks*, we say, That the *Etymon* or deriuation of the name of the Heart, is but friuolous and not worthy the standing vpon. For the scite of the Heart in the midst, it doth weigh *tantumdem*, as much as nothing; neither indeed is the ground of it true: For of the whole Body, the Nauell is the Center; and for the Trunke or bulke, who euer said (that was an Anatomist) the Heart was in the mid'st of it? But if we will draw an Argument of dignity from the scituation, then will the true superioritie fall to the Braine, because it is placed vppermost, as the Fire aboue the inferiour Elements; the highest Heauen the seat of the blessed Soules, aboue the subiected Orbes; for to be placed aboue, is high superioritie and preheminance; to be thrust downe below, betokeneth base subiection & inferiority. As for that place of *Hippocrates*, where he placeth the Soule in the left Ventricle of the Heart, either he speaketh to the capacitie of the vulgar, or else by the Soule he meaneth the heat, as haply we shall haue more occasion to shew hereafter. We conclude therefore, that of the principall parts, the first place belongeth to the braine, the next to the heart, the last to the liuer. Again, in the *Oeconomie* or order of the parts, this rule is obserued; that those which are first in order of nature, are last in dignity & excellency: So the Infant first liueth the life of a plant, then like a beast it moueth and becommeth sensible; finally, it receiueth it's perfection when it is indued with the reasonable soule; as hauing then the last hand and consummation from the Creator, when he setteth his Stampe or Image vpon it.

Galen in the last Chapter of the seuenth Booke of his Method, compareth the dignitie and

and necessitie of the three principall parts one with another in these words: *The dignitie of the Heart is verie great, and in sicke Patients his action and the strength of it, of absolute necessitie; the Braine is of equall moment for the preservation of life, yet the strength of his actions is not so immediately necessarie in those that are diseased, for their recoverie; the action of the Liuer is as necessarie as either of them for the maintenance of the particular parts, but yet for present and immediate sustentation of life, it is not so instantly necessarie as both the former.* To conclude this question, there is a three-fold principle; one of Beginning, another of Dignitie, a third of necessitie. The *Parenchyma* or Flesh of the Liuer is the originall principle; the Braine is the most noble principle; and the Heart of most necessitie; yet they all haue such a mutuall connexion and conspiration, that each needeth others assistance, and if one of them decay, the rest doe forth-with perish. Euen as in a well-gouerned Citie or Common wealth there is a wise Senate to guide it, a stout and valorous strength of Souldiers to defend and redeeme it, and an infinite multiplicitie of Trades and Occupations to maintaine and support it; all which though they be distinguished in Offices and Place, doe yet consent in one, and conspire together for their mutuall preservation. And this conspiration *Galen* expresth to the life, in his Booke *De Formatione Fetus*, and the fifth Chapter, thus: *When the Heart is deprived of respiration it ceaseth to moue, and immediately death insueth; now it is deprived of respiration when the Nerves (which come from the Braine) are either cut, or obstructed, or intercepted.* As therefore the Heart needeth the helpe of the Braine, and being forsaken by it, maketh a diuorce between the Soule & the Body; so it also maketh retribution to the Braine, supplying it with Spirits of life, out of which the Animall Spirits of the Braine are extracted; and the Liuer though it lye below, yet it yeeldeth matter to them both, whereof and whereby their Spirits are made and sustained.

But against this doctrine of the consent of these principall parts, there is a notable place of *Galen*, in the fourth Chapter of his second Booke *De Placitis*, which needeth to be cleared before we fall from this discourse; for he saith: *As Pulsation and voluntarie motion belong to diuers kinds of motion; so neither of these principles needeth the helpe one of another.* Which place we interpret thus: That the Heart doth not transmit the Animall facultie to the Braine, nor the Braine the facultie of Pulsation to the Heart, because the Temper and Formes of the Faculties are diuers; and therefore the Heart conferreth nothing to the *Idea* or Forme of voluntarie motion, neither the Braine to the power of Pulsation; yet hence it must not be inferred, that the Braine needeth not the helpe of the Heart, or on the contrarie, the Heart of the Braine: And thus much of the definition, and number, and precedencie of the principall parts.

QUEST. V.

Of Similar and Dissimilar parts, and first of the number of them.

THe nature and number of the Similar parts because they are much controuerted, we will examine for their sakes, who are not so well exercised in these Schoole-points; that if they be not able to draw out of the Fountaines themselves, they may dip their Vessels in this shallow Ford of ours, to satisfie their thirstie minds.

Some there be that contend, that there are no Similar parts at all, because the most simple are not void of composition; and they alleage *Galen*'s authoritie for it; who in the eighth Chapter of his first Booke *De Elementis*, saith: *That the simple parts are made of Humors, Humors of Aliments, Aliments of Elements.* And in his first Booke *De Semine*, *All parts are generated of Seed and Blood.* But the answer to this is easie and obuious; for parts are called Similar, not because they are exquisitely simple and uncompounded, but because they cannot be diuided into *Parts* of diuers kinds, neither yet are compounded of any other *Parts*, though they be of diuers substances. So the Philosopher calleth the Elements simple Bodies, because they are not compounded of other *Bodies*, although they consist of Matter and Forme. Yea the verie Soule of Man is not in this sense truly simple, nor yet the Angelicall substance; for if they were, they should be inpatible; And indeed nothing is truly simple but God himselfe; but we of purpose giue ouer this mysterie before we enter into it, because every one is not a fit Auditor of this kind of Philosophy. The number of

of the Similar particles concerneth vs at this time more, wherein there is great heat and contention of opinions. *Galen* in his Commentaries vpon *Hippocrates* Booke *De Natura Hominis* numbred seven: *Bones, Gristles, Ligaments, Membranes, Fibres, Fat and Flesh*. And whereas there is a threefold kind of Flesh, one of the Muscles which is indeed true Flesh, another of the Entrails which is called *πασιχυμα*, and the last of the particular parts; he accounteth them all Similar, for so he speaketh in the sixth Chapter of his first Booke *De Naturalibus Facultatibus*. Among the Similar parts are to be accounted the Flesh of the Liver, the Spleene, the Kidneys, the Lungs and the Heart; as also the Coates of the Stomach and the Guts, and the proper body of the Braine. For if from all of these you shall exempt or take away, either really or in your imagination, the Veines, the Arteries and the Nerues; the Body which remaineth will be Simple & Elementarie. In the sixth Chapter of the first Booke *De Elementis*, he addeth to the former seven, *Sinews, Marrow, Nails and Haire*. In his Booke *De Inaequali Intemperie*, *Tendons* and *Skin*. In his Booke *De Differentijs Morborum*, and in the second Booke *De Elementis*, he addeth *Veines* and *Arteries*. So that according to *Galen* in the places alleaged, if we summe vp the Similar parts, they will arise to fourteene: *Bones, Gristles, Ligaments, Membranes, Fibres, Nerues, Arteries, Veines, Flesh, Skin, Fat, Marrow, Nails and Haire*.

Many accuse *Galen* of leuitie and forgetfulness, because in diuers places he calleth Veines, Arteries and Nerues Similar parts; and yet in his Booke *De Inaequali Intemperie*, he accounteth them Dissimilar and Organicall. *Argenterius* answers for him; That in a Similar part, he hath a double respect to their Matter and their Forme; and whereas he calleth Nerues, Veines and Arteries, Similar Bodies, he doth it with respect to their Matter, which is simple & vniforme; where he calleth them Organicall, he hath respect to their Forme and Figure, which is round and more or lesse hollow. But *Argenterius* by this answer, rather betrayeth then redeemeth his Master: For the matter of the Veines, Nerues and Arteries, is not vniforme. *Galen* in his Booke *De Placitis* and *De Vsu Partium*, teacheth that Nerues are withinward soft and marrowy, outward membranous; as also the bodies of Arteries are woven of Membranes and Fibres.

The common and vulgar answer for *Galen*, we rather approue, which is after this sort: There are two kinds of Similar parts, some are so in truth, as *Bones, Gristles, &c.* others Similar to the iudgement of the Eye, such are Veines, Arteries and Nerues; because at the first view when we cast our Eye vpon them, we perceiue an vniformitie in their substance. But some Man will vrge farther, that euen in the iudgement of the Eye, those three Vessels aboue named, are not simple but compounded; for our Eye bewrayeth the in-side of the Nerue to be Medullous, and the out-side Membranous. And *Galen* in the sixth Chapter of his first Booke *De Naturalibus Facultatibus*, saith: That Similar particles are by no other meanes to be discerned, but by Dissection and Autopsia: that is, by the Eye of the Anatomist. This scruple *Montanus* thus remoueth: There is, saith he, a double Anatomy, one most exquisite and artificiall, another more rude according to the times wherein *Hippocrates, Diocles* and *Erasistratus* lived, when the Art was in her infancie: And to these times, the Nerues, Veines and Arteries seemed at the first sight Similar parts, albeit since as the Art hath gathered strength, and Men growne more oculte priers into the Nature and Frame of the Body, there hath been some difference discerned.

It will be further obiected, that there are more Similar parts then *Galen* and the Schoole of Physitians haue described. For the Marrow or substance of the Braine, the Christalline humor of the Eye, the Pith of the Backe, as also the other humors of the Eye are truly and in the nicest construction Similar parts. We may answer, that all these are indeed truly Similar, but yet they all concur to the frame of one part; but *Galen* spake onely of those Similars, of which as of sensible and common Elements, many Dissimilars were compounded.

QUEST. VI.

Whether a Similar part may be called Organicall; and whether the actions belong to the Similar parts, or to the Organicall.

According to the Doctrine of *Aristotle* and *Galen*, a Dissimilar and an Organicall part are not distinguished. But because according to the same *Galen*, the Essence of an Organicall part consisteth onely in the conformation, that is, a conuenient Figure,

Figure, Magnitude, Number and Scituation, all which are found also in Similar parts; I am easily perswaded to be of the opinion of some of the late Writers, who thinke that Similar particles, may also be called Organically, and therefore that the Dissimilar is better opposed to a Similar, and to an Organically a rude and vnformed part. Neither doe I thinke, that *Galen* was hereof ignorant; but because the varietie of Composition, and the neatnesse of the Figure was more conspicuous in those that are Dissimilar (the Similar being vniforme) he pleaseth to call them absolutely and by an excellence, Organically. So the Philosopher in his first Booke *De Ortu & interitu*, calleth the Head, the Chest, and the Belly, principall Organs, because the most irresolute Scepticke, cannot but acknowledge their action and diuerse composition.

Some vntie this knot on this manner. An Organically part is to be considered either as it is figured, or as it performeth some Organically action. In the first respect, almost all Similar parts are Organically; for euen the Bones haue a proper Figure, Magnitude, Number and Scite. In the second onely Dissimilar, because these alone doe performe Organically actions. For who will affirme, that in a Bone there is any action Organically? It is true, that their Figure, Magnitude and Scite are of good vse, but they performe no action. Whereas the Veine and the Muscled, although of all Organs they are the most simple, doe performe each of them a manifest Organically action; the one distributing and dispersing the Blood, the other accomplishing voluntarie motion. But that these things may be more manifest, and descend deeper into the capacity of those that are but initiated, it shall not be amisse to recall them againe to the ballance, and weigh them ouer more precisely.

Galen in the sixth Chapter of the first Booke of his Method, and in his Booke *De Inaquali Intemperie*, defineth an Organ to be *that part of the Creature which can performe a perfect, that is, a proper action*. More fully it may be defined thus. *A part which onely produceth an action proper and peculiar vnto it selfe*; so a Muscled and an Eye are called Organs, because onely the Muscled moueth, the eye onely seeth. As for the Similar parts, their action is perfect indeed, but common, not proper or peculiar to themselves, to wit, Nutrition; and therefore they cannot properly be called Organs. Now that Nutrition is a Similar, and not Organically action, it appeareth by both their definitions. That action is said to be Similar, which is commenced or begun onely by the Temper of the Part, and by the same perfected; and is beside wholly and perfectly wrought by the least portion of the Part, as well as by the whole. That Nutrition is of that nature, it is so manifest, as it needeth no demonstration; for euerie part or portion of a Bone, draweth, retaineth, boyleth the Aliment; and beside, expelleth that which is superfluous; the reason is, because euerie part of a Bone is a Bone, and hath the forme and nature of the whole Bone: This forme is called *Temperies* or the Temper, wherefore onely from the Temper proceedeth the originall and perfection of Nutrition. Again, *Flesh* (as *Galen* saith in the ninth Chapter of the first Booke *De Vsu Partium*) is *Flesh onely through his temper, and a Nerue is a Nerue by his temper*. And in the first Booke *De Naturalibus Facultatibus*, He that indeauoureth to preserve the action of the Similar parts, it is necessarie that he preserve their Temper. So that it is manifest, that Nutrition accordeth with the definition of a Similar action. Now how repugnant it is to the definition of an Organically action, it remaineth that we shew. That is called an Organically action, which neither is begun, nor absolued or perfected by the Temper alone, but requireth to his integritie & perfection the whole Instrument. So vision, which is the proper action of the Eye, is not accomplished by the Christalline humor alone, nor alone by the Optick-nerue, or the coates of the Eye, but by all together. Neither is the forme of this organically action the temper, but the laudable conformation of the whole Instrument. The Eye seeth not, the Hand handleth not, the Foot goeth not forward, the Muscled moueth not onely by the Temper; but because the Organs are thus or thus disposed or framed.

Here some ouertaken with irresolution, because of the obscuritie of the Question, doe sweat and contend to proue, that all actions belong to the Similar parts & proceed from them, none from the Organically. And they alleage the authoritie of *Galen* for their warrant; who in the second Chapter of the seuenth Booke of his Method, and the third Chapter of the sixth Booke *De Locis Affectis*, and in his Booke *De Optimo Corporis Habitu*, saith, *That in euerie Organ there is one particle Similar, which is the principall cause of the Organically action, and that the rest are onely assistant, conferring some vse but no action*. So vision proceedeth from the Christalline humor, Sanguification from the *Parenchyma* of the Liuer, voluntarie motion from the *Flesh* of the Muscled; but the coates of the Eye, the Muscles,

A two-fold consideration of an organically part.

Galen's definition of an organ. Another.

What is a similar action

The forme of a similar part is his temper. *Galen*.

What is an organically action.

Whether the action doth proceed from the similar parts. Authorities of *Galen* to proue that they doe.

the Nerues, the two humors, do either make the Sight more perfect, or onely conferue it. Moreouer, in the fifth Chapter of his Booke *De Constitutione Artis*, he writeth, *That the action is primarily and per se, that is, of it selfe, from the Similar part; and secondarily, and by accident, from the Organicall.* Adde hereto that the Functions doe flow from the Faculties, the Faculties from the Temperament; now the Temper is the forme of the Similar part, not of the Organicall: And in the fifth Booke *De Locis Affectis*, he saith, *That the verie Essence of all the Faculties doth consist in the Temper.* In the sixth Booke *De Locis Affectis*, he saith, *That the Actions doe flow from the proper and peculiar Essence of the Parts, not from the Position: For if the Heart or the Liver should change their place, yet would they performe the actions they doe in the places wherein now they are.* And in the tenth Booke of his Method, speaking of a cold Bath: *Those that are Hellicall, that is, in a consuming and lingring Ague, are easily offended by the occursion or touch of cold water or Aire, because their Solid and Similar parts (they being more neere the Threds) are bare and naked, by which all the actions of living Creatures are performed.* Aristotle also is of opinion, that all sense commeth from the Similar parts.

Aristotle.

The explication of the question, wherein Galen is interpreted.

What we must resolve upon according to Galen.

This their deuce I must needs say is probable, but yet they trouble the pure Fountaine of Galens Philosophy. It is true, that he acknowledgeth in euerie perfect Organ one Similar particle, which is the principall cause of the action, but yet he neuer meant to referre the cause of the perfect action onely to the Temper of that Particle: So he acknowledgeth the Temper of the Christalline humor, to be the efficient cause of Vision or Sight, together with his Puritie, Smoothnesse and Scituation, which are all Organicall. For if the position of the Christalline humor be changed, if it be drowned too deepe in the glassie humour, although the Temper of it remaine neuer so exquisite, yet the vision cannot be perfect. In a word therefore I answer, that the originall of the action dependeth vpon the Similar part and his Temper, but the perfection of the action followeth the frame of the whole Organ. And this Galen teacheth in the sixth Chapter of his Booke *De Differentijs Morborum*, and in his Booke *De Optima Corporis Constitutione*, where he willet and resolueth, *That the actions doe first of all and originally issue from the Similar particles, but their accomplishment and perfection dependeth vpon the frame of the whole Organ.*

QUEST. VII.

Whether the Spermatieall parts be generated of Seed.

Three questions concerning spermatieall parts.

The first question.

The Peripateticks thinke that all the parts are generated of blood. The first Reason.

The second. Aristotle.

Having thus handled the distinction of the Parts, and the natures of them all; it remaineth that we entreat of those parts which are called Spermatieall; concerning which, there are three Questions among the rest most notable: Whether they be immediately made of the Seed; Whether they can grow together againe, or be restored, if their vnitie be dissolued; And whether they be hotter then the Sanguine or bloody parts or no; all which we will dispute in order. The first Question is hard to be determined, and therefore we must be constrained to take our rise a little higher, for that the nature of Seed which is intangled in many folds of difficulties, must first be vnfolded: Notwithstanding, because we shall haue fitter opportunitie in the Booke of the Generation of Man, to search more narrowly into the mysteries of this secret, we will content our selues in this place briefly to run ouer those things which shall most concerne the matter we haue in hand.

It is agreed vpon betweene the Physitians and the Peripateticks, that Seed is a Principle of Generation. But the Philosophers doe acknowledge it onely to be a formall and efficient Principle, the Physitians both a formall and a materiall; Formall, by reason of his Spirits; Materiall, by reason of his Body. The Physitians therefore doe determine, that the Spermatieall parts are generated out of the Crassament or thicke substance of the Seed, the Peripateticks, onely out of the Blood. This latter opinion is not without his Patrons & Abettors, and beside, supporteth it selfe by these Arguments. If the Spermatieall parts were made of the Seed as of a materiall Principle; then the actiue and the passiue, the Act and the Power; the Mouer and that which is moued; the Matter and the Forme; the Maker and the thing made should be the same; which true and solid Philosophy will not admit. Again, according to Aristotle in the second Booke of his *Physicks*, the Artizan is neuer a part of his owne Workmanship; the Seed is the Artizan. Galen calleth it

Phidias,

Phidias, who was an excellent Statuarie, and made among other Peecces *Minervas* Statue of Iuory 26 Cubits high, &c. And in the 20 Chapter of the first Booke *De Generatione Animalium*: *The Seed is no part of the Infant that is made*, saith the Philosopher; no more then the Carpenter is a part of the Wood which he heweth: neither is there any part of the Art of the Artificer in that which is effected; but onely by his labor through motion, there ariseth in the matter a forme and a shape. Moreouer, it is an Axiome of Physicke, *That we are nourished by those things whereof we are formed, framed and doe consist*; but all the parts of Man are nourished with Blood, & therefore they are all generated of Blood also.

Phidias the Statuarie.

An Axiome in Physicke. The third.

The fourth.

Hippocrates

The fifth.

The sixth.

Furthermore, if the Principall parts, the Heart and the Liuer be made of Blood (for their substance is fleshy, and *Hippocrates* calleth them both fleshy Entrals) why is it not so with the other parts which all Men admit and consent to be made and perfected after them? Adde hereto, that if the Seed of the Male be both the efficient, and the matter of the Infant, there is no reason but the Male may alone beget an Infant in himselfe: Shall the Nature of the Seed be idle and at rest, which all Philosophers with one consent doe agree, is alwayes active and operative? Finally, is it possible that so small a moment of Seed, as ordinarily sufficeth for the Generation of Man, should be sufficient for the delineation of so many hundreds, nay thousands of Bones, Gristles, Ligaments, Arteries, Nerves, Veines, Membranes, &c? Wherefore the Seed hath not the nature of a materiall, but onely of an efficient cause of Mans Generation.

There are also two places in *Galen*, which seeme to fauor the opinion of the *Peripateticks*. The first, is in the second Booke *De Naturalibus Facultatibus*, where he saith, *The Seed is an Effective Principle of the Creature, for the Materiall is the Menstruall Blood*. The other in the third Chapter of the same Booke, where he speaketh verie plainly, *There is great difference (saith he) betweene the workmanship of Phidias and of Nature. For Phidias of waxe can neuer make Iuory and Gold, but Nature keepeth not the old forme of any matter generating of Blood bloodlesse parts. As for example, Bones, Gristles, Nerves, Veines, Arteries, all bloodlesse, yet made of Blood*.

The contrarie opinion of the Physicians Authorities of Galen.

But the truth is, that *Galen* was of another mind, to wit, that all the Spermaticall parts were made of Seed, as appeareth in his Bookes *De Semine*, where he inueyeth purposely against *Aristotle* concerning this matter, teaching that the Seed is both the Efficient & the Materiall cause of their Generation. The Efficient, in respect of the Spirits; the Matter in respect of the Crassament of it. And indeed, that admirable and vnimitable Ingeny or Discourse of *Hippocrates*, did first bring this Light into the World, as appeareth in his Bookes *De Natura Pueri*, *De Principijs* and the fourth *De Morbis*. And *Aristotle* himselfe is constrained to confesse as much in the first Booke of his Physickes, and in his Bookes *De Generatione Animalium*, where he saith, *That some parts are made onely of an Alimentarie excrement, some of an Alimentarie & a Seminall together*. Besides, not to stand vpon authorities, we haue weight of Reason to proue it. The Seed of Man, is white, froathy and thicke, and when it is cast into the Wombe, if Conception follow, it is retained; for out of hand the mouth of the Wombe is so exquisitely closed, that a Needle cannot find entrance without offence.

Aristotle.

Reasons. The first

This all Women know full well; and the Muscull Housewife in *Hippocrates*, when she knew that the Seed she had receiued came not away, on the seuenth day with a *Laualto* I throw, or some such violent friske, she auoyded her Conception. For, if the substance of Seed be retained in the Wombe, it must of necessitie be resolued into nothing, or something must be made of it; or else (as the *Peripateticks* dreame) it must be dissolued into wind and vapors. The first, no Philosopher will assent vnto; for, as nothing is made of nothing, so that which is something cannot vanish into nothing. The last, *Galen* disproueth by this argument, Because when the Seed is conceiued, the Wombe is contracted, & the Seed narrowly embraced on euerie side, so that there is no place left for any distending wind: Adde hereto, that if the Seed were dissolued into wind, the Wombe being distended, whould be afflicted with exquisite torments; for of one part of Earth, are made ten of Water, and of one of Water ten of Aire.

Hippocrates Psaltria. l. b. de nat. pueri.

It remaineth therefore, that of the Crassament of the Seed, some part must necessarily be framed, and those are they which are called Spermaticall, Bones, Gristles, Nerves, Veines, Arteries, Membranes, &c. And this is prooued by their whitenesse, and by the thicknesse, and the lentor or sliminesse of their substance.

Moreouer that the Spermaticall parts are made of Seed, we may thus demonstrate: Bones, Cartilages or Gristles, Membranes and Ligaments, are bloodlesse and white, and therefore

The second.

therefore they cannot be made of Blood immediately, as Flesh; but of Blood changed, whitened & incrassated, and then what differeth it from Seed? Nature therefore should be verie idle, if she should euacuate and expell a matter fit for the generation of those parts, and (as if she had forgot her selfe) should endeavour to bring Blood into that forme of which she had at the first hand Seed enough.

The third.

To these demonstrations of *Galen* (at which *Argenterius* like a Detractor scoffeth) we will adde other Reasons. When the Seed is injected into the bosome of the Wombe, the Wombe is instantly contracted, and the Plasticall or Forming facultie thereof, rayseth vp the sleeping power of the Seed; and then his Spirits and natieue heat, commence their action. Now this action thus instantly begun, worketh vpon some-what: not vpon Blood, because yet there is no confluence of it to the part. For who will say, That in Coition there is a double Secretion, one of Seed, another of Blood at one & the same time? The *Peripateticke* himselfe will not yeeld to such a Solecisme in Nature; but we know, that that which is auoided in the act of Generation, is Seed and not Blood.

The fourth.

It is therefore the Crassament of the Seed vpon which the Spirits do worke, in which they haue their aboad, as in their proportionable subiect; this they turne and tosse on euerie side; the Dissimilar parts of it they separate, framing of the thicker Bones and Gristles, of the slimie Membranes and Vessels; all which, being scored out as the rude and first draught of a Picture, wherein are nothing but the Master-lines; the seuenth day the Blood floweth vnto it, to make the *Parenchymata* or Flesh of the Entrals, and to fill vp the vacant distances of the Fibres. If therefore in the verie conception, no Blood do flow from the Veines of the Wombe vnto the Masse of the Seed conceiued, how can we imagine, that the first delineation of the parts, is made of Blood? Againe, the Blood, where-with the Infant is nourished, and of which the *Parenchymata* are made, must passe by Veines, Veines I say, not of the Mother, for then it would encompassse the Seed onely, not insinuate it selfe into the parts of it; but of the Infant; and for this purpose is the Vmbilicall veine formed, called therefore the *Nurse* or *Foster Veine*, so that this Veine must of necessitie be made before the Blood can come vnto the Seed; and of Blood it is not made, because there is yet no affluence of it. If you shall say, that Blood is poured into the capacitie of the Wombe by the small Veines of the Wombe: I aske, why is the Infant not immediately nourished by the same Veines? what need was there that any Vmbilicall veine should be formed? Finally, another demonstration that the parts are made of Seed, may be on this manner. The Seed of the Male and Female is of one nature, colour and manner of generation, they haue both the same vessels of preparation, concoction and eiaculation, onely they are distinguished in perfection, for that the Seed of the Male is hotter and better laboured. Now all Men doe acknowledge, that the Seed of the Female is the materiall principle of the parts; why then doe they deny it to the Crassament or substance of the Seed of the Male? We therefore conclude and determine, that both Seeds are not onely efficient but materiall Principles of the Spermatieall parts.

The fifth.

The determination.

Answer to the aduerse argument. *Galen* is expounded.

Answer to the first argument.

Auerrohoes

But that we may leaue no enemies at our Backes to interrupt our victorie, as we gaine the Field before vs, let vs make answer to such arguments as are brought against the truth of this assertion. And first for *Galen*: where he writeth, that the Spermatieall parts are made of Blood, he doth not vnderstand an immediate Generation, that is, that the Bones are made immediately of red Blood, as is the Flesh; but of Blood passed through diuers alterations and mutations of Dealbation and Incrassation. And what I pray you is this, but to say they are made of Seed?

To the first argument I answer thus. There are two things to be considered in the Seed, the Spirit and the Body. In respect of the Spirit, *Aristotle* in his first Booke *De Partibus Animalium* saith, the Seed is the nature, the principle and the efficient of the thing begotten; and *Galen* in his second Booke *De Semine*, calleth it, *Formator Fetus*, the Former of the Infant. In respect of the Crassament or Body, it is called a materiall and passiue Principle, so that the same part of the Seed shall not be the actiue and passiue Principle, the act and the power, the moouer and the mooued, the matter and the forme, as the *Peripateticks* would perswade vs it must be, if that opinion were true. And *Auerrohoes* giueth an instance how these respects may be separated, so that the same thing may become the moouer and the mooued in diuers considerations. For example: In a Stone, the grauitie or weight mooueth downe-ward, and the Stone is mooued; so in the Seed, the Spirit is the moouer, and that which is mooued is the Crassament or Substance.

In

In those things that are done by Art, we confesse the Artizane is no part of his owne Workmanship; but in naturall things there is not the like reason. And this *Aristotle* teacheth in the fifth Chapter of his Booke *De Spirations*. There is a difference (saith he) betwixt Art and Nature, for Art vseth heat onely as an Instrument; but Nature vseth it both as an Instrument and as a Matter. For the Fire which is vsed by the Artist to his Worke, is not a part of the Worke it selfe; but the heat, which is in Nature, is diffused thorough the substance of that she intendeth to accomplish. Some learned Men make a two-fold kind of Instrument, *wherewith* and *wherein*. The Instrument *wherewith*, remaineth not in the part which is formed: but that *wherein* remaineth, as being the subiect of the Forming facultie, otherwise there should be a formall transiſion, or transiſion of the forme, out of one subiect into another. For the Forming facultie should leaue his proper subiect, that is, the Seed, and transport it selfe into the Blood.

Answer to the second, *Aristotle.*

To the third; We doe not deny that Bones and Spermatieall parts are nourished by Blood, but that Blood hath gotten and acquired vnto it selfe the nature of Seed, in thicknesse, sliminesse and whitenesse. Or say thus. The Blood is the remote Aliment of the Spermatieall parts, and the Seed or some thing like Seed the immediate.

Answer to the third

To the fourth, The *parenchymata* or Flesh of the Principall parts, are indeed generated of Blood; but their first foundations had their originall from Seed. The Warpe is Seed, the Woofe is Blood.

Answer to the fourth

To the fifth, The Male alone cannot generate in himselfe, although he haue both Principles in him, Efficient and Materiall, because he hath no fit place for conception, nourishment and preseruatiſon of the Infant, yet therefore his Seed cannot well be said to be idle; for that is idle, which when it may or can, yet doth not worke; but in the Male it neither may nor can, because he hath not a Field to sow his Seed in; and the Seed that lyeth in the Garner, cannot be said to be doted, because it groweth not; but if it be put into the Ground, then we know it is doted if it doe not sprout.

To the fifth.

The last reason *Argenterius* makes great account of, for he taketh it to be beyond credance, that all the Spermatieall parts should be made of so small a quantitie of Seed; and therefore that he might be absurd alone, against all consent of Antiquitie, he saith, that no parts are made of Seed. But truth is, that in this there is nothing admirable, but as all the workes of God are iustly to be admired. Shall we see a Spider weaue out of her Wombe a Web a hundred times as long as her selfe, her selfe not at all lessened, and shall we thinke that Nature cannot draw as fine a Thred, and after by addition of competent matter, enlarge the dimensions thereof? But let vs returne to *Argenterius*, and see how Clerke-like he disputeth against *Galen* in this point. It is not possible (saith he) that so many Bones, Gristles, Membranes, Vessels, &c. should be all formed of so little Seed, and therefore none of them are made of Seed. A light and vaine Argument, drawne from the weaknesse of his owne vnderstanding. Doth he imagine, thinke we, that the Geniture conceived and delineated the seventh day, is by that time growne into farther dimensions then the Seed which issued from both the Parents was of? Out of doubt he was not diligent in viewing Abortments. For we dare confidently and religiously auouch, that the first moneth the *Embryo* although articulated, is no bigger then halfe the Thumbe, yea we haue seene it at eleuen weeks old not aboue an inch and a halfe long, and of the thicknesse of a good quill, though all the parts (euen of Generation) were manifestly to be seene and distinguished. If any Man shall call the credit of our asseueration into question, let him heare *Aristotle*, *Probl. 36. Sect. 1. & 7. De Historia Animalium*, where he auoucheth, *if a Male Infant of fourtie dayes growih, be put into any other thing, it will fall asunder: but if it be cast into cold water, it gathereth together, and abideth compassed as it were with a Membrane, which being broken, the Infant appeareth in the magnitude of a great Ant or Pismire, and the Members of his Body may be discerned.* What will *Argenterius* say to this? Is not the Seed of greater quantitie then a great Pismire? Let him remember *Aristotles* Philosophy, That in Principles there is great perfection, little quantitie but abundant vertue. A small Acorne into how vast an Oake will it grow? The nourishment onely is from the Earth: The extent of the parts from the vertue of the Seed. But if he will not belieue *Aristotle*, as scarcely authentick in Anatomy, we will cite him before the Tribunall of Truth it selfe, that is, of *Hippocrates*, who in his Booke *De Principijs*, affirmeth the verie same. *The Geniture in seven dayes hath whatsoever it ought to haue. For common and prostituted Strumpets, when they find they haue conceived, they vndoe it within their owne Bodies by wicked meanes, and*

To the last, *Argenterius*

An example of the Spider.

Argenterius confuted.

The small quantitie of the Infant after it is formed.

Aristotle.

Axiome. Example.

so there falleth from them as it were a flesh: Which flesh if it be cast into cold water, and diligently obserued, you shall in it perceiue all the Members, the place of the eyes, eares, hands, fingers, thighs, feet, toes, and the secret parts. If therefore in the first seuen dayes, the Infant be so small, why seemeth this vnreasonable, that of the Seed at once cast into the Wombe, the first threds and foundations of the Spermatieall parts should be formed, which afterward by the continuall apposition and assimilation of Aliment, receiue their increment and perfection?

The conclusion of the Question.

We conclude therefore, that all the Spermatieall parts are generated of the Crassament or Body of the Seed, or of a materiall Principle. And this Crassament, although it seeme at the first view homogeniall, that is, hauing all parts of it alike, yet notwithstanding containeth in it parts of vnlike natures; thinner, thicker, fatter, flimier, some fit for concretion or gathering together; others for tension and diffusion, all which are separated by the Spirits and heat of the same Seed, stirred vp by the Plasticall or Formative power of the Wombe. And so much concerning the first Question.

QUEST. VIII.

Whether the Spermatieall parts can conioyne againe after they be violated and seuered.

Proofof that the Spermatieall parts may revnite.

The first Argument.

Hippocrates, Galen, Aristotle.

The second Argument.

The third Argument. Hippocrates

The fourth. The fifth. Galen.

The contrarie opinion Authorities for it. Hippocrates

Concerning the Coalition or reioyning of Spermatieall parts, there is great contention; I know that many, as well of the ancient as latter Writers, haue and do maintaine; that they may all reioyne *κατὰ πρῶτον σκοπόν*, that is, according to the first intention, as Chirurgians vse to speake, and this they establish by these arguments. Where the Efficient, Materiall and Finall causes of Coalition are, there is nothing to hinder a Reiunction; but in young, growne and aged Men, this three-fold cause is present, therefore in all such there may be Coalition: The *Maior* Proposition of it selfe is cleere enough; the *Minor* is thus confirmed. The Efficient cause of Coalition is the Forming facultie, which vseth heat as her Instrument; this Facultie is seated naturally in euerie part, but more manifestly in the Solid parts then in the Flethy. The Matter of the Spermatieall parts is Seed, of which there is sufficient plentie, as for nutrition and accretion or growth, so also for a new generation. Hippocrates also, Galen and Aristotle doe agree, that the Seed is an Excrement, or rather Surplusage of the last concoction; now the last and most absolute Aliment is plentiful enough, neuer fayling vnlesse it be in the vtmost limit of decrepit age, and therefore the Excrement or Surplusage of it is not wanting. Moreover, according to Hippocrates, Veines, Arteries, Nerue and all Spermatieall parts haue the power of procreating Seed. Neither is the Finall cause wanting, for a broken Bone and a diuided Veine, do after a sort desire and strue to be revnited; because the solace & comfort of Nature consisteth in vnion, as her sorrow and desolation in solution. They haue also another argument not inelegant; Hollow vlcers are filled vp with new Flesh, intertexted and wouen with small and capillarie Veines, Arterie and Sinews; for that Flesh is sensible, it liueth and is nourished, therefore of necessitie by Veines, Arteries and Sinews.

Who is so mad that he dare exclude the Teeth out of the number of Spermatieall parts? But they grow againe after they be extracted. Hippocrates in his Booke *De Carnibus*, maketh a three-fold generation of the Teeth. The first from the Seed in the Wombe; the second from Milke; the third from more solid Aliments. Now if by the transmutation of the Aliment the Spermatieall parts doe encrease, why shall they not be revnited, seeing that Accretion is one of the kinds of Generation? Galen in the seuenth Chapter of the fifth Booke of his Method, and in the fourteenth of his Method, writeth, *That he hath seene many souldred and revnited Arteries*. He telleth a Storie of a young Man who had an Arterie diuided in his Arme, which afterward did perfectly revnite againe. Also in the 91 Chapter of his Booke *De Arte Parua*, and in the fifth Chapter of the sixth Booke of his Method, he affirmeth, *That the Bones of Children may revnite*. These are the Reasons which they vrge, and wherewith they goad vs to subscribe, That Spermatieall parts, euen according to the *First intention*, may revnite themselues.

Those which haue giuen vp their names against this opinion, doe labour to prooue the contrarie by authorities and by reasons. And first they oppose the 60 Aphorisme of the sixth Section of Hippocrates; *If a Bone, a Gristle, a Nerue, or the Fore-skin be cut, they neuer revnite againe*. Galen in the eighth and tenth Chapters of his first Booke *De Semine*, and also

in

in the 87 Chapter *De Arte Parua*, writeth, *That the Fleſhy parts doe eaſily conglutinate, Spermatieall neuer.* And in the 91 Chapter *De Artis Parua*, He eſteemeth a *Structure in a Bone to be incurable, becauſe Bones doe not reunit according to the firſt intention.* Theſe authorities are ſeconded by reaſons: Firſt, both the Efficient and Materiall cauſes of reunit are wanting. The Efficient is the Formative facultie, which is only in the Seed, whoſe drowſie and luſking Facultie is only brought into act by the heat of the Wombe. True it is, that there remaineth in the Solid parts, a Facultie conſeruing the Figure of the Part; but to make any thing anew is proper onely to the Seed, the Efficient is wanting.

Neither is there any Matter at hand, I meane the Seed; which being generated onely in the Teſticles, how can it be transferred to the Head, the Arme, or any other Part?

Out of theſe waues and ſtormes of opinions, that we may redeeme and eſtabliſh their minds that are yet incertainly toſſed to and fro, and ſet them ſafe on Land in a quiet Harbour, we will determine the whole Queſtion by three concluſions, and theſe concluſions ſhall haue three foundations. The firſt is taken out of the determinations of *Galen*, in the 90 and 91 Chapters *De Arte Parua*, and is on this manner. There is a double reunit of diſſolued parts; *One after the firſt ſcope, another after the ſecond ſcope or intention.* The firſt intention is *ἐν τῇ ἀλλοτρίᾳ*, that is, in *Agglutination*, which we call *ἀσύνθετος*. The ſecond *ἐν τῇ ὁμοίᾳ*, that is, in *Colligation*, which we call *σύνθετος*. The firſt is ſometimes accompliſhed without any medium, that is, without ought comming betweene; as in Fleſh which being cut or diuided, is preſently glued together; ſometime with a medium of the ſame kind, which we call *medium homogeneum*. The ſecond intention is accompliſhed with a medium of an other kind, which we call *medium heterogeneum*, as with a *Callus*, *Cicatrice* or *Scarre*, & ſuch like which are not of the ſame kind with the part diſſected or ſeparated. Now that parts may reioyne according to the *Firſt intention*, and by a *homogenic medium* or meane, many things are required. Firſt, the ſtrength of the Efficient, to wit, of the Formative facultie and of the native heat. Againe, a due diſpoſition of the Matter, which muſt be plentifull, that it may ſuffice Nutrition, Accretion and a new Generation. Moreouer, it muſt be miſtred not by little and little, but together-ward, that is, it muſt be ſuddainly and an once altered, that nothing of a diuers kind may interpoſe it ſelfe betweene the diſioyned parts in the time of that alteration.

Another foundation is this, Of Spermatieall parts ſome are ſoft, as Veines; ſome harder, as Arteries and Nerues; ſome hardeſt of all, as Bones.

The third foundation, That in Infancie and Childhood all the Spermatieall parts are exceeding ſoft, and the Bones like curdled or gathered Butter, and coagulated or ſammed Cheeſe; but in thoſe that are growne to further yeeres, they become dryer, and in old Men very dry, becauſe our life is nothing elſe but a drying of the Spermatieall parts.

Theſe foundations being thus layd, we conclude thus triple-wiſe. Firſt, that Fleſhy parts are eaſily regenerated, and doe reunit according to the *Firſt intention*; but Spermatieall parts very hardly. Secondly, in Children and moyſt natures, all the Spermatieall parts, euen the Bones may reunit by a *homogenic meane*; in thoſe that are growne, ſome parts may, but not all; Veines often, Arteries more rarely, Bones neuer. In old Men there is no hope of coalition in a Nerue, Membrane, Arterie, Veine or Skin, which is called *ῥέπρωσις*; none in a Griſtle broken, eaten aſunder, torne or diſſected, which is called *χρόνις παλαιότης*; none in a Bone broken, which is called *ὀστέωσις*. Thirdly, in all ages and ſexes, euen to the vtmoſt extent of old age, all the Spermatieall parts will reunit according to the *Second intention*, that is, by a medium or meane *heterogenic*, or of a diuers kind, which in a Bone is called *Callus*, in the reſt a *Cicatrice* or a *Scarre*.

The truth of the firſt concluſion is thus confirmed: the mutation or change of Blood into Fleſh, is eaſie and expediate, becauſe it is accompliſhed by a light and almoſt ſingle and ſimple alteration. For Blood is red, hot and moyſt; ſo alſo is Fleſh red, hot & moyſt; one thing onely is required; that the Blood be increaſſated; there is therefore a fit and apt diſpoſition of the Matter. The Efficient is likewiſe verie ſtrong, becauſe Fleſhy parts are hotter then Spermatieall: Whereupon it commeth to paſſe that they ſuddainly reunit, ſometimes without any meane at all; ſometimes with a meane, but alwayes of the ſame kind and *homogenic*; yea oftentimes the Fleſh groweth ſo importunately in wounds (which we call *Hypofarchoſis*) that we are conſtrayned to inhibite and reſtraine the increaſe with *corraſſe* Liniments and Poulders. But on the other ſide, the Spermatieall parts doe verie hardly reunit according to the *Firſt intention*, becauſe of the *weakneſſe of the Efficient*, the

The confirmation of the firſt concluſion.

A three-fold cauſe why Spermatieall parts doe not reunit.

ineptitude

I
The weaknes
of the efficient

ineptitude or vnfitnessse of the Matter, and the siccitie or drynesse of the parts. The Efficient is heat, which being weake, hath enough to doe to intend conseruation and nutrition, and therefore cannot perfectly restore the decayed and vanished substance of the Solid parts.

2
The indispo-
sition of the
Matter.

It is enough (saith *Galen* in the 59 Chapter *Artis Parua*) *if it hinder them from being ex-iccated or dried up.* How shall it then laudably indeauour a new generation, when it cannot preferue them in that state in which Nature produced or brought them forth? Haply there will be a sufficiencie of Matter, but it cannot flow together-ward and at once, because the mutation or change of Blood into Bone, cannot be accomplished but by long interpolation, and many meane alterations: First into Marrow, then into Glew, and so into Seed; of red it must become white; of moyst it must become dry; of liquid it must be incrassated or thickned; in a word, it must alter the temper and all the qualities. Wherefore because the Aliment doth not flow but by little and little to the nourishment of the Bones and the Spermaticall parts; it commeth to passe, that the Excrement which resulteth or ariseth out of the nourishment, doth interpose it selfe between the disioyned parts before the Blood can passe through those diuers alterations, and so breedeth a *Callus*. There is also another impediment from the neighboring parts; as if they be Flethy, they preuent the coalition by filling vp the vacuitie or empirie space.

3
The hardnesse
and siccitie of
the parts.

The last cause of the difficultie of coalition, is the siccitie and hardnesse of the Spermaticall parts. For those things that are dry are very hardly vnited; and the Philosopher in all mixtions requireth some watery moysture, that by it as by a Glew, all the rest may be vnited.

The confir-
mation of the
second con-
clusion.

The second conclusion is thus strengthened: Children because they are not farre off from the principles of generation, haue the Efficient cause very strong and forcible: they haue abundance of Naturall heat, plentie of Spermaticall matter and that very apt, which is suddainly and easily changed, because of the softnesse and suppleness of the Spermaticall parts. In growne Men the Veines because they are soft, and beside at rest from growing and extension, are easily glued together; but the Arteries very hardly, as well by reason of their continuall motion which hindreth revnition, as also because of the hardnesse of the Coates, for they are (as saith *Herophilus*) five-fold thicker then the Veines. Some haue obserued that many parts, albeit they be lost doe neuerthelesse not revnite, because of the excellencie and necessitie of their action; for that the Creature dyeth before they can be revnited; so the Flesh of the Heart being disseuered is neuer revnited, because the Man dyeth instantly, by reason of the interception of a dutie or function of absolute necessitie for the preservation of life.

The confir-
mation of the
third conclu-
sion.

The third conclusion is so euident of it selfe, that it needeth no probation at all; for at all times Spermaticall parts doe revnite by a *heterogenie* meane. If the Skin be wounded there euermore groweth a *Cicatrice* or Scarre vpon the separation. A broken Bone is alwayes & at all times souldred with a knottie *Callus*; notwithstanding, for further illustration two Problemes or difficulties are to be cleared.

The first
Probleme.

The first, Why if a Bone be caued or hollowed by an Vlcere so as there is any losse of the Bone, the Flesh can neuer be generated ouer it? For *Hippocrates* in the 45 Aphorisme of the sixth Section, saith, *All Vlcers that are Annuall must of necessitie loose some part of the Bone vnder them, and the Scarres or Cicatrices become hollow.* Why doth not the Flesh insinuate it selfe into the hollow place of the perished Bone? Or if there be a *Callus* generated, why is there not also Flesh generated about it? I answer, that Flesh cannot be generated in the cauitie of the Bone, because Flesh is not made but of Flesh, neither a Nerue but of a Nerue; now the Lippes or extreame verges of the cauitie are bonie: What therefore shall they endeauour to generate? Surely either nothing at all, or else a Bone or a *Callus*.

The Answer
to it

If in the place of that which is lost there be no body substituted, then is there no foundation layd whereupon Flesh may arise. The Bone it selfe in dry and hard Bodies cannot be regenerated; therefore Nature not being able to doe that she would, doth that she can, so she maketh a *Callus*. But what is the reason why no Flesh can grow vpon this *Callus*? Because Flesh is a liuing and animated thing, and a *Callus* without life altogether: Now that which is animated, and that which is inanimated, that which liueth, and that which is dead, doe differ in the greatest difference, that is in the *kind* and very forme; wherefore the *Callus* which is without life, cannot be a foundation to build Flesh vpon which hath life. That a *Callus* is without life, may be demonstrated, because it is produced of the Excrement of the Bone and the neighbour parts. If it be obiected, that if it be without life

Obiection.
Solution.

Obiection.

and

and not nourished, it could not endure and grow all the time of a Mans life, which that it doth is more then manifest. The answer is at hand, It encreaseth not by Nutrition, but by apposition of the matter, as the Haires and the Nailes: Againe, it endureth as long as the Bones receiue any nourishment, from which there alwayes redoundeth an Excrement, whereby it is preserued.

Solution.

The second Probleme is, Why if the *Callus* come from the Excrement of the Bone, is it not generated in a sound Bone which also yeeldeth an Excrement? Because, when the Bone is weakened by a wound, the Excrements are more plentifully driuen vnto it from the neighbour parts; euen as all the parts that border vpon a wounded part, doe thrust downe their superfluities vnto it. And thus I thinke I haue touched, I hope cleered, all difficulties which concerne the coalition of the Spermatieall parts; it is therefore now high time to turne our discourse some other way.

The second Probleme. Solution.

But before we leaue the Field, it shall not be amisse to disparkle all the forces of our Aduersaries, that we may be said to haue gained an entire and accomplished victorie. The first Argument of the first opinion is true onely in Children; for in old Men euerie Man will confesse there is both a weaknesse of the Efficient, and a want of the Matter.

Answer to the former Obiections. To the first.

The second is a captious Sophisme, made to intrap the ignorant. For it is not necessarie that wherefoeuer there is Sense, there also should be a Nerue, for then the whole Body should be a Nerue; it is sufficient, if a Nerue be deriued vnto the part, by whose illustration and irradiation, all the particles of that part haue Sense; the same we may say of Veines and Arteries. For Mathematicall or locall contaction is not required to euerie action, but onely Physicall and Naturall.

To the second

For their third Argument, I answer, that there is not the like reason of the Teeth, and of other Bones; for the Teeth after they be drawne doe grow againe, by reason of their End, and by reason of their Matter. By reason of their End, because they are ordained to chew, mitigate and prepare the meat for the Stomacke: And therefore as they encrease euen till the end of our age for our necessitie, because they are continually wasted by attrition or rubbing one against another; so for the same necessitie they are regenerated when they faile. Beside, if you regard the Matter of their generation, there is abundance of it contained in the cavities of both the Iawes; adde hereto, that the Teeth are not incompassed with any other part which should hinder their generation.

To the third

Fourthly, they vrge, that Accretion and Nutrition are kinds of generation; but Bones doe grow and are nourished, why therefore may they not be reuinited? We answer, that this is the order and dispensation of Nature; that first the part be nourished; then, if there be any ouerplus, that the part encrease into all dimensions; and after this expence, if there yet remaine any surplusage of Aliment, that then it may goe to the restoring of the want or defect in the part; but Seed is neuer generated in that quantitie, that it should be sufficient for Nourishment, Accretion, and beside for a new Generation.

To the fourth

In the Wombe indeed the Spermatieall parts are easily generated, because both the Matter is copious, and there is moreouer; *διπλοῦς ἔργος*, a double Workman, one in the Seed, another in the Vessels, or as some thinke, in the substance of the Wombe; but after we are borne, they are hardly generated, because one of the Workmen is absent, which formerly was in the Seed, or assistant vnto it. As for the authorities of *Galen*, they doe not conclude either that all Spermatieall parts doe admit coalition, or some alwayes; and therefore we willingly subscribe vnto them, without any prejudice vnto our cause.

Answer to the authorities of *Galen*.

The Argument of the other Opinion, which denyeth the Formative facultie to the Spermatieall parts, yeelding it only to the Seed, is easily ouerthrowne; because the Seed (according to *Hippocrates*, *Aristotle*, *Galen* and all Physitians) containeth in it the Idea or formes of all the parts, which it receiueth from the Solid or Spermatieall parts. True it is, that in the Bones there is, that I may so say, a power to bonyfie or make Bones, in the Veines to veinesie, so there be an apt disposition of the Matter. But when we say that Bones are nourished, encreased, and doe revnite by Seed, we doe not vnderstand prolificall Seed, such as is apt for Generation; that is onely in and about the Testicles, where it attaineth his forme and perfection, but we vnderstand something like vnto Seed. Finally, the authorities of *Hippocrates* and *Galen*, doe conclude onely, that the harder parts cannot revnite, which thing we haue already demonstrated in the second Conclusion. And thus much of the second Question.

Answer to the arguments of the second opinion.

To the authorities of *Hippocrates* and *Galen*.

QUEST. IX.

Whether the Spermaticall parts be hotter then the Flefhy.

I were either superstition or ostentation to quote all the places of *Hippocrates*, *Aristotle* and *Galen*, wherein they anouch, that vnbloody parts are colder then bloody; but no Man that I haue read, did euer deny that Flefhy parts are bloody, and Spermaticall either without Blood, or at least but lightly moystened therewith. Vpon these premises any Man may gather the conclusion; or if they will not inferre it, it will arise of it selfe. Yet there are some among the late Writers, who would faine perswade themselues, that the Spermaticall parts are hotter then the Sanguine or Bloody. *Iobertus* sometimes the learned Chancellor of the Vniuersitie of *Mompelier* in *France*, set forth a Paradoxe concerning this matter, wherein he disputeth many things with great wit and subtiltie; some probabilitie, but lesse substance of truth, concerning the in-bred heat of the Spermaticall parts. I haue alwayes much esteemed the learning and edge of the Mans wit, yet because he is the Chiefetaine of them who haue impeached the authoritie of the receiued opinion concerning this matter; I am constrained to dissent from him, and will not thinke it presumption to examine his Arguments one by one, that the truth may more evidently appeare.

Iobertus
opinion of the
heat of Spermaticall parts.

His first
Argument:

Iobertus

The answer to
the former
argument.
Two things
to be considered
in Seed,
the body and
the spirits.

Those things (saith he) that arise of others doe sauour of the principles from whence they arise; but the Seed from which the Spermaticall parts doe proceed, is hotter then Blood; and therefore the Spermaticall parts are hotter then the Sanguine or bloody. Now that the Seed is hotter then the Blood, may thus be demonstrated. *Hippocrates* calleth Seed fierie and ayrie; Blood cold and waterish. Beside, Blood is contained in a Trough or channell, but the Seed passeth through vessels which haue no sensible cauities, which are certaine signes of the tenuitie and heat thereof. But this reason seemeth to be more washy and loose, then may answer the strength and vigor of so great a Clerkes wit. For there are two things to be considered in Seed (as saith *Galen* in many places) the craftsmanship, corpulencie as I may say, or body of it, and the spirits wherewith it is abundantly stored: In reference to the former the Seed is said to be watery & earthy; in reference to the Spirits, fierie. The Spirits are the Instruments of the Soule, by which that noble Architect formeth her Mansion or Habitation out of the Seed, working and forming it into parts conuenient. These are called forming Spirits, and in respect of these, the Seed is said to be *Artifex*, a Workeman, and carrieth the nature of an Efficient cause. The waterish and cold body of the Seed, is the matter of the Spermaticall parts. I conclude therefore, that the whole Seed considered with all his parts, is hotter then the Blood, because it is fuller of Spirits; but if the Seed be robbed of his Spirits, then is it colder then the Blood; and therefore being auoyded, the heat of it presently vanisheth, and by the coldnesse of the Ayre it becommeth liquid and blackish: and such did *Galen* acknowledge the matter of the Spermaticall parts to be.

Iobertus
his second
argument.

Answered

Iobertus
his third
argument.

This first Argument *Iobertus* strengtheneth with another, thus. The Conformation or Structure, and Scite or Position of the Spermaticall parts doe manifestly proue their heat: For the Bones occupie the in-most place, and are couered on euerie side with Flefhy, as are also the Nerves, least their ingenit or in-bred heat should vanish or be offended by the coldnesse of the ambient Ayre; but the Flefhy is placed about the vtmost parts. By which Argument I cannot see what he would conclude, for these things doe rather argue the coldnesse, then the heat of the Spermaticall parts; for because cold was their greatest enemy, that their weake and languishing heat might not be extinguished, Nature did on euerie side cherish them with Flefhy, and inuest them with Membranes for their defence. Moreover, the Bones are not seated so farre within for the preservation of their heat, but because they should serue as a stay and prop to vphold all the rest of the Frame. But if he will conclude, that the externall parts are colder then the internall, it will follow that the Skin (which all Men acknowledge to be temperate) is colder then either Nerves or Bones.

His third Argument is yet more liable to exception. The Spermaticall parts (saith he) are easily offended with the cold, therefore they are hot, for alteration is made by contraries, conseruation by things that are alike. But this is vtterly opposite to *Galen*s Philosophy,

phy, who in his Booke *De Arte Parua*, giueth this as a generall rule, whereby we may distinguish the temper of the Parts: That those which are easily offended with cold, are cold, and the hot with heat. So saith *Hippocrates*, cold is the greatest enemy to the Bones, Nerues, Teeth and Marrow of the Backe, because these parts are cold. *Galen* hath these expresse words in the 59 Chapter of his Booke *De Arte Parua*, *In all parts this is a common marke of the temperature, if the Member doe easily grow cold, it is a signe of frigiditie or raritie; if hardly, of heat or densitie; if drying things offend it, then it is dry and rasby; if moist things, then it is moist.*

Answered
Galen.

Hippocrates

Finally, *Iobertus* addeth this last Argument. That many actions of the Spermaticall parts doe testifie that there is in them a vehement and high degree of heat; so the Stomacke which is Membranous, attenuateth and boyleth the Meat though it be verie hard; yea, the Estrich softneth Iron in her Maw. The Bladder which is likewise Membranous, baketh the Stone harder then the Kidneys, which are fleshy parts. These obiections may at first sight seeme of some moment to those that are not sufficiently grounded in our Art, but we will labour to shew their weakenesse and insufficiencie. First therefore, that obiection concerning the Stomacke is full of error: For those Creatures in whom the innermost coat or membrane of the Stomacke is more fleshy, doe boyle their meat more strongly: And those Creatures which haue no Teeth, as Birds, haue a solid Flesh, and verie full of warmth annexed to their Corps; and as for Men, the inward coat of their Stomackes is lined ouer with a fleshy crust, which *Fallopins* first of all Men obserued. But goe too, let vs yeeld this vnto him, that the membranous Stomacke doth more perfectly boyle, the membranous Bladder bakes the Stone harder, yet it will not thereupon follow that the Spermaticall parts are the hotter, but that the heat when it is retained in a more solid and fast matter, burneth more powerfully. Who will say that a glowing Iron is hotter then a flame of Fire? No, it burneth more fiercely, but yet the degree of his heat is more remisse. So Fire in his owne Spheare, and in *Aqua-vite* doe not burne, because of the tenuitie and thinnesse of the matter. For the Stone, it is not generated so much by a sharpe and biting heat, as by long continuance in the part, and of the visciditie and sliminesse of the matter, as we see in old Men. Hence therefore it appeareth that the Spermaticall parts are not hotter then the Fleshy. Neither must we admit the distinction of *ingenit* and *influent* heat; because if there be a collation or comparison made, it must be betweene equals. And thus much of the third Question.

Iobertus
fourth
Argument:

Answered.

A good obseruation of
Fallopins.

Comparison

Aqua-Vita.

QUEST. X.

Whether the Solid parts being once dried, can be made moist againe.

Here is also beside the former three, another By-question, concerning the moistning of Solid parts after they be dried: For the opening whereof, we must vnderstand, that the name of a Solid part is verie ambiguous and equiuocall. The common people call that a Solid part which is firme, hard, dense or thight, and well compacted or knit together. So *Galen* calleth the Flesh of the Heart, Solid Flesh. *Hippocrates* in the seuenth Section of his sixth Booke *Epidemion*, calleth all the containing parts Solid, and thus Fleshy parts also shall be esteemed Solid. Some there are who by Solid, vnderstand all Animated parts, which haue a proper circumscription, and are bounded within their owne limits. Philosophers call that Solid, which is *ᾠλον, tale*, that is, wholly full of it selfe: So the Fire and the Ayre in their owne Spheares are said to be Solid. So *Cicero* in the first Booke of his *Diuinations* saith, That when *Alexander* determined to weare a Crowne of Gold, he made doubt whether it should be of Solid Gold, or onely laid ouer with Gold on the out-side: And according to this acception, all the Similar particles (as we haue already shewed) are called Solid, because all parts of them are equall and alike. But most properly the Physitians call those Solid parts, which are Spermaticall, as *Galen* teacheth in the first Chapter of the eleuenth Booke of his Method, and in the seuenth Chapter of his first Booke *De Naturalibus Facultatibus*, as also in the sixteenth Chapter of his first Booke *De Semine*, in all which places hee calleth Fleshy parts, Bloody, and Spermaticall parts, Solid. These Solid parts in the nine and fiftieth Chapter of his Booke *De Arte Parua*, he calleth *Primas* or the *First*; either because they are

the Foundations of the rest, and as it were the first Threds and Lines which support the whole Fabricke of the Body; whereas the Flesh doth but as Rubbish fill vp the emptie spaces betweene them; or else because Seed is the first principle of the Body; or lastly, because the Spermatieall parts are generated before the Flethy. Now the Question is concerning these true and properly so called Solid parts; whether if they be reficcated and dried, they may be by Art or Nature moistned againe; that is to say, whether the Aliment that is substituted be of the same kind with that which is wasted. Galen was the Man who gaue the occasion to this Question in the 59 Chapter *Artis Parua*. *Solid parts* (saith he) *of the Body can by no meanes be made moister, it is all we can doe if we can keepe them from drying.* And in the first Chapter of the eleuenth Booke of his Method. *The quantitie of the Solid parts remaineth alwayes the same.* And in the eleuenth Chapter of the tenth Booke of his Method, *The ficcitie or drynesse of the Solid parts can by no meanes be cured.*

We imagine that this doubt may easily be assoyled, if we remember that in the Solid parts there is a double substance; one exquisitely Solid and Fibrous, altogether without Blood; another which filleth vp the distances of the Fibres, which is called the proper and peculiar *Flesh* of euerie part. The first can by no possible meanes be humected or moistned, that is to say, neither *such* nor *so much* can be restored *how much* and of *what kind* is spent or consumed. The latter may easily be restored. But least you shall thinke this distinction to be a Brat of my owne Braine, you shall heare Galen making mention of the verie same in his Medicinall Art, and in his Booke of Method. In the 59 Chapter *Artis Parua*, *The Solid parts* (saith he) *which are truly Solid and First parts, can by no possible meanes be moistned; it is as much as we can doe if we can hinder them from being ouer-soone exiccated or dried up, but the inter-middle spaces may possibly be filled with this or that moysture.* In the eleuenth Chapter of the tenth Booke of his Method, *In the Solid parts there is a Fibrous substance and there is a Flethy; so a Veine which hath but a thin Coat, hath many Fibres intertexed or wouen with it, to which the proper substance of the Veine groweth. This hath yet gotten no common name; but by way of instruction I see no reason but you may call it the Flethy-substance.* This distinction therefore is Galens owne, and therefore the fitter for vs to rest in. And so we haue gone through all the Controuersies or difficulties that concerne the nature of a Part, which we esteeme to be the proper Subiect of Anatomy. It remaineth now that we addresse our selues forward on our businesse.

(* *)

The end of the Controuersies of the first Booke.

Of the parts Inuesting, and Containing the
whole Body: And also the lower
Belly in particular.

THE SECOND BOOKE.

The Praeface.

Being now to dissolue this goodly frame of Nature, and to take in pieces this Master-piece, it shall not be amisse to take a light survey of all the parts as they lye in order, beginning with that which first meeteth with the sence. This body therefore, which indeed is but the Sepulchre of that which God at first created, although to the eye it is very specious and beautifull, yet is it but infirme and weakly defended, so that the soule is truely said *Inhabitare immunitam Ciuitem*; for to death and diseases wee lye open on euery side. The World is a Sea, the accidents and diuers occurrents in it are Waves, wherein this small Barke is vexed, tossed, and beaten vp and downe, and there is betwixt vs and our dissolution, not an inch boord, but a tender skinne, which the slenderest violence euen the cold aire is able to slice through. How then may some say, commeth it to passe, that so weake a vessell should liue in so tempestuous a Sea, should ride out so many stormes and dangers? Surely, it is put together with wonderfull Art, and framed according to Geometricall proportions, which the English Poet hath obscurely but excellently described vnder the type of the Castle of *Alma*, that is, of the soule.

The Frame thereof seem'd partly Circular,
And partly Triangular: *o worke Diuine!*
Those two, the first and last proportions are;
The one, imperfect, mortall, feminine;
The other, immortal, perfect, Masculine:
And twixt them two, a Quadrate was the Base,
Proportioned equally by seauen and nine;
Nine, was the Circle set in Heauens place,
All which compacted, made a goodly Diapase.

So that trueth to say, it is not the matter, whose commencements are dust, and con-summation clay, but the excellent proportion and structure that maketh this Paper-sconce high perill-prooffe.

We list not againe to retriue the wonders we haue already sprung, least we should seeme to mingle Yarne to lengthen out our Webbe: Our paine is as great in choise, as others is in want. For he that would summe vp all the rarities of Nature, which she hath packed together in that goodly Cabinet, had need of the Sea for his Inke, and the Sand for his Counters. It shall be sufficient in this place, to draw the Curtaine and to shew you
G the

the Case, rather the Coffin or winding-sheet wherein Nature hath wrapped this living Body of Death. Those are foure besides the Haires, wherewith as with Flowers the Coffin is garnished, that is, the Cuticle or Scarfe-skin, the Skin it selfe, the Fat and the fleshy Membrane.

The Haires are a velature or couering for the more vncomely parts, a defence for the Head, which we may encrease or diminish, keepe on or leaue off at our pleasure and for our necessitie, an ornament for the Face, and finally, a conuenient out-let and way of ex-
pence for the thicke and smoakie vapors, which otherwise would smother and choake the Braine.

The Scarfe-skin or Cuticle being void of sense it selfe, is ordained as a muniment to defend the Skin from the violence of outward iniuries; to attemper his exquisite sense, and so become the *medium* or meane of sensation; to cover the Orifices or mouths of the Capillarie and hairie or small Vessels, which determine in the Skin that the Blood issue not from them; to sucke vp the vaporious moisture which otherwise would indecently well out of the Pores of the Skin and insensibly to euaporate the same, which we call Transpiration; and finally, to turne the roughnesse and inequality of the Skin into a soft and slicke smoothnesse, and so becommeth one of the principall beauties of the Body.

The Skin it selfe is the Wall of the Castle, so quaintly framed, that the more fiercely it is besieged by the cold, the more safely it doth defend, and the more strength it doth giue to the inward parts: And therefore *Hippocrates* saith, *In winter the Belly, that is, The inward parts of the Body are hotter*; the reason is, because all the Spirits are immured, and the naturall heat restrained from vaporeing forth. But when the outward enemies are departed, then it openeth it selfe on euerie side, so cleansing the Body of such superfluities, as in the time of constraint were contracted.

Next vnder the Skin lyeth the Fat, a Pillow to the Vessels which run vnder it; a complement to fill vp the vacant distances of the Muscles, thereby making the Body plump, soft and better proportioned; a light and soft vesture to keepe the subiected parts warme in Winter and in Summer to defend them from heat. Finally, a Stowage or Magazine of nourishment against a time of Dearth: For being dissolved by the naturall heat, it melteth into a Blood-like vapor, and returneth againe into the Vessels, and so becommeth a subsidiarie Aliment in times of Necessitie, Nature being at her owne finding, and teaching vs with how little she can content her selfe.

Finally, the fleshy Membrane as an Auant-mure or inward Counter-scarfe, is ordained as a secret defence to hold out a second assault, if the outward should be won by the enemy; it preserveth also the Fat, that it is not molten with the perpetuall motion of the Muscles; it supporteth and sustaineth the passages of the Vessels, which run from within forth to the surface of the Body; and to conclude, as a Mound of Earth within a Citie, serues to make vp the breaches of the Wall, so doth this Membrane being fleshy, helpe to consolidate the Skin being wounded, or otherwise violated, which without Flesh was impossible to be accomplished. And these are the outward defences which are generall to the whole Body. There are some also more particular to the lower Belly, with which in our Anatomieall administration, we must begin according to the order of Dissection: But first we will giue you a generall view of all the regions and outward parts of the Body, calling euerie one by their names, and disciphering them in two Tables, to which we haue added also their exposition, that the young Anatomist being in the beginning acquainted with the appellations of the outward parts, may not be puzzled in the future Discourse.

CHAP. I.

A Division of the body of Man.

Dioles Caristius in an Epistle to King *Antigonus*, diuides the body of Man into the head, the chest, the belly, and the bladder. The Egyptians into the head, the necke, the chest, the hands, and the leges; we will part it into three regions, and the ioynts. The three regions are, the vpper which is the head, the middle which is the chest, and the lower which is the belly. The vpper region or the head, is circumscribed or limited by the crowne, and the first racke bone of the necke. The second Region the later writers doe call *venter medius*, or the middle belly and the chest: *Hippocrates* in his Aphorismes calleth it the vpper belly, but in reference to the lower: and the chest in his Booke *De Arte* is taken for the whole trunke of the body, for he writeth, that the *Liuier* is situated in the Chest. This second or middle Region is likewise limited by his bounds, the vpper part with the *Clauicles*, so called, because they do *claudere*, that is, shut vp the Chest; we call them patelbones: below with the brest blade and midriffe, which like a partition wall distinguisheth this middle from the lower region. On both sides it is enclosed with twelue Ribs, before with the brest bone, be-

Diuers diuisions of the body.

Our diuision. The vpper region which is the head.

The middle region which is the Chest.

TABVLA I. The first Table, shewing the outward and fore-parts of the body.

 From o. to e. the pillar of the necke, *truncus*, and *δελτος*. G. the yard with the foreskinne, *peccus cum praputio*.
 pp The hollow of the necke, called *inguli*, *σφαρδα*. H. the stones or testicles, with the cod or *scrotum*.
 qq. The patell bones, *clauas*, *κλειδες*. II. the shoulders *humeri*, *επιωμιδες*.
 r. The chest *pectus*, *σενον*.
 s. The right brest. KK the arnes *Brachia*, *βραχια*.
 ss. The left brest: to this Region we apply cordiall *Epihemations* L. the bowt of the arme, called *Gibber*, *αγκων*.
 tt. The nipples of the breasts, *Papil*. M. the outside of the lower part of the arme cald *cubitus*, *πυγ*.
 la *θαλα*. N. the wrist cald *Brachiale*.
 u. The trench of the heart which the Ancients called *καρδια*. The O. the after-wrist *postbrachiale*, *μετακαρπιον*.
 The Latines *scrobiculus Cordis*. This part is anointed for the mouth of P. the Palme called *Palma* or *vola manus*, *θεναρ*.
 From u to E. the lower belly, *γαστηρ*. φ the backe of the hand *Dorsum manus*, *δποσθεναρ*.
 x. The *Epigastrium* or vpper part of the lower belly, *γαστηρ*.
 y. The *Epigastrium* or vpper part of the lower belly, *γαστηρ*.
 z. The *Epigastrium* or vpper part of the lower belly, *γαστηρ*.

QQ. the fore and middle part of the thigh, where we apply cupping glasses to bring downe womens courses, *μητρον*. RR. the knee, *genū*, *γονυ*. SS the Leg, *Tibia*, *κνήμιν*. TT. the calfe of the Leg *sura*, *γαστροκνήμιν*. VV. the instep, *tarsus*. XX, the top of the foote *Dorsum pedis*, *σηδ* *ποδός*. YY. the inner Ankles, *σφυρα*. ZZ. the outward ankles, *α* the toes of the feet. β the place vnder the inward ankle, where the veine called *Saphena* is opened.

The Second Table, shewing the outward, and
backe parts of a Man.

A. The forepart of the head, *Sinciput*, βρεγμα.
B. the top or crowne of the head *vertex*, κορυφή.
C. the hinder-part of the head, *occiput*, κολίς
κινιδόν.

From D. to D, the face, *Facies*, πρόσωπον.

E. the eyebrows *supercilia*, ὄφρυς.

F. the vpper eye-lid, βλεφαρον.

* G. the tip of the nose cald *Globulus nasi*.

H. the back part of the neck, cald *carnix*, ἀνχιγν. and
the nuke or nape of the necke, there is a hollow-
nesse at the top of this *carnix*, where we apply Sea-
tons.

I. the backe part of the shoulder top, called *axilla*,
ἄμω.

KK. the shoulder blades *scapulae*, ὠμοπλάται.

1, 2, 3. On this place we set cupping glasses.

4, 5, 6, 7. the backe *dorsum*, ὠστών.

8, 9. the ridge, *spina dors*, ῥάχης.

L. the arme hole, *ala*, μυχάλυ.

* the elbow, *Gibber brachij*.

MM M M. the sides, *Lascera*.

NN. the loynes *Lumbi*, or the region of the kidneys,
ὀσφύες.

OO. the place of the hips, *coxendices*, where wee
apply remedies for the Sciatica.

P. the place of the holy-bone, or *Os sacrum* where we
apply remedies in the diseases of the right gut.

Q. the place of the Rump or *Coccyx*.

RR. the Buttocks *Nates*, κλῶνες.

SS. the backe parts of the thigh, *Femur*,

TT. the ham, *Poples*, ἰχνός.

VV. the Calfe of the Leg, *fura*,

XX. the foote or *parvus pes*, πούς.

YY. the vtter ankle, *Malleolus externus*.

ZZ. the heele, *calx* or *calcaneus*, πτέρνα.

aa. the sole of the foote *Planta pedis*, κόλον τῆς ποδός.

b. the inside of the lower part of the arme called *Vlna*,
ῶλένη.

c. the outside of the same, *Cubitus*, πυχός.

dd the wrest, *Carpus*.

ee. the backpart of the hand, *dorsum manus*. g. the fore-
finger *index*, ἰνδύχων. h. the thumb, *pollex*, ἀνίχης.

i. the middle finger, *medius*, μέστος. k. The ring-finger *Annularis*, μεδικός, ἰνδύχων. l. the little finger, *Auricularis*, ἀνιχίς.

The third re-
gion which is
the belly.

partly fleshy.

Why the low-
er is altoge-
ther fleshy.

behind with the backe; round about, on the outside, with many Muscles, on the inside with
a Membrane which compasseth the ribs. The third Region is called the lower belly, circum-
scribed aboue by the brest blade and the Midriffe: below, by the hip-bones, the Hanch bones
and the share-bones: behind, by five racke bones of the loynes, and the holy or great bone;
and before, by the whole *Abdomen* or paunch. The rest of the body we call the Ioynts, in La-
tine *artus*, and those are the armes and the legs, which like boughes or branches, grow out of
the trunk of the body. In the vpper region, are contained the Animall organs, that is, the
braine, which is the seat of the soule, and the originall or fountaine of sence and motion. In
the middle region, are contained the vital parts, and parts seruing for respiration, as the Heart,
the Luugs; and the arteries. In the lower region are contained all the naturall organs seruing
for concoction of nourishment, expurgation of excrements, and procreation. And therefore
the vpper Region is called Animall, the middle Spirituall, and the lowest Naturall. The vp-
per is walled about on euery side with bones, as it were a strong bulwarke or Peece for de-
fence, because in it, the soule which is the Queene of this Little world, keepeth her residence
or state. The middle is partly bony, and partly fleshy: bony, for the strength of the heart, and
to frame the cavity; and fleshy, for the more facile motion of the Systole and Diastole. The
lower region is before altogether fleshy, that it might better be contracted and distended into
a greater proportion for the concoction of the aliment, reception of the excrements, and for
the containiing and increase of the infant.

In

In which position of parts who can but admire the wonderfull providence of the Creator? The Animall Region he hath set in the highest place, as well for the conueniencie of the senses (for the voice is better heard from aboue; the smell receiueth best an ascending vapour, and the Eyes which are as Scout-watches & Spies, do see furthest from aboue) as also because it was conuenient that the principall faculties of the Soule should be as farre distant as they might from the noysome vapours which doe exhale from the parts where the Aliment is concocted and the Excrements are retained. The Spirituall Region, which is the well-spring of heat and source of life, is placed in the midst, that it might diffuse his sweet influence as well into the lower as into the vpper parts. The Naturall Region, as it were the Kitchin, is built neere the ground, that the Excrements might better settle from the more noble parts, and be also more cleanly conueyed away. And this shall suffice for a brieue diuision of the whole Body, and description of the three Regions, through all which we will walke at more leasure, to obserue the diuers parts therein contained. But our perambulation shall not be in an order answerable to the dignitie of the parts, but rather Anatomicall. For they that dissect dead Bodies, doe first open the lower Region, because it is the Sinke of the Body and will soone be corrupted vnlesse the parts therein contained be taken away. We therefore from it will commence our Discourse.

Why the Animall Region is highest.

Why the Spirituall Region is in the midst

Why the Naturall is placed below.

The order of Dissection.

CHAP. II.

The diuision of the inferiour or lower Belly.

THE inferiour or lower Venter, which we commonly call the Belly, in Greeke *γαστήρ*; is almost the middle part of the Bulke or Trunke of the Body, distinguished from the Chest by the *Diaphragme* or Midriffe; and is circumscribed or bounded aboue by the Breast-blade at the end of the Brest bone, below at the Share-bone, before by that which is properly called the *Abdomen* or Paunch (for some call all the lower Belly by that name, whence those that are great gormandizers are said to be *Nati Abdomini*, that is, born for their Bellies) behind by the Spondels or Rack-bones of the Loynes, and the Sacred or Holy-bone; on both sides by the Ribs, the Bones of the Hips and Haunches. This Venter, because it was to containe the Members of Generation and Nutrition both, hath allotted vnto it the most ample cauitie or hollownesse of the whole Body. It is therefore placed below, that it might better receiue the recrements or excrements of both concoctions, and more easily and cleanly conuey them away. Before and on both sides it is fleshy, that it might be dilated or stretched out, as well for the receiuing of Nourishment, as for the containing the increase of the Wombe, or else be compressed and straightned when need shall be for the exclusion or auoiding of Excrements.

The situation of the lower belly.

Why it is placed below.

Why so fleshy.

It is diuided into two parts, the fore-part and the hinder-part; The fore-part, which *Galen* calleth *ενωδισιον*, and the *Arabians* (though their part of Anatomy we may without great detriment to our Art forget) *Mirach*, *Galen* diuideth into three parts: the *Hypochondria*, the Region of the *Naui*, and the Water-course or *Hypogastrium*: Wherefore in imitation of him we also will diuide it into the Vpper, the Middle and the Lower Regions.

How it is diuided
The fore-part
The vpper part or Region of the *Epigastrium*.

The Vpper, which is limited by the Sword-like-cartilage or the Breast-blade and the ends of the Ribs, hath three parts; two laterall or side-parts, properly called *Hypochondria*, because they are vnder the Cristles of the Bastard-ribs, for so much the Greeke word signifieth. *Celsus* by a like kind of notation calleth them *Pracordia*, because they be vnder the mouth of the Stomack, which the ancient *Greekes* called by the same name with the Heart. In the right *Hypochondrium* is placed the greater part of the Liuer; in the left, the Spleene and the greater part of the Stomacke. The third part of the vpper *Epigastrium*, which also standeth in the Front, hath deseruedly gotten the name of the whole, and is truly called *Epigastrium*, because the Stomacke lyeth vnder it, which by an excellencie is called *Gaster* or the Belly. In this place is that cauitie which the later writers call *Scrobiculum Cordis*, the hole or spoone of the Heart; the ancients called it *Cardia*. The Middle part of the *Epigastrium* is the Region of the *Naui*; it is circumscribed on both sides, with the ends of the Ribs & the right line of the Haunch-bone: it hath likewise three parts; two laterall which *Galen* calleth *κονιδιας*, i. void, because the place is without Bones: and *Aristotle* *καγδιας*, because they are lax and loose; some call them *Ilia*, we call them the Flankes. On the right side is

the Blind gut, and a part of the Collicke gut, and a part of the Emptie gut called *leinum*. The third part of this Middle Region of the *Epigastrium* is the Front, where the Nauill is seated, called *ομφαλος*, or *Umbilicus*; this is the very center of the Body, and vnder it lyeth almost all the Emptie guts.

Vnder this Region of the Nauill, is the Lower Region and third part of the *Epigastrium*, and it reacheth as farre as the Share-bone. It beginneth at the Spine or swelling of the vpper circumference of the Haunch-bone, and if you draw a Line crosse from either side vnto the Middle space betwixt the Nauill and the Spines or Protuberations of the Share-bones, you haue the full extent of this *Water-course*. Of some in a large signification it is called the Little belly, but more strictly they would haue it to be that part onely wherein the Bladder is contained, following as it should seeme *Diocles Caristius*, who diuided the Body into the Head, the Breast, the Belly and the Bladder. This Small belly is distinguished from the Greater by a certaine fence or mound, made of the production of the *Peritoneum* or the Rim: which production stretcheth from the necke of the Bladder to the backe part, and the bottome thereof euen vnto the Nauill, and this production is vp-held and sustained by three Ligaments: two of which are called the *Umbilicall Arteries*, and the third is called *Vrachus*. This Little belly *Hippocrates* calleth *Τριτον*, and *Galen Hypogastrium*, the *Latins Aqualiculus*, because the Excrements haue in it their *Rendezvous* or place of assembly: For in the fore-part it hath the Bladder and the Gut called *Ileon*, in the hinder part the Right gut, and betwixt these in Women is the seat of the Wombe. This Little belly is also sub-diuided into three parts, two laterall and a middle; the laterall reach to the place where the Haire buds, and are called by *Celcus, ilia*; because they containe the Gut called *Ileon*, and the Spermatick vessels; we call them the Flankes. The Middle or fore-part reaching to the very Yard, is properly called *Hypogastrium*; whose right & left parts which in the bending of the Thigh, side or leane to the Share-bone, are called by *Aristotle, Bombones*, (which name those tumors that arise in these parts doe yet retaine) by the *Latines, Inguina*, which is with vs properly called the Leske. The third and fore-part of this *Hypogastrium*, where the Haires grow tufted and ranke, is called by *Hippocrates* and *Aristotle, νῆς*, in *Latine, Pecten* or *Pubes*, with vs the Groyne; yet *Pubes* doth more properly signifie the Down or Cotton when it ariseth about those parts in Men, neere vpon the fourteenth yeere, in Women about the twelfth; and it is a signe of maturitie or ripenesse. For (that I may vse *Hippocrates* words in his Booke *De Natura Pueri*) as soone as the passages are open for the Seed or Monthly courses, the Haire or Downe in a Boy or Girle starteth vp, the Skin being rarefied or made thin. Vnder these are the Priuities, called *Pudenda*; the very name carrying the remembrance of our shame and of our sinne.

The backe part of the inferiour Venter or Lower belly, is limited by the end of the Ribs and the extremitie of the Rump-bone, this part some call *δίζωα*, that is, *Cinctum*, the Girdle-head, giuing the name from the vpper part; or if you will, *Subligaculum*, the Breeches, for the *Greeke* word will beare both, and then it taketh his name from the whole.

It is diuided into an vpper and an vnder part; the vpper is from the bending of the Backe vnto the Buttocks, which makes the Loynes, *Aristotle* calls them *σοφύς*: the fleshy parts on either side are called in *Greeke* *Ψόν*, *Pulpa a palpando*, in imitation whereof, we call it the Filler as it were Feele it. On the right side lyes the right Kidney, and on the left side the left. Below the Loynes are fleshy and globous or round parts diuided by a Fissure called by *Herophilus* *Σιχάλα*, by vs the Cleft. *Aristotle* calleth them *ῥοχία*, because they sustaine a Man when he sits, and we call it mannerly the Seat: He calleth them also *γυμνί*, in *Latine Nates*, *ab innitendo*, because they serue in stead of Quishions to sit vpon, we call them the Buttocks. Betwixt these is the *Coccyx* or Rump-bone, and vnder them as in a low valley, lye the verie end of the right Gut and the place of siege, the Port *Esquiline* or the Fundament.

CHAP. III.

Of the composition or frame of the Lower belly.

THE Inferiour or Lower belly consisteth of two sorts of parts; one called Continent or Containing and Inuesting parts, the other parts Contained. The Inuesting or Containing parts which properly make the *Abdomen*, (for they hide and conceale the Bowels or Entrals and the Guts scituated in this Lower belly, called therefore

therefore of the *Greekes* *ἐντὶ τῆς κοιλίας*, that is, about the Belly) are also of two sorts, Common or Proper. The Common, are the Cuticle or the Curtaine or Scarfe-skin, the true Skin, the fat and the fleshy Membrane; for they encompassse all the whole Body, excepting some particular parts, as we shall shew afterward. The Proper inuesting parts, are the Muscles of the Paunch or of *Abdomen*, and the *Peritonem* or the Rim of the Belly; for these are proper to the Lower belly, euerie Venter hauing his proper inuestiture vnder the Common containing parts. And of these we will intreat in order, sauing of the Muscles, which we will referre into their proper place, in the Booke of the Muscles.

The common
Inuesting
parts.
The proper

CHAP. IIII.

Of the Haires of the whole Body.

HE Haires in *Greece* are called *τριχες* *quasi* *θρίχες*, *ὅτι θρίσονται*, because we mow or poule them. *Persius* calls them *Cirri*, from the *Greece* Verbe *κίρειν*, which signifieth to cut. In *Latine* they are called *Pili*. Almost euerie liuing Creature that ingendred within it selfe, is furnished with this couering, some more, some lesse: and yet there are, which in stead of Haires, haue Pricks, as Hedge hogs and Porcupines; others haue Feathers, as Birds (and therefore the fauour of Feathers and Haires when they are burnt are alike) others Scales, as Fishes.

The names of
Haires.
*Arist. 1. Gen.
Animal. 3.*

Haires and
Feather of a
like substance.

Haires are bodies engendred out of a superfluous excrement of the third concoction, torried by the naturall heat; and they grow especially where the Skin is thinnest and most temperate, and where there is for their nourishment some proportionable quantitie of moisture. So that for their generation or production and their conseruation, foure things are required: The Heat for an Efficient cause, the Matter out of which they are generated or produced, a conuenient place for their production, and fit and competent nourishment, or rather apponed matter to be continually ministred for their preseruatiou.

Whereof
Haires are in-
gendered.

Foure things
required to
the producti-
on of Haires.

The Matter of the Haires is either remote, or more immediate: The remote Matter is a superfluous moisture, which the Kernels or *Glandules* which are disposed in the fobby and watrish places of the Body could not sucke vp, which moisture therefore is thrust out into the Skin. Hence it is, that wherefoeuer there are any Kernels, there are also Haires: and verily *Hippocrates* in his Booke *De Glandulis*, assigneth the same profit vnto them both. The *Glandules* to receiue that Matter which applyeth vnto them, the Haires to gather it in o their nourishment or for their production, being expelled by Nature as a superfluitie. So we see there are *Glandules* behind the Eares where also are Haires, vnder the Arme-pits Haires and *Glandules*, in like manner in the Flankes & the Groyne. And if in any part there be *Glandules* and no Haires, *Hippocrates* in the place next about quoted, rendreth the reason, because there is too great plentie of moisture. For we see that in fobby and sunken grounds Seed will not take root, nay the Graffe it selfe will not grow where the Water standeth continually.

The Matter.
Remote.
*Hipp. De Nat.
Pueri.*

In principio,
where are
Glandules
there are
Haires

Exceptions,
& the Reason

The next and immediate matter of Haires according to *Galen* in the fifth Chapter of the second Booke *De Temperament*, is a sootie, thicke and earthy vapour, which in the time of the third concoction, when the Aliment is turned into true nourishment of the parts, is eleuated by the strength of the action of naturall heat, and passeth through the Pores of the Skin. The Efficient cause is as we said, a moderate action of the naturall heat, which exciteth or drieth this moisture or these sootie and thicke vapors, and thrusteth them out by the transpirable passages of the Skin. For the vapour being thicke, in his passage leaueth some part of it selfe, to wit, the grossest in the very out-let, where it is impacted and by a succeeding vapor arising whence the former did, is protruded or thrust forward; and so one vapor continually solliciting & vrging another, they are wrought together into one body: euen as in Chimneys we see by the continuall ascent of Soot, long strings of it are gathered as it were into a chaine. The difference is, that the straightnesse of the passages of the Skin, where through the matter of the Haires is auoided, formeth them into a small roundnesse, euen as a wire receiue that proportion whereof the hole is, where through it is drawne.

The imme-
diate matter.
Galen.

Their
Efficient.

The manner
of their
production.

Comparison

The manner of the out-gate of this matter, is thus. When by the continuall appulsion or arriuall of such vapor to the Skin, the Pores are plenarily obstructed; then the next vapor that striveth to be at libertie, smiteth the former; which by reason of the straitnesse of

A fit Compa-
rison.

of the passage, is driuen out into the forme of a cord. He that would see an expresse Image of this manner of production, let him resort to a Glasier, when he extendeth his Metall into the guttered Lead wherein he fastneth his Glasse, and he shall perceiue how the Artift hath made an Engine, whereby an inch of Lead is driuen out, into a foot almost of length.

Hippocrates. It was necessarie therefore, saith *Hippocrates* in his Booke *De Carnibus*, that this footie excrement should haue a clammy or glewy substance, yet without any fatnesse or gresinesse at all. Wherefore, wherefoeuer in the Body, especially in the outward parts, there gathereth together any such glewy or clammy excrement, there the naturall heat bringeth forth Haires; and this is the cause why in the Arme-holes and about the Priuy-parts, yea and in all the rest of the Body Haires grow plentifully. Now that part of the Haire that is impacted in the Pores of the Skin, may fitly be resembled to the root of an Hearbe sticking in the Ground, and that which beareth out of the Skin, to the Hearbe it selfe.

There is also required a conuenient place, as a foundation wherein the roots of the Haires may be established, and that is the Skin, which of all other parts is fittest for their breeding, saith *Galen* in the first Chapter of the second Booke *De Temperamentis*, because it is neither too dry nor too moist; for as neither in Ground where water alwayes standeth, nor in Ground that is ouer-dry and worne out of heart can any thing be brought forth: so in an ouer-moist or ouer-dry Skin no Haire can grow. For though the Skin be accounted dry, yet in a Man it is not without some moisture, as it is in those Creatures which are couered ouer with a stony or crusty Shell; as Oysters, Lobsters, Crabs and such like; and in such as lurke in Dens, as Snakes; and those that haue Scales, as Fishes; in all which Haire cannot grow, because their Skins are truly and altogether dry. Moreover, the Skin ought not to be too soft and moist, like Cheese new curded; for then it would not hold the roots of the Haire because of his thinnesse; and beside, after the Pores were as it were bored by the excrement, they would fall together again, the parts being so fluid that they would run into one another and be exquisitely revnited: But it must be moderately dry to hold the Haire to his root, and moderately hard, not vnlike a Cheese already well gathered & somewhat pressed, for so it will be better thrilled and perforated by the issuing humour; which perforations also will remaine and continue, the dry Body not suffering the parts to revnite, but to consist as they are, and so by the continuall exiture of the matter, the Pores will be more neatly fistulated. Wherefore considering the whole Skin is full of Pores, whereout something is continually breathed by the naturall heat which disperseth, attenuateth and carryeth away with it selfe no small part of the inward moisture, it followeth, that in all parts of the Body the Haires may issue forth, euerie Pore hauing a Haire in it to keepe it open, for the better breathing or thrusting out of exhalations: Yet we must except the Skin of the Palmes and Soales of the Hands and Feet, because in them there is a large Tendon immediately vnder the Skin, which being exceeding thicke & dry, makes it vncapable of Haires; but I cannot admit of that reason, seeing a Hare hath also that broad Tendon, and yet hath not those parts void of Haire. Therefore we say that Nature hath made those parts hairelesse, both for vse that they might be the more sensible, as also for motion.

Now that Thinnesse of the Skin is required for the production of Haires, it appeareth by the example of Scars; for if you raise a blister by scorching the vpper Skin or Cuticle, after it is healed and the vpper Skin is growne thicke, no Haire will rise out of the Scarre, because it hath no Pores in it.

The Haires be of two kinds, some are *congeniti*, that is, *Congeniti*, bred with vs, as the Haire of the Head, of the Eye-browes, of the Eye-lids. These are bred in the Child while it is yet in the Wombe, and are resembled not vnto Hearbs that grow by sowing, but vnto such Plants as Nature bringeth forth of her owne accord; and such doe not necessarily follow the temperature of the Body.

Other Haires are called *postgeniti*, that is, *Postgeniti*, bred after the Skin is growne thin, which hapneth in Boyes when they begin to breed Seed, in Girles when their Monthly courses begin to flow; these come out in three places also; first about the Priuities, secondly vnder the Arme-holes, thirdly in the Chin and Cheekes. Those that are gelded before the age of fourteene yeeres, haue no Haires growing on their Chin: the reason is, because the wayes of the Seed are not opened, & by castration are after intercepted; and therefore the Skin doth not rarifie: If after those Haires be growne the Testicles be taken away, those Haires also fall, excepting in the Groyne. Againe, in Women those Haires which we called *Postgeniti*, doe arise later, neuer in the Chin, because there is not so great agitation of the

the humor in the act of generation in women as can rarifie the skin so farre from the place where the seed is engendred; and yet we see, that in some women after their Courses are staide, the haire begins to bud on their chins. It may also fall out, that both men and women may be without any of the *postgeniti* by some naturall defect, contracted in their generation.

Why women
haue no beards

The forme of the haire is expressed by certaine accidents; for they do vary in thicknesse and thinnesse, hardnesse and softnesse, length and shortnesse, streightnesse and curlednesse, multitude or scarcity, as also according to the quality of the skin, and the naturall propriety or condition of the parts in which they are fixed. Moreover, they differ in colours, whitenesse and blacknesse, and middle colours between them; so also by reason of age, and growth of the body. The chiefe cause of their thicknesse and thinnesse is the skin, saith *Aristotle*, 5. gener. *Animal*. 3, which in some is thicke, and in others thin; in some rare, and in others thight and compact. Another cause is the variety of the moysture lying vnder the skin, for in some it is clammy, in others waterish: so out of a thicke skin, thicke and hard haire, and out of a thin skin, thin and slender haire are produced.

The formes
of the haire,
and the causes
of them all.
Their colours

The causes of
their crass-
tude.

And if the skin be rare and thicke, the haire is also thicke, by reason of the abundance of earthy substance, and the laxity of the passages. But if the skin be more thight and compact though it be thicke, they come out thinne, by reason of the narrownesse of the passages. So if the vapour whereof they are bred be waterish, because it is quickly dried vp, they grow not much in length; but if it bee clammy and glutinous, because it is not easily dried vp, they extend themselves in length. So that the cause of the length and shortnesse of haire, is the abundance or scarcity of the humor wherewith they are fed. And hence it is, that the haire of the head are the longest of all the body, because the Braine affordeth a great deale of a clammy moysture, and because the braine is bigger then the other Glandules; they are also crasse or thicke, because the skin of the heade is exceeding thicke, yet rare and containing much moysture. The haire of the head in Latine, are called *Capilli, quasi capitis pili*: in Greeke *κῆρυς*, from *καίρω*, which signifieth to cut. In men they are called *Casaries à frequenti casione*, because they are often cut; and in Women *Coma*, because they bestow great paines in combing and curling them. They are also in Women diuided by a line, which in Greeke is called *λίσσιμα*, in Latine *discrimen*, in English the *shed*. Now the haire is either straight or curled, by reason of the exhalation it selfe, or of the pores whereout they passe: Of the exhalation which beeing smoaky, by heate and drought maketh the haire curled. For that smoaky soote hath a double course, the earthy and dry part downeward, the hot part vpward; hence it boweth not downe right, but wrinkingly, because there is in it but little moysture and much dry and earthy matter; and this we may perceiue, if we parch haire in the Sun, or neare the fire; for the crisping of the haire is as it were a kinde of convulsion because it wanteth moysture; or else we may say, the haire curleth by reason of the drynesse of the temper; and therefore all Black-Moore haue curled or crisped haire.

Of their
length.
The haire of
the head are
the longest:

The names of
the haire of
the head.

The causes of
the streitnesse
or curling of
the haire.

Secondly, by reason of the constitution of the pores wherein the haire are implanted. For when the exhalation is so weake, as that it cannot make a straight way for it selfe, it giueth a forme to the pore answerable to it owne contortions. But if the exhalation be strong enough, yet cannot ascend directly vpwards by reason of the hardnesse of the skin, then it turneth side-long, like as we see the smoake and the flame when it is hindred to mount streight vpwards, diuideth it selfe and turnes aslant. Wherefore both by reason of the imbecility of the exhalation, and of the hardnesse of the skin, the roots of the haire grow awry. Now it standeth with good reason that they should grow and continue still such as they were framed at the roote. For no hard or dry body can be extended streight fourth, vnlesse it be first softened and mollified.

Of Curling

Comparison.

Those that haue abundance of moisture, and the pores streight, haue their haire also streight. Again, long haire is soft, but the curled are hard. Moreover, haire encrease and grow more or lesse according to the Nature of the skin, and the condition of the parts where they are implanted. In the head they grow in greatest length and abundance, next in the Beard, because that is moderately hot and dry, especially when the haire are fine and slender. But the haire of the eye-browes and of the eye-lids, are small and grow not almost at all; but for the most part, keepe alwaies an equall magnitude, and seldome fall, because they haue vnder them a hard body, like vnto a gristle. For those haire that spring from soft and moderately moyst parts, encrease very much, as those of the head and the beard;

Of streight
haire.

The Beard.

beard : and *Galen* addeth those of the arme-pits, and about the priuities : but those that arise out of hard and dry places, are small and almost of no growth : yet in some the eye-browes grow so hairy in olde age, as that they are constrained to cut them, or else they would offend their eyes. Haire buddeth in the chin, when the skin beginneth to rarifie or grow thin ; the matter of it is a moysture sent thither from the head, as *Hippocrates* holdeth in his Booke *de Natur a pueri*, and these haire make the Beard, which is not alike in euer man ; for some about their chin and lips haue great store of haire, some haue no haire there, but very much on their cheekes.

Aristotle in the third Booke *de Histor. Animal.* the 11. chapter saith, that the haire vse to grow extraordinarily in some diseases, especially in consumptions, we may adde the *Plica Polonorum*; he addeth also, in old bodies and dead corpes they receiue augmentation both in length and thickeffe, but do not spring a new.

The causes of the colours of the haire.

*Hippocrates.**De Nat. pueri.*

The humour.

Galen.

When Blacke.

Reddish.

White.

They vary likewise in colour, and are answerable to the predominant humor, for such as the humor is which the flesh draweth vnto it (saith *Hippocrates*,) such also is the colour of the haire.

Galen in his second Booke *de Temperamentis*, and the fift Chapter, saith, that the haire becomes blacke, when the vaporious excrement scorched by the heate is changed into a perfect soote ; and somewhat red, when the excrement impacted in the passage is not yet altogether growne black ; but yellow, when the vapour is lesse scorched ; for the excrement that is so impacted, proceedeth of yellow and not of blacke Choller. White haire are made of Flegme, and the colours betwixt these of a mixture of Flegme and choller.

Why mens haire are not of the colour of their skin.

But a question may be asked, why in Beasts the colour of the haire followeth the colour of the skin ; and in men it is far otherwise ; for the whitest men and women, haue often haire coale blacke. *Aristotle* maketh answer 5. *de generatione Animal.* 3. and 3. *Histor.* 11. Because, saith he, a mans skin is thinner then the skin of any other Creatures of his magnitude ; and therefore the skin cannot afford any matter of haire of it selfe, or retaine the excrement driven to it so long as to giue it his owne colour.

The Region.

The haire varieth also by reason of the region and the diuerse dispositions of the ambient ayre ; so those that inhabite a hot and dry country, haue hard, blacke, dry, curled and brittle haire, and of small growth, as the Egyptians, Arabians and Indians : contrariwise those that inhabit in a moyst and cold climate haue soft haire which grow moderately, are small or fine, straight and reddish, as the Illyrians, Germans, Sarmatians and al the coast of Scythia, as *Galen* saith. But such as inhabit a temperate tract between these, haue hayre of greater growth, exceeding strong and somewhat blacke, moderately thicke, neither altogether curled, nor altogether straight.

How haire alter according to ages.

They vary also by reason of age; for little childreh haue little haire, because as yet their skin hath no pores, nor any sooty excrement applying vnto it : when they begin to cotten, which is about xii. and xiiii. yeares of age, their haire are small and weake ; but as their youth growes strong, and their flourishes grow vpon them, which is towards xv. and xviii. then their haire grow many, great and strong, as well because their skin is growne full of pores, as also for that they abound with sooty excrements.

*Hippocrates.**De Nat. pueri.*

The reason of baldnesse.

Those that are well in yeares haue hard haire, because their skin becomes hard and thicke in old age, by reason of their coldnesse and siccity. So we see some men when they grow in yeares, become bald either for want of hot and clammy moisture, or because naturally and originally their skin was somewhat too dry, or else as *Hippocrates* saith, because they abound with Flegme, which being stirred in their heads by carnall copulation, and so growing hot ; when it arises into the skin, it scorcherh the roots of the haire and so causeth them to fall off, for it is an old saying *Nemo Caluus ante Coitum*. And that is the reason also why neither Eunuches nor children vse to growne balde. Now this baldnesse begins commonly in the forepart of the head, because (saith *Aristotle* 5. *generat. Animal.* 3.) it is dryest, for there the skinne lyeth vpon the bare-bone, without any interposition of fatte, as it is in the Nowle.

Why old men grow gray.

In like manner, Men growing old become gray-headed; not by reason of drought, for we see often that many haire become gray together, but nothing can vpon a suddaine become dry ; the true cause is putrifaction for want of ventilation, and therefore those that haue their heads continually couered, grow sooner hoary then others, as *Aristotle* obserued. *Galen* in his second Booke *de Temperam.* and the 5. chapter, saith, that before the skin of the head is growne to extreame drynesse, the haire become weake for want of

3 *Hist. Animal.*

COR-

conuenient Food, and white because the nourishment wherewith they are fed, is as it were the dregges of Flegme, which in proceſſe of time remaining about the Skin, doe putrifie.

Of all parts the Temples are firſt hairie, because they are verie moyſt by reaſon of the great Temporall Muſcles which lie vnder them. Now euerie Muſcle is fleſhy, and Fleſh is moyſter then either Bone or Skin. Next vnto them, the Fore-part of the Head growes white; laſt of all, the Haire about the Priuities and the Eye-lids; but no Body growes bald in the Temples or in the hinder-part or Nowle of the Head, vnleſſe it be Women that weare it off with Wires, &c.

The Haires are fed by moiſture, therefore *Hippocrates* ſaith, they grow moſt plentifully where they find moderate moiſture for their Food, which *Aristotle* ſaith, is diſpoſed at their root; for if you plucke them vp, that moiſture is drawne vp with them: Beſides, the Haire is thicker at the root then in the reſt of his length, because it hath ſome of that moiſture newly applyed to it. From theſe humors are exhalations raiſed, & Nature turnes the thickeſt and the clammieſt of the excrements into nourishment of the Haires. Therefore when they are well fed, and with laudable Aliment, they encrease apace, and are moderately craſſe or thicke. But when they are cut, they doe not begin to grow vp againe where the Sheeres diuided them, but at the root, from whence they iſſue, and ſo they encrease and are nourished by appoſition, as the Teeth are; not by the excrements of faultie and vicious humors, but by excrements of the third concoction: Otherwiſe, they would not fall off, but rather encrease in thoſe that haue the *French* diſeaſe and the Leproſie, conſidering that in ſuch Bodies the excrements of vicious humors are exceeding abundant.

How Haires
are nourished.

The uſe of Haires in generall is foure-fold: Firſt for a couer; ſecondly for a defence; thirdly for an ornament vnto the parts vnder them; fourthly to conſume and waſt away the thicke and *fuliginous* or ſootie excrements. So the Haires of the Head which are in great abundance (for of all Creatures a Man hath moſt Haire on his Head) doe couer the Braine, and ſhelter it from ouer-much cold or heat. For Mans braine being in proportion greater and moiſter then any other Creatures, it requireth accordingly a more carefull guard and preſeruation; for that which is the moiſteſt will moſt eaſily grow hot & cold againe. And because the Braine is ſeated farre from the fountaine of heat, and neere vnto the Bones, and vnder them is not couered with any fatneſſe; the Haires are provided both to fence it, and to keepe it warme. They alſo waſt and conſume the thicker excrements; and because it is not behoofefull for vs that we keepe our Heads alike couered in all ages of our life, times of the yeere, Countreys and conſtitutions of Bodies; therefore we may fit our ſelues vnto the times, and weare them either longer or ſhorter; but if they be altogether ſhauen off, they proue the cauſe of deſluxions. The Haires of the Head haue not onely this uſe to couer the Cheekes and Chin (which Women doe with Veiles and Maskes) but alſo they ſerue for Ornament. For it is a venerable ſight to ſee a Man when he is come to the yeeres fit for it, to haue his Face compaſſed about with thicke and comely Haire. Nature therefore hath made the vpper part of the Cheeke and the Noſe without Haire, leaſt the whole Face ſhould be wild and fearce, vnbeſeeming a mild & ſociable Creature ſuch as a Man is. In Women the ſmoothneſſe of their Face is their proper Ornament; they needed no Enſigne of Maieſtie because they were borne to ſubiection. And Nature hath giuen them ſuch a forme of Body as is answerable to the diſpoſition of their mind. To conclude, the uſe of Haire is diuers, according to the ſeueral places where they are: as for example, the Haire of the Eye-browes ſerue to receiue the humour falling downe from the Head, and thoſe of the Eye-lids to direct the Sight, and ſo of the reſt.

Creature.

CHAP. V.

Of the Cuticle or Scarfe-skin.

THE firſt containing or inueſting part, is the Cuticle, which the *Greekes* call *Epidermis*, because it runs vpon the ſurface of the true Skin; whereof it is as it were a flowing or creamy production. For whileſt Nature in the generation of the Skin mingleth Blood with the Seed, a moiſt vapour of the Blood foaming or frothing vp, and driuen forth by the ſtrength of the heat, is condenſed or thickned by the coldneſſe of the Aire, and turned into a Cuticle or Scarfe-skin, for ſo I thinke we may properly call it.

How it is
generated.

And

Why new-
borne Infants
lookes red.

And this is the reason why in Infants new-borne, the whole Skin looketh red, the Cuticle not being yet formed for want of cold Aire; or at least not sufficiently condensed, as it is after a short time; the Aire thickning the creame or froth of the Blood, as we see in Gruell or boyling of Past or Starch, a Skin, filme or phlegme gathered together of the vaporous froth that ariseth from the thicke moisture which is by the cold Aire condensed.

It will not
grow vpon
a Scarre.

This Skarfe-skin is easily lost by attrition or scalding, and ariseth apparently from the Skin; it is likewise as easily recovered where the Skin remaineth sound (for where there is no Skin, but onely a Scar or Cicatrice, there it will not grow againe) and therefore it is no Spermaticall part, because if they perish, they can very hardly againe be restored.

Why thin.

It is wondrous thin (vnlesse it grow *Callus* or hard by continuall labour, as we see it doth in Felt-makers) that it should not dull the sense of the Skin vnder it: Yet in the Palmes of the Hands, and the Soales of the Feet, where it is continually worne and renewed againe, it is more crasse and thicke. This is that which Serpents cast euerie yeere, we call it the Slough; Men neuer, but vpon long sicknesse or poysons, or the vse of flabbering complexions. It is thighter or more compact then the Skin it selfe, whence it is, that those watery humours which are thrust out from the Center to the Circumference of the Body, doe easily passe through the Skin, but hang often in the Cuticle, and generate *Echymata*, *Phlyctides*, and those many watrish *Pustles* which are called *Hydroa*. It is altogether without Blood, because it receiueth neither Veine nor Arterie, so that it encreaseth rather by a kind of addition of matter, then by Nutrition.

Skin.
*Medium
tactus.*
*Lib. 2. De
Anim.*
Text. 114.

Insensible it is, that it might defend the Skin vnder it from externall iniuries; as also attemper the exquisite sense of the same, and so becommeth *Medium tactus*, the *Meane of touching*. For, saith *Aristotle*, all sensation is made by some *Meane*, none by the immediate touch of the object and the instrument. Hence it is that a Man cannot see to read vpon a Booke that is layd vpon his Eye; because there wanteth the Meane betweene the object and the instrument of Sense, that is, Aire enlightned. In like manner, when the Cuticle is off, we cannot distinguish betweene one Temper and another; because the very gentlest touch of the bared Skin breedeth paine, and the sensation is confused, which is distinct when the Scarfe-skin is whole.

There is also another vse of it, to cover the open ends of the *Capillary* or hairie Veines which doe determine in the Skin: For if the Cuticle be taken off, the Skin vnder doth bleed. Moreouer, it is also a couering to the Skin, that the moisture might not indecently or vnprofitably well or issue out at all times; for in a Gall or Rub, which is called *Intertrigo* in which the Cuticle is separated, the Skin is euer moist.

Lastly, it sootheth and polisheth the roughnesse and inequality of the Skin, making it soft, supple and slicke, and so becommeth one of the greatest beauties that Nature hath giuen to the Body of Man. That I cannot but wonder at *Columbus*, who vtterly forgot the manifold vses of this Cuticle.

CHAP. VI.

Of the Skinne.

The names of
the Skin.

His substance.

Whereof it
is made.
Vesalius.
Galen.

Columbus.
Varolius.

Vnder this Curtaine or Skarfe, lyeth the true and genuine Skin which the *Greekes* call *ἡ δερμὶς*, because it may be excoriated or flayed off, so *Hippocrates* in his Booke *De Arte*; but in his Booke *De Insomnijs*, *ὑπόμνημα*; and *De victus ratione in acutis*, *εσπίριον*; and *De Ossium Natura*, *ἡ δερμὶς quasi ἡ δερμὶς*, a Band, because it compasseth and knitteth together the whole Body; in *Latine* it is called *Cutis*. It hath a substance proper to it selfe, although it be very like to a Sinew & Membrane, because it is white, will stretch, and is of exquisite sense; but it is thicker then any Membrane. It is ingendred of Seed perfectly mixed with Blood, whence it commeth to passe that by it we may iudge as well of the Spermaticall as of the Bloody parts. It seemeth therefore to be of a middle nature betwixt Flesh and a Sinew, and so *Vesalius* conceiueth it, not so abounding with Blood as Flesh, but as it were a bloody Sinew; so saith *Galen* in his first Booke *De Temperam.* Notwithstanding, in the composition the Spermaticall part exceedeth the Sanguine, which appeareth as by the colour, so by this, that being wounded it is only revmited or conioyned by a Cicatrice or scar. *Columbus* thought it was bred of the extremities or ends of the Vessels dilated; *Varolius* onely

onely of the softer Sinews, which attaining to the surface of the Body, doe there grow together into a covering, receiuing addition from the affluence of Blood; as the broad leaues of Water-Lillies arising from a slender stem, when they appeare aboue the Water, are extended into a great bredth out of a small stalke. *Galen* in the third of his Method, saith, it is bred of the dried and constringed or writhen Flesh vnder it; and that is the reason why no Haires will grow vpon Scars, because they haue no foundation for them as the true Skin hath: But it should seeme that herein *Galen*, and not he onely, but *Plato* and *Aristotle* were somewhat mistaken: For the Skin may be flayed from the Flesh vnder it, yea and between the Skin and the Flesh there are two parts (if at least they may be so called) the Fat and the fleshy Membrane.

The Skin is naturally white, but according to the humors that abound, or the bodies vnder it, saith *Hippocrates* in his Booke *De Succis*, it varieth the colour. For example: where Blood aboundeth and the Skin is thin as in the Face, there a Rosie rednesse mingleth it selfe with the white, or ouercommeth it, especially if either by heat or motion of the mind it flow to the place more plentifully; and this Blood when it is condensed or thickned by cold, maketh the Skin looke liuid or blew. In Chollericke Men the Skin is pallid or yellowish: In Melancholly swartie and blackish or dusky, but if it be defiled with vitiated humors, it becommeth yellow and blacke in the Jaundise and Morpew.

It altereth also his color, by reason of bodies vnder it; so where it adhereth or cleaueth to the Flesh, as in the Bals of the Cheekes and Palmes of the Hands, it sooner becommeth red; if to the fat, it is whiter and smoother, especially where the fat is more plentiful; but when that fat is consumed, the Skin becommeth wrinkled and looketh like a dusky shadow; as also it is liuid or blewish where greater Veines are branched vnder it. Furthermore, the Skin that it might be a kind of muniment or defence is thicke, though not so thicke as in other creatures. It cannot without extreme paine be separated from the Flesh, because the extremities or ends of the Vessels doe determine in it; whence some haue thought, that it proceedeth from those extremities of the Vessels dilated or spread into a superficies or smooth plainnesse. It is soft and of exquisite sense, by which it fore-warneth the inward parts of the approaching euill before it ouertake them.

According to the diuers vse of the parts, it is either softer or thinner, as in the Face, the Yard, and the *Scrotum* or Cod; or harder, as in the Necke, the Backe, the Legs & the Soales of the Feet; some of it is in a middle temper between hard and soft, as in the Palme of the Hand, and especially in the Fingers ends, because they are ordained to apprehend with; and beside in the Skin of the Hand, the power or sense of feeling was to be perfect, and therefore it behoueth that it should be void of all excesse, & most temperate of all others; because that which is the iudge of feeling as all other Instruments, must be free from any foraine or externall qualitie whereby the Iudgement might be preiudiced: So some part of the Skin is exceeding thicke, as in the Head; some part onely thicke, as in the Necke; some part thin, as in the Sides and Soales of the Feet, which is the reason that there Men are ticklish; some part yet thinner, as in the Palme of the Hand; and some thinnest of all, as in the Lippes.

It hath also a diuers connexion to diuers parts: For somewhere it may be easily separated, as in the vpper and middle Venter, the Armes and the Legs; otherwhere very hardly, because of the fleshy Membrane to which it is tyed by the mediation of certaine Fibres and Vessels, betweene which and the said Membrane, the fat where it is, so interposeth it selfe, that the Skin may more easily be flayed from it: But from some parts it can hardly or not at all be separated, as from the Soales of the Feet, and the Palmes of the Hand, to which it is immediately conioyned, that the apprehension of those parts may be more firme & stable. It is also very hardly separated from the Flesh of the Fore-head, and almost of the whole Face, especially of the Eares and Lippes, because of Tendons and Muscles; especially that which they call the *Broad Muscle* mingled therewith. Finally, in the Forehead it is mouable, in the rest of the Body (of a Man I meane) immouable, or for the most part: For in Beasts it is almost all wayes mouable, and they say, an Elephant can by the corrugation or wrinkling of his Skin, kill the Flyes that molest him.

It is an vnseamed Garment covering the whole Body, yet hath it certaine breaches made by Nature for her ease and reliefe, partly manifest, which are not many, and are called *Foramina* or Outlets; partly insensible, which are infinite, called *Pori*, and of vs Pores. All which serue either for receiuing in or letting out, or both as need shall require.

Plato, Aristotle

The colour felloweth the humour.

What parts of the Skin are thin and thick

The connexion of the Skin.

Where the fat interposeth it maketh the Skin more easie to flay.

Where the Skin is mouable.

The passages of the Skin.

The passages
or out-lets of
the Skin.

The *Foramina* or passages and outlets are these: about the Eyes for the help of the sight, the thwart holes of the Eye-brows; about the Eares for the hearing, that as well the diuersities of sounds might be let in, as also the Excrements or waxe of the Eares be auoyded out; about the Nofethrils for a helpe to respiration and to smelling, and the conueying away of the Mucous or slimy excrement of the Braine: the Mouth is open to receiue meats and drinckes, and sometime againe to vomit. The Nipples of the Breast ought necessarily to be perforated, that by them the Infant might sucke Milke from the Mother: the Nut of the Yard for the emission of Seed and Vrine; the Port *Esquiline* or Siege, that the noysome Excrements may be conueyed out of the Body. In Women the *Lap* of the Wombe, as well for the admission of the part of Generation, as for the bringing the Infant into the world, and to auoid the Vrine and the Monthly courses. In the Infant the Nauill that it might receiue Blood and Spirits to supply it with nourishment and life. Finally, in the Fingers ends where the *Nayles* are affixed it is also perforated, out of all which parts we haue knowne Blood to issue in a cruell disease.

The Pores.

Transpiration

The Pores are abundant like to the Pin-hoales of a Syue or Searce, as is manifest by the sweat and hayre that breathes and breakes out, in which regard *Plato* compares it to a Fish-net: and these parts are the way of transpiration, that the excrements of the third concoction which haue no other, might this way haue egress or auoydance; whence of some it is called the *Vniuersall Emunctorie* or Draught, because it receiue all the superfluities of the inward parts. These Pores are small and almost insensible, lest otherwise there should be too free a dissipation of the Spirits, yet in some Bodies they are narrower or straiter, in some wider, and such doe easily melt away in sweat, and are lesse affected with inward causes: the other sweat verie difficultly, and because the excrements are retained, doe easily incur diseases thereby.

Why the hairs
are set in the
Cuticle.

How some
Bands or ryes
in deligations
of parts be-
come bloody.

That these Pores may be kept open, Nature hath assigned to euerie one a Hayre (of which we haue spoken already) which is fastened in the Pore with a slimy white root, excepting those places where they are continually worne off, as in the Palmes of the Hands. These Pores are the cause that the *Bands* in some deligations become bloody, and sometime pure Blood hath auoided by them, as in the *English-sweat*. By these also some thinke the Spirits do poure themselves forth in profuse ioy, and the more liberall vse of Saffron & other Diaphoreticke or sweating Medicines, by both which they are exceedingly relaxed.

That this Skin may be nourished, that it may liue and haue sense, it receiue all these three common Organs or Instruments of nourishment, life and sense; Veines, Arteries and Sinewes; whose diuarcations and diuers branchings, we shall shew in fitter place in our discourse of the Vessels.

The vses of
the Skin.

The vses of the Skin are, first that it should be the immediate Instrument of outward touching, that we might be fore-warned of outward iniuries before they come to hurt the inward parts, like as the Membranes are the Organs of the inward touching or sensation. Moreouer, it is ordained to be the common and natiue Vestment or Mantle of the whole Body; a Muniment beside and a comly Ornament compassing and couering it on all sides, that the Vessels might more securely run vnder it: The Muscles and Entrails be contained in their proper places, and defended from heat and cold, and finally, the naturall heat detained from ouer-free effluxion or expence.

CHAP. VII.

Of the Fat.

The Fat,
whereof
is engendred.

HE Fat called in *Greeke* *σμηλν*, in *Latin* *Pinguedo*, in Man is bedded betwixt the Skin and the fleshy Membrane, but in Beasts it is vnder the Membrane also. It is engendred of the more oily, thin and airy portion of pure and absolutely labored and concocted Blood, distilling like a dew out of the small and capillarie Veines of the habite of the Body: which Blood is curdled by a moderate heat (for a burning heat would consume it, and a weake heat would not concoct it) and the densitie or fastnesse of the Membrane; which is the reason that Beasts grow fattest in Winter when their Skins are more condensed with the cold.

This Membrane is Nervous, thin and very fast or thight, and vnder the Skin incloseth all the

the Body, that all that oily matter rarified into vapors, which slippeth by the inward Membranes, may light vpon and cleaue vnto this, and so be turned into Fat, that nothing profitable might be lost. The manner of this worke of Nature we haue in distillations, where though the Still-head be very hot, yet because of his sadnesse or densitie, the vapors which were rayfed vp by the heat of the fire are thickned into water.

The Fat of a Man is lesse white then of any other Creature; for the white Membranes by which the Blood (which is his matter) passeth, doe alter it but a little, so that it becometh often yellower then white.

There be some parts, there be also some ages which want this Fat; for those parts whose bending and extension it might annoy are better without it, as the Membranes of the Braine, the Eye-browes, the Yard, the Cod and the Stones or Testicles: Whereupon some haue excluded it out of the number of the Containing or Inuesting parts. In those parts where it is, it differeth in hardnesse and softnesse; for in parts that are to be moued more violently, it is harder and wouen with Fibres and small Veines; as in the Palme of the Hand, the inside of the Fingers-ends (where there is more need of it to moysten the manifold Tendons and Vessels that there are gathered, to fill vp the emptie spaces and make the Skin more euen & equall for better apprehension) the Soale of the Foot especially in the Heele, that we might more steadily rest vpon it. Sometimes it is alone, sometimes together with a crassie and slimy humor, which stands in stead of Tallow to fit the parts better for motion and to hinder their exsiccation or drying.

In other parts it is softer and yellowish; so it is very sparingly affixed to the out-sides of the Hands and Feet: In the Buttocks because there is more vse of it, it is more copious or plentifull. In cold and moyst Bodyes, as in Men and Hogges it is abundant (whence *Galen* saith that a Woman is fatter then a Man) as also in them that lead an idle and sedentary life. In hot and dry, as Apes and Hounds, it is either none at all or of no quantitie. In new-born Creatures none at all; in those that are consumed with Famine, with Disease, or with Age verie little.

This Fat which in horned Beasts is called *Seame*, in Swine *Lard*, differeth from the *Grease* which in *Greece* is called *siap*, in *Latine* *Adeps*, as *Aristotle* and *Galen* teach; because this Fat is softer and moyster, and is easily melted, and being melted doth not easily clod together againe; but the *Adeps* or *Grease* is harder and dryer, not so easily melted, and suddainly congealed againe, and therefore is more plentifull in those Creatures whose natures are altogether earthy and dry, and those that are more moyst haue abundance of the Fat we call *Pinguedo*. Men haue much of this Fat vnder their Skin, because the matter of it is retained by the soliditie and thicknesse of the same, for so we see that those Creatures that haue the fastest Skins are the fattest, as Swine and Dolphins. Now the *Adeps* or *Grease* in a Man is in his Kall, Kidneys, Heart, Eyes, the Ioynts of the Bones, betwixt the broad Tendon and the Skin of the middle of the Palme of the Hands, in the inside of the Fingers and the Toes.

The vses of this Fat are: First, It is a defence to the parts to which it is allowed, so in the Buttocks it serueth vs in stead of a Quishion; in other parts it auaieth much towards their naturall position and free motion, and therefore in those that be Fat indeed, it lyneth the inside of the Muscles as we see in fat Beefes. For the Vessels that run vnto the Skin it is a soft Pillow, so safe-guarding and moystning them, that they be not dried and so distend, or lying bare be broken in peeces; and therefore it is gathered plentifully in those parts where the larger Vessels diuide themselves.

Another vse of it is, to fill vp the emptie distances betwixt the Muscles, Vessels, and the Skin, that so the Body might be plumpe, equall, soft, white and beautifull. Moreover, it serueth for a light couering to warme the Body and to cherish the naturall heat, prohibiting the effluxion of it by his visciditie or sliminesse, and by his thicknesse closing the Pores, that neither in Winter the cold should too freely enter, nor in Summer the heat too frankly euaporate. Finally saith *Galen* in his fourth Booke *De Vsu Partium*, and the eleuenth Chapter, in great Famines and want of sustenance, it is conuerted into Aliment, and becommeth the Fother whereon the naturall heat relieueth it selfe. For being dissolved it acquireth the forme of a Blood-like vapor which returneth into the Veines, and so becommeth for want of better, a subsidiarie nourishment of the parts. The vse of the *Grease* is to moysten and supple the hot and dry parts, as the Heart, to make the motion more glib and agile, and to keepe the Ioynts of the greater Bones and the out-side of some Ligaments, from being exiccated, as also the ends of the Gristles.

the Fat.

The vses of
Adeps.

The Third and Fourth Table shew the Skin-Veines which are opened and scarified: the third those on the Fore-side, the fourth those on the Backe-side: which Veines are for the most parts alike in every body, especially those that use to be opened.

TABVLA. 3.

TABVLA. 4.

1. 1. The second of them, which in the bought of the arme is ioyned with a branch of the liuer veine, and their coniunction is marked with the figure 3.

1. 2. The third is carryed side-long about the radii, and the vpper part of the arme beflowing branches vpon the skin, the chiefest of which neere the bought of the arme runeth outward, but turnes ouer neere the wrist, and there meeteth with the Liuer-vein, marked there in the second figure with a* and a little lower being diuersly deuided nourisheth almost the whole hand.

1. 3. The Liuer veine called *Hea uica*, *Basilica* or the interall veine it is called of some, & in the left arme *Lienaris* or the spleen-veine.

1. 4. A branch from the Liuer-veine deuided into two, nourishing the skinne within and without.

1. 5. A branch going to the muscles of the vpper arme, and the skin on the vpper side.

1. 6. The fore branch of the Liuer vein, which at the bought of the arme is ioyned with a branch of the *Cephalica* marked with v, AA. 2. Branches coming from the veins which two branches make the middle veine named *Mediana*, noted with 3.

1. 7. A branch arising from the former, and passing to the wrist, and on the after wrist meeteth with a branch of the *Cephalica* which are ioyned about the little finger, which coniunction we noted in f. above.

1. 8. Two fore veins of the *Cubite* or lower arme from a branch of the Liuer veine, which being accompanied with nerves, run al along euen through the hand, these where they are marked are sometimes opened in-

Read of the Liuer veine.

3. 1. The middle or common veine made of the branches of the *Cephalica* or head-veine and *Basilica* or Liuer veine.

4. 1. 2. The diuision of this common veine a-boue the wrist, which from 3. to 4. is called the *co non* vein of the cubite or lower arme: but at 4. it is deuided, one part going to the outward side, anyther to the inside and so minglith it selfe with the neighbour veins: this veine is not opened.

5. 2. The outward branch of this partition which watereth the backe of the hand.

6. 2. A branch of the common veine which vnder the thumb is opened for the *Cephalica* or head veine.

7. 2. The veine called *Saluatella*, a branch of the *Cephalica* and *Hepatica*, which about the little finger is opened for the spleen and diseases thereof.

8. 2. A veine between the middle and the ring fingers, which some take to bee that which *Auicenna* calleth *fole*.

9. 2. A branch toward the ring finger.

AA. 2. Branches coming from the veins which about the loynes are produced knottily, these in the loynes are scarified.

B. 1. Branches proceeding from the *Epigastrica* veine, distributed to the four paire of muscles of the *Abdomen*, a notable branch of which is wounded often, when men are cut for the rupture.

CC. 2. Veines coming from the vpper branch of the trunk of the hollow veine called *vena cava*, and are dispersed through the muscles and skin of the buttock.

DD. 1. Veines distributed through the *pecto-*

rall muscles and the breast.

E. 1. Veines reaching to the breasts from the veine called *mammaria*.

FF. 1. Small veins coming out from the veins which are couched vnderneath and go to the chest, the p. in all of these are scarified in the shoulder blades.

1. 1. Certaine small veins reaching to the outside of the belly coming from the veins of the muscles vnderneath.

G. 2. A branch that runs along by the side of the chest.

H. 1. A veine which reacheth to the shoulder, the muscles of the shoulders blade, and the glandules in the arme holes.

II. 1. The inner crural veine springing out neere the leske, goeth vnto the skin to the very foote, hauing a nerue running about him all the way.

KK. 1. Branches of the foresaid veine which by the inside of the thigh, reach vnto the very leske.

LLL. 1. Veines passing vnder the skinne on the fore side of the thigh.

MMMM. 1. 2. The *Crural* veine carried on the inside and outside of the thigh.

NN. 1. 2. The inner leg veine called *Tibia*, which is diuersly carried vnder the skin, and here it may bee opened when we would let blood in it.

OO. 1. The same carried vnto the fore parte of the inward ankle, and then spreadeth it selfe in the vpper part of the foote called *dorsum pedis*.

P. 2. A branch from the vpper *Crural* veine, sending small furcles to the hippe, the muscles of that place and the skin.

1. 1. 2. The outward iugular vein climbing vp the sides of the necke, this can hardly bee opened without danger, but his branches may be scarified in the necke.

b. 1. The place where this veine deuided into 2 branches.

c. 1. The inner branch of the exterior iugular, which going to the muscles of the mouth & the boy *Hyon* is couched vnder the tongue where it is opened in squinches and other diseases of those parts.

d. 1. 2. The vpper branch of the same external iugular that goeth to the back-part of the head.

e. 1. Branches going to the buccae, cheekes and the nose.

f. 1. 2. The fore-head veine, which in the middle of the fore-head where it is wont to bee opened, ioyned with the branch of the same veine on the other side.

g. 2. The veine called *vena pappi*.

h. 2. Veines dispersed along the temples, to which are adioyned portion of the fore-head veine.

i. 1. 2. The veine which goeth to the eares, and watereth the back-part of the head.

k. 1. A branch coming from the vpper part of the axillary vein and going to the more backward muscles of the necke.

l. 1. 2. A branch from the *Cephalica* or head veine, going to the skin and the muscles which lift vp the arme.

mm. 1. 2. The *Cephalique* head or vpper-veine, which passing along the vpper part of the arme accompanied with a nerue, and opened commonly at the vpper bunch of the bought of the arme, but happily it might more safely be opened a little lower where it bendeth from the sinew.

n. 1. Small veins from the *Cephalica* dispersed through the skin of the arme.

o. 2. Branches from the head veine to the shoulder blade, carried betwene the skin and the flesh.

p. 1. The *Cephalica* is here deuided into 3 branches.

q. 1. The first of these branches which goeth to the muscles, arising from the vpper bunch or knot of the vpper part of the arme called *humerus*.

Q. 1. A branch noted with 7, and 9, which befloweth certaine furcles vpon the muscle of the leg, and the skin of the thigh.

RS. 1. A veine from the ioyning of the branches of that other, which passeth to the back muscles and skin of the thigh somewhat vpperward.

TT. 2. The *Ham-veine* *vena popheis*, which runneth most where it is marked, and passeth vnto the calfe of the legge marked with V. 2. where it deuideth it selfe into many branches.

XX. 1. The inner branch of the crural veine going to the muscles and skin of the calfe.

Y. 1. The inner veine of the legge running to the inner side of the foote accompanied with a nerue, this they open vnder the knee instead of the *saphena*.

ZZ. 1. 2. A part of the crural veine going to the backside of the inner ankle: this is called the *saphena*, and is opened vnder the inner ankle in women most what to further their naturall euacuations.

aa. 1. The outward branch of the crural veine or the vpper leg-veine called *Tibia*, which is diuersly branched againe along the outside of the leg and the top of the foote.

C. A part of the foresaid branch climbing along the outward ankle.

yy. 1. Among the veins of the foote, this is that which vnder the name of the *Cephalica* is opened at the great toe, but not without danger, because it hath a nerue ioyned with him.

CHAP. VIII.

Of the Flefhy Membrane.

THE Flefhy Membrane (first fo called by the *Arabians*) or Pannicle, called *Panniculus Carnosus*, in *Greece* *ὑμνὸς ἀρκαδῖος*; is onely flefhy among all the Membranes, and that especially in Beasts. *Galen* calls it *ὑμνὸς*, that is, a Membrane; some call it the Musculous Membrane, because in those Creatures which moue their whole Skin, it is fo be-sprinkled with flefhy Fibres, that it seemes indeed to be a Muscle.

This Membranous part, as all other Membranes, is made of Seed. In a Man it is vnder the Fat, but in Apes, Dogges, Sheepe and such like, it lyeth immediately vnder the Skin. It compasseth the whole Body, and closely cleaueth to the Skin by the mediation of many Veines, but fewer Nerues and Arteries diuersly propagated, and through it climbing vp thither, whereto also helpe the addition of flefhy Fibres. It cleaueth also to the Membranes of the Muscles vnder it, but by more slender Fibres. It is said by some to haue his originall from the Backe, because it cleaueth there most inseparably, and there resembleth the other Membranes; but where it toucheth the Arme-holes, it becommeth in Dogges and Apes very Flefhy, *Galen* saith Musculous.

In Infants it resembleth Flesh altogether, because of the abundance of Blood wherein it is sleept; in growne Bodyes by reason of continuall exiccation, it becommeth like a Membrane, yet so, that in the fore-part of the Necke and in the Forehead, it cleaueth to the Flesh so fast with his flefhy Fibres, that it can vneath be separated, and to the broad Muscle, that it is thought to giue him his Body. It is in a Man (except in the Forehead) immouable; in Beasts it is not onely mouable it selfe, but also maketh the Skin mouable, especially in the Necke, by shaking whereof they driue away the Flyes, but a Horse in shaking of his Skin, will sometime shake an vnskillfull Rider out of his Seat. In the inner part which is next to the Membrane of the Muscles, this flefhy Panicle by reason of a slimy moysture wherewith almost all Membranes are couered, is slippry, that it may not hinder the motion of the Muscles, and it hath an exquisite sense, so that if it be goaded by any sharpe humor, it causeth a rigour or shiuering. The vses of this Membrane are: To compass the whole Body, to couer and defend it: To hinder the Fat from being melted by the continuall motion of the Muscles. It supporteth also, saith *Galen*, 3. *Administrat. Anat.* 2. the Vessels which attaine vnto the Skin, because there passeth betweene it and this Membrane, not only many Capillary and thredty Veines, but also those which we vse to diuide in Blood-letting, together with many Arteries and Sinnews. Finally, it helpeth to consolidate or heale vp the Skin when it is wounded or otherwise violated; for without Flesh it cannot revnite, so saith *Aristotle* in his third Booke *De Historia Animalium*, 11. *wherefoener the Skin is without Flesh, there it cannot revnite being diuided.* In bruit Beasts, the thickenesse and fastnesse of this Membrane, retaineth the bloody vapors, and turneth them into good Blood, and besides it maketh their Skins mouable. And thus much of the Common Containing or Inuesting Parts. But because we made mention euen-now of the Veines which run betweene the Skin and the Flefhy Membrane, which are vsually many of them opened in Phlebotomy; and for that young Chirurgions had need be betimes acquainted with them, we haue here added two Tables and their expositions at large, by which he that listeth may in one view see all the branches of the Skin-Veines how they are seated, and beside learne to call them by their names, that when he is commanded, he may know how to buckle himselfe to his businesse in opening or scarifying of them.

CHAP. IX.

Of the Inuesting or Containing Parts, proper to the Lower Belly.

THE proper Containing Parts whereby the Lower Belly is inuested, are the Muscles of the *Abdomen* or Paunch, and the *Peritonaeum* or Rim of the Belly. The Muscles are in all Bodies alwaies eight, foure on either side, matched equally in Figure, Magnitude, Strength and Action. Of these there are foure Oblique,

Eight Muscles of the Paunch

two Right, and two Transverse, all of them have these appellations from the situation and the texture of their Fibres. In Dissection the Oblique externall paire doe first offer themselves, which are the broadest of all the rest. Next follow the Oblique internall; the Anatomists do usually call the former Oblique Descendents, the latter Oblique Ascendents, but how properly or improperly we shall shew hereafter. Next to these follow the two Right Muscles, in whose inward parts doe appeare those Veines ascending and descending, which conioyne about the Nauill. Vnder all these lye the two Transverse Muscles.

Two other
Muscles lately
found out.

There are also in some Bodies two other small Muscles called *Succenturiati* Assisters, or *Piramidales*, that is, the Spiry-Muscles. The Historie of all these Muscles, as also the Controversies and diuers opinions concerning them, we will at large prosecute in our Booke of Muscles, whether for satisfaction we referre the Reader.

Peritonaeum
or Rim of the
Belly.
The Umbili-
call Vessels.

Next vnder these lyeth the *Peritonaeum* or Rim of the Belly, a thin Membrane like vnto a Spiders Web, which enwrappeth all the inward parts in this Venter contained. Towards the Bladder especiall it is evidently duplicated, betwixt which duplication those Vessels which the Ancients call *Vasa Umbilicalia*, the Vauill Vessels are carried. Of all which it followeth now that we should entreate, beginning with the *Peritonaeum*.

and where
thinner.

THE Muscles of the *Abdomen* and their Tendons being remoued, we meet with a Membrane ingirting the whole cauitie of the Lower Belly, which they call the *Peritonaeum*. Imitating herein *Hippocrates* and *Galen*, who giue it that name, because it compasseth all those parts which lye betweene the Midriffe and the Thighes. Or because it firmeth or strengthneth all the *Viscera* or Entrails that it containeth. The *Arabians* call it *Ziphach*, as they call all other Membranes & particularly *Charmel*, others call it the Membrane or Coat of the *Abdomen*, we call it the Rim of the Belly. The Figure of this Membrane is Ouall, or like an Egge [Tab. 5. AABCD] The greatest it is of all the Membranes of the Belly, as incompassing the greatest cauitie of the whole Body. In longitude and latitude it answereth the whole inferiour Venter. It is made of Spermaticall threds and the Mothers Blood poured betweene them, after the manner of a *Parenchyma*. It proceedeth from the Menings or Membranes of the Braine which inuest the Marrow of the Backe and the Nerues, but hath his beginning betwixt the first and the third Spondell or Racke-Bone of the Loynes; and that is the reason why there it is so thicke that it cannot be separated without tearing in pieces.

It is knit aboue (which part *Galen* 4. *De Vsu Partium* 10. calleth *Vertex Peritonaei*) to the *Diphragma* or Midriffe so strongly, that when it is enflamed the *Hypochondria* are drawne vpward; below to the Bones of the Haunch and Share; before it obstinately cleaueth to the White Line and to the Tendons of the Transverse Muscles; of it selfe alone it consisteth without connexion below the Region of the Nauill at the Share-Bones; and as it applyeth to the Region of the Nauill, it is knit to the thin Tendon of the Transverse Muscles; backward to the originals of the Transverse Muscles and to that Membrane of the Nerues proceeding from the Spondles of the Loynes (from whence some say it ariseth) and to all the *Viscera* or Entrails, to whom it affordeth seuerall Membranes.

His Substance is membranous and thin; *Galen* 4. *De Vsu Partium* 9. addeth simple, yet strong and compact, that when the Belly is full of meat, or the Wombe of the burthen, it might be without danger stretched and relaxed as wide and long as need required. Thin it is before, least it should be a burthen to the parts vnder it; yet so, that in Men it is thicker from the Sword-like Cartilage or Breast-blade as farre as the Nauill, then it is neerer to the Share; but in Women it is stronger from the Share to the Nauill, that it might better endure distention as their burthen groweth. Toward the Backe-Bone about the Loynes it is thicker, because it is to be sluied or parted into many Cobweb-like Membranes, which it affordeth to the Entrails, yet are these very strong that they might be able to containe or keepe downe windy distensions; and least in holding of breath, or when they are stretched they should be broken. On the inside it is smooth, and as it were lined with moysture, that it may not offend the smoothnesse of the Entrails, and sometime hath Grease adioyned to it (which most what accompanieth the Veines) especially about the Stomacke and Holy-Bone. On the out-side it is sharpe

sharpe or harsh and fibrous (saith *Fallopious*) that it may the better cleave to the Muscles. It is euerie where double, which yet is most conspicuous about the *Ridge*; the lower part or Membrane of this duplication, is couched vnder the hollow Veine, the great Arterie, and the Kidneys; all which the vpper and more inward part couereth, that the Vessels being on euerie side guarded and defended, might securely disperse their branches betweene those two Membranes.

The duplication of this Peritonæum

So the *Peritonæum* is doubled, where the Nauell Vessels passe through it on this manner. The two Arteries [Tab. 6. a a] arise from below to the [Tab. 6. C] Nauell; and the Veine ascendeth also from the Nauell [Tab. 6. from D to the upper B] to the Liuer. It is also manifestly duplicated in the *Hypogastrium* or Water-courie, and maketh there a large cauitie, that betwixt his Membranes the Bladder might be inclosed. To which Membrane it is also firmly connexed. [Tab. 2. Lib. 3. at *]

How and where it is perforated.

The first Figure sheweth the Right Muscles of the Lower Belly, with the Vessels, and the Lower Belly it selfe covered with the Peritonæum or Rim, all the Muscles being taken away.

The second Figure shewes the Veines and Arteries which descend from the Mammariæ vessels, and those which ascend from the Epigastricke.

TAB. V.

- A B C D. The vpper, lower and laterall parts of the *Peritonæum*.
 E E. The White Line from the Gristle of the Breast-Bone, called the Breast-Blade, to the Commissure or meeting of the Share-Bones.
 F. The Gristle of the Breast-Bone, *Costi-ago ensi-formis* or the Breast-Blade.
 G. The Nauell which, all the Muscles being taken away, must be kept for the demonstration of the Vmbilicall Vessels.
 H H. The productions of the *Peritonæum* which containe the Seminarie Vessels on either side.
 *. The hole which giueth way to the Seminarie Vessels of Men.
 I I. A Veine and an Arterie from the *Epigastricke*, which being carried vpward vnder the right Muscles, doe here hang down, and are distributed into the lower part of the *Abdomen*.
 K K. A Veine and an Arterie from the internall Mammariæ proceeding from vnder the Bone of the Breast, are carried downward thorough the right Muscles and are diffeminated into the vpper part of the *Abdomen*.
 1, 2. The place wherein the right Muscles arise, which being here cut off, doe hang downe, that their Vessels may the better be seene.
 3, 4. The *Anastomosis* or inoculation of the foresaid Vessels, making the consent of the *Abdomen* and the Nose, and of the Wombe with the Breasts, as some thinke.
 L L. Branches of Veines running into the sides of the *Peritonæum*.
 N. The place of the Haunch-Bone bared, to which the Oblique and the Transuerse Muscles doe grow.

The second Figure.

- a. The descending Vessels proceeding from the Trunke of the hollow Veine, and the great Arterie vnder the Breast-Bone
 b. The Vessels ascending from the *Epigastricke* Vessels.
 c c c. *Anastomosis* or the inoculations of the ascending Vessels with the descending.

It is perforated as the Vessels are necessarily to passe through it, but so as the Orifices or Verges of the Membrane are closed about the Vessels. Aboue, where it cleaueth to the Midriff, it hath three Perforations, one on the Right-hand for the passage of the hollow Veine. Another on the Left, that through it the Gullet might be ioyned to the Stomacke, together with the Sinnewes that cleave vnto it. A third, for the conueying through the great Arterie, the vnmated Veine & the Sinnew of the sixth paire. Below, it is perforated about the Siedge, the Neckes of the Bladder and the Wombe, as also where the Veines, Arteries

Arteries and Sinnewes which are sent into the Thighes, are distributed thorow the *Peritoneum* it selfe, the Muscles of the *Abdomen* and the Skin. There are also two productions [Tab. 5. H H] on either side one, which passing from his externall Membrane seated vnder the Kidneys neere the Share-Bone, like loose Canels or Pipes, attaine through the Tendons of the Oblique and Transuerſe Muscles without the cauitie of the Belly into the Cod, and so to the Testicles, where spreading themselves, they compose or frame their proper Coat. Through which productions the preparing Spermaticke Vessels doe descend, and the *Deferentia* or leading Vessels doe returne to the necke of the Bladder together with the Muscles of the Testicles in Men. But in Women two Processes or Productions passe from the Wombe to the vpper patt of the necke of the same. To these Productions adhereth very closely the internall Membrane, which yet is disioyned neere the Share-Bone; which inward Membrane if it be broken, and the externall dilated, according as the Gut or the Kall shall fall downe either in Men or Women; so it causeth the one kind of rupture or the other. This Production (the Skin being cut in the Flanke) if it be intercepted and taken vp with a tye close to the *Abdomen*, hindreth indeed the fall of the Gut or Kall, but because the Spermaticall Vessels also in Men are necessarily tyed with the Production, the Testicle of that side must needs be vitiated and loose his vse; but if the tye be not [at * * in Tab. 5.] very neere to the *Abdomen*, then some part of the Gut falling downe, brings great moleſtation, and although there be no outward tumifying or bearing down to be seene nor scarcely any can be felt; yet it requireth a new incision & a new tye, as we haue learned at the price of other Mens experience. Finally, in the fore-part about the middle of the Belly where the Nauill is, it is perforated in the Infant for the passage of the Nauill Vessels, that it may receiue nourishment from the Mother, but afterward that Perforation groweth vp, and if it breake out againe, it causeth the Nauill-rupture called *ομφαλοκήλη*.

From this *Peritoneum* also as from their originall doe proceede particular Coats, where-with euerie Instrument vnder the Midriffe is couered, but some of the Entrals haue thinner Coats, some thicker, according to euerie ones necessitie: as the Kidneys Coat is crasse and thicke, but those of the Stomacke, Guts, Bladder and Matrix much thicker: This Coat compasseth the proper Coat of the Entrals and is called the Common Coat; the vpper Entrals as the Liuer, the Stomacke, &c. borrow it from that part of the Rim which groweth to the Midriffe: the nether, as the Bladder and the Guts, from that part which cleaueth to the Share-Bone, as saith *Galen* in his fourth Booke *De Vſu Partium*, and twentieth Chapter. There be also two Membranes which proceed from this which are double, the Kall and the Mesenterie, and some Ligaments, as the Ligament of the Liuer. Veines and Arteries the Rim hath from the neighbor Vessels: aboue from the Vessels of the Midriffe which are called *Phrenica*; behind from the Muscles which go away by the Loynes & so run through the sides [Tab. 5. L L.] of this *Peritoneum*. Before and some-what higher [Tab. 5. K K.] from the Mammarie or Pap. Vessels which trend downward vnder the Sword-like Cartilage or Brest-Blade to the right Muscles; lower from the *Epigastricall* Vessels [Tab. 5. I. I.] ascending vnder those right Muscles it receiue certain furcles or branches for his nourishment and the preseruatiō of his naturall heat; sometime also seuerall tendrils are communicated vnto it from the Spermaticall Veines. The Nerues are very threddy which it hath from them that are distributed into the Muscles of the *Abdomen* by which it receiueh sense.

The vſes of this *Peritoneum* or Rim, are: First, saith *Galen* in the fourth Booke *De Vſu Partium*, and first Chapter, to couer the parts contained in the Lower Belly; but this vse, saith he, is not the principall, because those parts are well couered beside with the Muscles of the Paunch, a great deale of Fat and the Skin. The second vse is, that it should be a *medium* or meane betweene the Entrals and the Muscles, and so hinder the Kall and the small Guts from falling into the spaces betwixt the Muscles or vnto the Skin; (as it hapneth when this Membrane is broken) where they would cause great paine, hinder the motions of the Muscles, and the free deſposition or auoydance of the Excrements; all which inconueniencies we find when this Rim is wounded and not perfectly and rightly cured. Thirdly, it helpeth much to the speedy vnburdening of the Belly; for, because the Muscles of the Paunch and the Midriffe by reason of their different ſituation, cannot in their contraction straine the whole Belly equally & alike in euerie place: the continued position of the Rim supplyeth that want, as when a Man applyeth both his Hands vpon a Bag of Hearbs and compasseth it about on euerie side, he may more equally straine the Liquor out of all the parts of the Bag. Fourthly, saith *Galen* in the Booke next aboue named, and the ſeuenteenth Chapter,

it giueth Coats to all the Entrals of the Lower Belly, and produceth diuers Ligaments, as we haue partly touched before, and shall doe more at large hereafter. Fifthly, it firmeth and strengthneth all those Entrals, especially the Stomacke and the Guts, which otherwise being distended with wind would be violated, yea torne as it were, and their Coats sliuen afunder, beside, it tyeth them together and holdeth them fixe in their proper places. Finally, it is a saue-gard to the Vessels, which hauing a long course to run, and being but slender of themselves, are secured betwixt the duplicated Membranes of this *Peritonaeum*.

CHAP. XI.

Of the Vmbilicall or Nauell Vessels.

They are called *Vasa Vmbilicalia*, because they passe through the Nauell which is called *Vmbilicus*, for of their conuolutions or fouldings one with another, is the Nauell made; the *Greekes* call it *ὀμφαλός, ἀπὸ τοῦ ἰμπνέειν*, which signifieth to breathe, by reason of the Arteries in it by which the Infant in the Wombe breatheth or receiueth breath. *Aristotle* in the first Booke *Hist. Animal.* and thirteenth Chapter, calleth it *ῥίζα γαστρός*, the root of the Belly, because by these Vessels, as by the strings of the root, the Infant draweth nourishment from the Cake or Liuer of the Wombe, as it were out of the Earth. The *Latine* name *Vmbilicus*, is deriued *Ab Vmbone*, which signifieth the Bosse of a Buckler, which is represented in the middle of the Belly, yea in the very middle and center, (saith *Galen* 15. *De Vsu Partium* 4.) of the whole Body, if you stretch out your Armes and Legges, and draw a circle about them.

The names of the Nauell.

What it is.

The sixth Table, sheweth the Lower Belly, all the containing parts as well proper as common being remoued, and the Bowels lying in their naturall position, conuered with the Kall or Omentum, together with the Vmbilicall Vessels.

TAB. VI.

- A. That part which isyneth to the Nauell.
 B. The other that is inserted into the Liuer.

The Nauell therefore is the stumpe of the *Vmbilicall* Vessels, by which the Infant was nourished

The vmbilical vessels,

nourished in the Wombe [Tab. 6. C.] therefore implanted into the middest of the Lower Belly, because it was requisite, that as well the Alimentarie as the Vitall Blood should first apply to the parts contained in this Belly. Now the *Vmbilicall* Vessels are these: one Veine, (in bruit Beasts there are two) two Arteries sometimes, (yet that rarely) but one diuided at the inside of the Nauell into two, and in Beasts the *Vrachus*.

The Vmbilicall veine.

The *Vmbilicall* Veine [Tab. 6. from D to B.] is the first of all the Veines, yea the *Principle of Perfection* of all the parts of the Body, in respect of their fleshy Substance, because it is the Vehicle or conueigher of Blood, as well for the matter whereof all the *Parenchymata* are formed as also of all the other parts; wherefore it is also the root of the Gate-Veine, and is formed together with the *Vmbilicall* Arteries immediately of the Seed before any of the Entrals. And this truth accordeth with the opinions of *Hippocrates* and *Galen*, and with right reason: For the Infant needeth both Blood and Spirits for the generation of his parts: Now because these must be conuayed by Vessels, it followeth necessarily that those Vessels should be generated before the parts themselves; and these are they. So we see the Seed of Corne or such like, when it is cast into the Earth, first of all, shooteth out of it selfe the beginning of the Stalke and of the Root together, that afterward the Stalke may be nourished by the Root: Semblably in the figuration of Mankind at the same instant that the substance of the Body beginneth to be moulded, the *Vmbilicall* Vessell is produced whereby the Creature might be nourished and augmented.

Hippocrates. Galen.

Comparison

The passage of the Vmbilicall veine.

This Veine [Tab. 6. from D to B.] passeth through the double Membranes of the Rim, and in the Infant hauing gotten through the place of the Nauill, becommeth sometimes two, sometimes presently after his egress is diuided, so that it seemeth to be double, and together with the Arteries is compassed with a Membrane called the *Gut-let*, and so runneth out into a great length; *Vesalius* saith of a foot and a halfe long, but oftentimes it is much longer, yea sometimes that length double & treble. The Veine is full of knots, by which some superstitious Midwives gather how many Children the Mother shall haue, but their true vse is to stay and entertaine the Blood, that it might receiue a more exquisite elaboration for the nourishment of the tender Infant. The Arteries because they are ordained to conuey the Spirits for the support of life are straight and even without any bossed knots at all.

The knots of the Veine.

The manner how they nourish and sustaine the Infant.

When these Vessels come vnto the *Secundine* or After-birth they disperse through it notable branches, and lesser toward his outward part, which attaining vnto the *Liuer or Cake of the wombe*, doe forme a Net-like complication, till at length they loose themselves into small hairy strings, by which as by the Tendrils of the Roots of Plants, the Mothers Blood both Alimentary and Vitall together with the Spirit is drawne out of the Mothers Veines and Arteries into these *Vmbilicall* Vessels. From whence the Veines conuey the Blood into the Gate-Veine, and from thence by the *Anastomoses* or *Inoculations* which are betwixt the roots of the Gate and the Hollow Veines, it passeth into the Trunke of the Hollow Veine and so nourisheth the whole Body of the Infant. The *Vmbilicall* Arteries by which the Infant hath transpiration doe transport the Vitall Blood vnto the *Aorta* or great Arterie, and from thence it passeth vnto the Heart to maintaine the natieue heat and life of the little Creature. But after the Infant is borne, the Midwife after she haue stroked downe the Blood to nourish the Babe, casteth it into a Knot close to the Belly, and then cutteth it off, and the stumpe that is left is the Nauill.

A direction for Midwives

The vse of these Vessels after the birth

The way of the Dropie water.

A cruell custome of the Egyptians.

The passage of the Vmbilicall Arteries.

And because the portions of these Vessels, which are left within the Body should not be altogether vnprofitable, they are turned into Ligaments. The Veine because it proceedeth out of the Fissure or Cleft [Tab. 6. B. and Tab. 4. Lib. 3. E.] which is in the hollow part of the Liuer, and thence attaineth betwixt the two Membranes of the Rim vnto the Nauill, becommeth the Ligament of the Liuer, which sometimes in Dropie Bodyes openeth (yea and even in our dissections we haue sometimes followed it with a Probe and found it open into the Liuer) and so auoydeth by the Nauill the Water which is gathered into the Liuer: but the chiefe vse of it is to tye downe the Liuer to the Nauill that it rise not vp and so stop the descent of the Midriffe in our inspiration. And this vse of it the *Egyptians* know full well, for they vse to stay at this day their Theeues, and they liue in great torment till the Hangman or Butcher cut the Nauill, and then they dye instantly, the Liuer gathering vp vnto the Midriffe and so stopping their breath.

The *Vmbilicall* Arteries [Tab. 6. A. A. Tab. 2. Lib. 3. k. l.] arise as most doe agree (though *Vesalius* be of another mind) from the *Iliacall* Arteries, or rather they are there implanted saith *Bauhine*, and running along by the sides of the Bladder [Tab. 2. k. l. Tab. 4. Lib. 3. a. a.] they

they passe vpward through the Membranes of the *Peritonæum* vnto the Nauill, and so become the laterall Ligaments of the Bladder.

Finally, the *Prachus* [Tab. 6. b. Tab. 2. Lib. 3. i.] or the *Vrinarie* vessell in Beasts, ariseth from the bottome of the Bladder [Tab. 6. H. Tab. 2. Lib. 3. g.] and ascendeth betwene the two Arteries through the duplication of the *Peritonæum*, and issuing out at the Nauill-stead is lengthned into two Guts as it were, and maketh that Coat of the Creature which is called *Alantois*, into which the Vrine of the Calfe is poured, which is there retained till it be calued.

The *Prachus*
in Beasts.

But in Man there ariseth from the bottome of the Bladder [Tab. 6. H. Tab. 2. Lib. 3. g.] a Ligament like to the *Prachus* [Tab. 6. b. Tab. 2. Lib. 3. i. i.] but it is not at all perforated. It passeth betwixt the *Vmbilicall* [Tab. 6. a. a.] Arteries, and is firmly knit vnto the Nauell [Tab. 6. c.] to which it fastneth the Bladder, and so holdeth it suspended, that it may not moue this way or that way, or be otherwise in danger of breaking, because (saith *Varolius*) whatsoever is separated from the Blood whilst the Infant is in the Mothers Wombe, is gathered together in the Bladder. Hence it is that new-borne Babes haue their Bladders distended & full of Vrine, which they auoid in great quantity before they take any sustenance. But after-ward as the Child groweth, this Ligament degenerateth into a verie small Filament or Twist with which the Bladder is tyed to the *Peritonæum*, and so sustained, that when the Bladder is distended, his necke might not be pressed. But of these Vessels

The use of it
after the birth

we shall haue occasion to intreat hereafter more in our Discourse concerning the

Conformation of the Infant. In the meane time this shall be sufficient. And

thus much of the Common Inuesting parts of the whole Body,

and of those that are particular to the Lower Belly. Now

it remaineth that we decide such Controuerfies

as are on foot concerning them, and so

passe on to the Nutritiue

Parts.

A Dilucidation or Exposition of the Controuersies concerning the Common Inuesting Parts of the Body, and those that properly belong to the Lower Belly.

QUEST. I.

How the Haires are nourished.

THE Controuersie concerning the Haires, how they are nourished or otherwise encreased, although it be a matter of no great necessity, yet it is verie difficult and full of Philosophicall subtiltie. That they doe encrease from short to long, is not doubted: So also it is past question that nutrition goeth before accretion. *Galen* in his first Booke *De Naturalibus Facultatibus*, and in the second *De Temperamentis* saith, that their generation is like the generation of Plants; and yet in his Booke *De Arte Medicsnali*, in the ninth Chapter, where he treateth of the differences of the Members, he saith, they haue onely a generation, no gouernment; that is to say, they are generated of recrements, but not nourished or gouerned by any Naturall facultie. And in his second Booke *De Temperamentis*, he thus expresseth their production: *But if the vapor be sootie, thicke and earthy, it remaineth impacted in the strait breathing Pores of the Skin, neither easily returning backward, nor easily euacuated; wherefore another vapor succeeding from within, striketh the former and thrusteth it outward, and so one vapor following another, they are in time complicated and conioyned, and make a roping Body like the Soot in a Chimney, but are not nourished at all by the assistance of any Facultie.*

Hence it appeareth, that they are onely Excrements, and their auction is but an improper accretion, vtterly deuoid of life, and therefore they are not to be reckoned among the parts of the Body; or if they be, it is not because they doe participate of life, but because they haue other vses of couering, ornament and such like, as before in their Historie is expressed. But there are some of *Aristotles* followers, who contend that they haue a life, but that of nourishment onely, not of sense. Which distinction seemeth to me to be verie friuolous. For if you take from them any part of life, you must also take away all life. Beside the very substance of the Haire so dry and without sense, is a manifest euidence that they cannot be truly nourished. For if they assume an Aliment into themselves, and alter it for their behoofe, what should hinder that they should not encrease according to all the dimensions, length, bredth and thicknesse? But we see manifestly, that they onely encrease in length and not otherwise, receiuing their Additament or Aliment, whether you will call it, onely at their Roots, not as other parts equally on euerie side. It will be objected that the Nails and the Teeth doe also receiue their Aliment after the same manner, and yet they are liuing parts. We answer, there is great difference. For the Nails and the Teeth haue all kinds of Vessels, Veines, Arteries and Nerues, inserted into their Roots, by which they receiue

Obiection.

Answer

receiue nourishment and sence, so haue not the Haires; and the reason why they are onely nourished at their Roots, is because Nature foresaw, that by continuall attrition & collision they would soone be worne away, vnlesse new matter were supplied vnto them at their Roots; and truly we willingly confesse, that the extreme parts of the Nails and Teeth which are farthest from their Roots doe not liue, neither are nourished properly, but onely are driuen forward by apposition and impulsion like as the Haires are. But it should seeme that the nature of the Haires and of the Nails is all one, because they both encrease in dead Carcases. Wherefore if the Nails be nourished, why should it be denied that the Haires also doe grow by nourishment? Hereto we answer, that true it is, as well the Nails as the Haires doe shoot out after death, but the manner is not alike; for the Haires, so and from the same causes grow in length after death, as they did before; the heat of corruption and putrifaction seruing as well, so long as the matter lasteth, to driue out the Excrement after death, as the naturall heat did while the Man was alieue; but the Nails doe not grow as they did in the life time, but onely become more prominent, the adiacent parts sinking from them, as being consumed by putrifaction. But it may further be vrged, that the nature of a putrified excrement when it is not ouer-ruled by the facultie, is not to breath outward to the Circumference, but to gather inward vnto the place where the most putrified matter is; and this is daily obserued euen in liuing bodies, that till the offending humor be brought into subiection vnto Nature, and receiue a kind of mitigation, it gathereth still to the Center; afterward, Nature hauing gotten the victorie, she driueth it as farre from her as is possible, euen to the Skin; as we see it falleth out in Criticall Sweats, in the Meazels, Small Pockes, and such like. Now if the putred Excrement haue no disposition to the Circumference in liuing Bodies when the secret passages of the Body are open, the Skin Porous, and the Faculties euery where at worke; how shall it passe that way after those passages and Pores are false, the habit forsaken of the Spirit, and the transpirable wayes locked vnder the Seale of Death? It seemeth therefore more reasonable to thinke that the matter of the Haires which is added after death, was a surplusage of the last concoction celebrated in the habit of the Body, and remaining in the extremities of the Vessels which determine in the Skin, which being in that place intercepted by the extinction of naturall heat, and hauing no Spirits to guid it backward; yet hauing before attained the perfection which the Facultie could impart vnto it, worketh it selfe a way through the Skin. But this knot will easily be vntied, if we consider that after death the Haires do not grow or encrease in any place of the Body, but onely in such, as wherein there were Haires standing in the time of life, to the Roots whereof, as I said before, the heat proceeding from putrifaction, is sufficient to driue, though not any humor, yet a vapor which may passe where the way was before thrilled and bored, but cannot where the Skin was not notably perforated. Again, there is a double limit, beyond which the excrecence of the Haire doth not proceed. For if either the confluence of the vapor to those Pores make a dampe, as in proesse of time it will, or the putrifaction of the vapor grow to a Venom, then the Haires cease to encrease, but fall not so soone in dead Carcasses as in liuing Men, because the Aire exiccateth and dryeth the Skin wherein the Roots are fastned; but in those that are alieue whose Skin is open, they fall not vpon a dampe, for there can be no such thing in a liuing Body, but vpon a confluence of a venemous vapor, as we see in the *French Disease* and the *Leprosie*. And so much of the Haires.

Obiection.
That Haires

QUEST. II.

Whether the Skin be the Organ or Instrument of Touching.

THE Philosophers and Physitians strue about the Instrument of Touching. *Aristotle* and *Alexander* call Flesh somtimes the *Medium* or meane through which we feele, sometimes the Organ or Instrument of feeling it selfe, but neuer the Skin. First, because the Skin is of it selfe insensible, and sensible onely by reason of the Flesh. For the Skin of the Head which is without Flesh, say they, is insensible. Secondly, because Flesh bared or exposed to the Aire, is more painfull then the Skin. Thirdly, because there is a more exquisite and discerning sence in the Flesh then in the Skin. For that Iewellers and Lapidaries doe more accurately discern the differences of roughnesse and smoothnesse,

The
Peripaterians
arguments.

An Axiome.

and such touchable qualities by the Tongue then by the Hand; and are able to distinguish betweene naturall and fictitious Precious Stones onely by the touch of the Tongue. Lastly, because it is a rule in Philosophy, that the sensible subiect being placed immediately vpon the Instrument of Sense is not sensible, but such sensible subiects placed immediately vpon the Skin are felt, therefore the Skin is not the Instrument of Touching.

sion.

Answer
to *Auicenna*.

To these may be added the authoritie of *Auicenna*, who writeth, that the Skin feeleth not equall Bodyes or Obiects; if it feeleth not equall Obiects, then it is not the proper Organ or Instrument of Touching; because euerie Instrument of Sense which the *Grecians* call *αἰσθητήριον*, apprehendeth both extreme and also middle Obiects; so the Eye seeth both the extreme colors which are blacke and white, and also all middle colors made of their mixture, whether they containe lesse or more of either of the extremes. On the other side, the Physicians affirme the Skin to be the Instrument of Touching, which will appeare to be the more probable and likely opinion whether we consider the Temper, the Structure, or the Scituation of the Skin. For the Temper, the Skin is the most temperate of all the parts and in the very midst of the extremes, and is as it were the Canon or rule of them all; and therefore can giue a more perfect iudgement of the tactile qualities.

Aristotle hath determined that euerie *αἰσθητήριον* or Instrument of Sense should be *ἀσθητόν*, that is, deuoid of all qualities whereby that sense is affected. So the Christaline humour which receiueth the Images and specres of visible things, is deuoid of all colours; the yellow Eyes of those that are full of the Jaundise imagine all things to be yellow. If the Tongue be moistned with choller, all things though sweet haue a bitter range: In the Nose there is no particular and peculiar sent; no sound naturally residing in the Eare: Right so the Skin which hath no excessse of qualities is to be esteemed the Organ or Instrument of Touching.

If we consider the Structure of the Skin, there are moe Nerves disseminated into it then into the Flesh, but the Nerves are the common conueyers of all sensible Spirits, which they continually minister vnto the Senses, whereby their operations are perpetuated. And for the scituation of the Skin, it is much more commodious then that of the Flesh, because it is neerer to the occurration or confluence of outward obiects; because it is the limit and border as it were of all the parts. The Skin therefore is rather the Instrument or Organ of Touching then the Flesh. As for the fore-named obiections of the *Peripatetiks* they are easily answered: For first, we deny that the Skin feeleth by helpe of the Flesh. I instance thus: Cut a Nerue which endeth into the Flesh, presently the motion will cease, but the sense of the Skin will remaine; but if a Nerue be cut which passeth vnto the Skin, presently the sense it selfe will be abolished. Againe, true it is that Flesh when it is bared is more sensible and painfull then the Skin; but the reason of that is, because it is looser and lesse accustomed to outward iniuries of the Aire or ought else; whereas the Skin is so accustomed to the Aire, that it feeleth it not. So the Teeth being vsually opposed to the Aire, are not affected therewith; but other Bones if they be bared doe presently putrifie. To proceed, the Tongue hath a more exquisite apprehension of the coldnesse and inequality of Precious Stones; but that apprehension is not from his Flesh but from his Membrane; now Membranes are also Instruments of Sense. And whereas it is said that the sensible subiect or obiect being placed immediately vpon the Instrument of Sense, is not sensible; that I say is vtterly false, for by that reason there should be no Organ of Touching saue onely a Bone, a Gristle, or a *Vinculum* or Tye.

That Axiome of *Aristotle* stands need to be interpreted: Of the Senses some are absolutely and simply necessarie to our life, as Touching and Tasting; some are *ad bene esse*, that is, for the better being of the Creature, but not simply necessarie to his being, as Sight, Hearing, and Smelling. The *Medium* or meane of these last is externall & separated from the Instrument; the *Medium* of the first is internall, and so ioyned with the Instrument that it cannot be separated. In the first this Axiome is true; for if any colour be layd vpon our Eye, we see indeed, but very depraudedly, being not able without an outward meane to distinguish, so likewise it is in Hearing and Smelling: but in Tasting and Touching because the *Medium* is internall, the obiect may be, yea is best distinguished when it toucheth the Instrument. We therefore conclude, that the Skin is the Organ or Instrument of Touching, and the Cuticle or Scarfe-Skin is his *Medium* or meane.

Whereas *Auicenna* saith, that the Skin doth not feele equall or temperate things, he meaneth that it is not violated or ill affected by them when it feeleth them, not that it feeleth them

them not at all: for that common experience would condemne. Lastly, you will say that the Skin feeleth by the helpe of Nerues; the Nerues therefore are the Instruments of feeling, not the Skin. I answer, the Flesh of the Muscles are moued by the Nerues, yet is not the Nerue the immediate Organ of voluntarie motion, but the Muscle. In like manner the Nerue giueth sense vnto the Skin, because it bringeth downe vnto it the Animall facultie and Spirit, yet nathe-more is it the immediate Instrument of Sense. But *Galen* saith, that the Stomacke is the Organ of Touching, because his sense is most exquisite: Surely the Mouth of the Stomacke is wondrous sensible, because of the notable Nerues it receiueth from the sixth coniugation, and by reason of the hunger and thirst of which it onely is apprehensue: we acknowledge it the Instrument or Organ of a peculiar & particular Touch, as also the parts of Generation haue their peculiar Touch whereof they are Instruments; but onely the Skin is the Organ of externall touching, and sole Iudge of all tactile qualities.

Peculiar
touches in
mens bodies.

QUEST. III.

Of the Temper of the Skin.

Alen is of opinion that the Skin is absolutely temperate, because it is of a middle nature betweene bloody and vnbloody, whence it is called a Neruous Flesh and a Flethy Nerue; so in another place, if the Flesh be adstringed and dryed, it becommeth like the Skin; for the Skin is dryer and thighter then the Flesh.

That the Skin
is temperate.

Hippocrates also expresseth so much, where he saith, *The outward Skin which is continuall with it selfe and with the bloody Nerue, because it is exposed to the Aire, sometimes colder, sometimes warmer, is often affected by both, and needs now and then the helpe of the one to temper the other.*

Hippocrates.
That it is not.

On the contrarie it may be proued by the authorities of *Galen* & *Auicenn* that it is not Temperate. *Galen* saith, that the Skin is nourished with Phlegmaticke Blood; it is therefore of the Temper of Phlegme, for the nourishment of any part is the same with that whereof it is compounded. *Auicenn* saith, that the Flesh commeth neerer to exact equalitie of Temper then any other part. The Flesh therefore and not the Skin is Temperate. Moreouer, that cannot be temperate which is the weakest of all parts: Now the Skin receiueth the superfluities of all the inward parts, and is therefore called the Vniuersall Emunctorie. But all these Knots may easily be cleft with a soft Wedge. The Skin is nourished with Phlegmaticke Blood, that is, not fully boyled and laboured, when we know it is hot not cold. *Auicenn* saith not, that Flesh is most temperate, but that it commeth neereft to that which is temperate; so the whole Body of Man is said to be temperate, although it be hot and moyft.

Galen:

Answer
to the argu-
ments which
proue it to be
temperate.

The weakenesse of the Skin proceedeth not from the Temper, for it is not weake of it selfe, or of it owne nature, but by euent, by reason of the scituation and the Vessels. For the greater Vessels because they are neerer to the Fountaine are the stronger, and the expelling vertue of the inner-parts more powerfull: Whence it is, that the inward parts expell their superfluities into the outward, and the greater vessels into the smaller vessels of the habit; so that the Skin becommeth weaker, because the expelling faculty is withinward & stronger, and layeth all the burden vpon the Skin. And so much for satisfaction of the Aduersaries.

Why the Skin
is weake and
becomes an
Emunctorie.

There is another scruple arising out of this Doctrine of the Temper of the Skin; and that is, whether a Physitian by the Skin may iudge what is the Temper of the whole Body. *Aristotle* gathereth from this Instrument of Touching, the vigour of the mind it selfe, because where the Touch is fine, there the Sense is lesse polluted, and the Phantasmes arising therefrom more subtle; and so the operation of the Soule higher and more abstruse. *Galen* resolue the doubt, where he saith: They are in an error who doe determine alwaies of the Temper of the whole Body by the Skin; for though the Skin be hard, yet is not the Creature necessarily dry; neither if it be soft and without Haire is the whole Creature moyft; yet if the whole Body be in equall Temper, then it is reasonable that all the parts should be proportionably correspondent to the Temper of the Skin, but if the Body be vnequally tempered as often-times it is, from the Nature, by accident, or by disease, then is it not reasonable to iudge of the Body by the Skin. For we see that in Oysters the Flesh is very moyft, yet is their Skin, which is their Skell, beyond measure dry.

Whether by
the Skin the
temper of the
whole body
may be
knowne.

QUEST. IIII.

Of the Originall and Generation of the Skin.

The common
opinion.

Other opini-
ons.

The difference
betweene a
scar and the
true skin.
Another opi-
nion.
But proued
false.

The determi-
nation.

An argument
that the skin
is made of
seede, and
blood.

Here are many opinions about the generation of the Skin. The common opinion is, that it ariseth from the dilated ends of the Veines, Arteries and Sinews, because it euery-where feeleth, liueth and is nourished: Now life is communicated by the Arteries, nourishment by the Veines, and sense by the Nerues or Sinews. For my owne part I doe not deny but that many Vessels are carried vnto and doe determine in the Skin from the Axillarie, Iugular & Crurall Veines, many small Surcles, and as many Arteries bearing them company: Interlaced also it is with manifold Nerues, but yet I am not resolu'd that the Skin is wouen together of their Threds. *Galen* thought the Skin was the first part of the Infant that was formed, the truth of which assertion we shall diseusse in another place. Some thinke the Skin is made of the superficies of Flesh dried, because in wounds the Flesh dried degenerateth into a Cicatrice or scar, which is very like the nature of the Skin; this may be confirmed by the authorities of *Aristotle* and *Galen*. *Aristotle* auoucheth that as the Flesh groweth old, so it turneth into Skin. *Galen*, that the Skin is produced out of the Flesh which is vnder it. But because between the Flesh and the Skin there are many Bodies interposed, to wit, the Fat and the Flethy Membrane, which is truly Neruous, vnlesse it be about the Necke and the Face; I cannot see how the Skin should grow out of the Flesh. And that Skin or Scar rather which resulteth vpon the wounds, when the Flesh is softned and dried by *Epulotical* Medicines as they call them; is not a true Skin but illegitimate, ingendred of a substance of another kind; for it is harder then the true Skin & more thight, and therefore neuer hath any Haire growing vpon it; and in tanning it will fall away, whence comes the holes in Sheep-Skins when they are made into Parchment. Some thinke it is compounded of Flesh and Sinews mingled together, because in many places of *Galen* the Skin is called a Bloody Nerue; but this is proued to be false by this one argument, because where there is most store of Nerues, there the Skin is not the harder for them; as in the Palme of the Hand there are more Nerues then in the Crowne of the Head, & yet the Skin in the Crowne is much harder then that of the Palme. I thinke, and for this time determine, that the Skin is ingendred together with the other parts, to wit, of Seed and Blood mixed together; and may therefore be called a Flethy Nerue, or a Neruous Flesh, because it hath a middle nature betweene Flesh and a Sinew: For it is not vtterly without Blood as a Nerue, nor so abounding with Blood as Flesh. That there is Blood in it appeareth euidently if it be neuer so little wounded: That it is of Seed, this one argument may serue for all, that when it is perished it can neuer be restored; for it is impossible to heale a wound where any part of the Skin is taken away without a Scar or Cicatrice more or lesse.

QUEST. V.

Whether the Skin performe any common and officiall Action.

The common
opinion.

*Hip. lib. de natu-
ra. of sinum.*

The common
action of the
skin is animal.

How sensation
is made.

MAny Physitians haue the same opinion of the vse and action of the Skin which they haue of the vse and action of Bones. The Bones haue a common or officiall vse, so saith *Hippocrates*, they giue the Body stabilitie, vprightnesse and figure, but they performe no common or officiall action. I account that a common action which is seruiceable either to more parts or to the whole Creature. In like manner, the Skin hath indeed a common vse, because it couereth the whole Body, cherisheth it and tyeth it together, but it is not thought to performe any officiall or common action. *Galen* speaketh very plainly, *The Skin* (saith he) *concocteth not, as the Stomacke; it distributeth not, as the Guts and the Veines; it breedeth not Blood, as the Liuer; it frameth not any pulsation, as the Heart and the Arteries; it causeth not respiration, as the Lungs and the Chest; it moueth not with voluntarie motion, as the Muscles.* Notwithstanding all this, one common action may be attributed vnto it, to wit, an Animall action. For although all sensation is passion, because to be sensatiue is to suffer, yet there is no sensation without an action. The better learned Philosophers in all sensation doe acknowledge a double motion, one Materiall, another Formall: The former motion

motion is in the reception of the Species (for we must craue libertie to vse our Schoole rearmes) the latter in an action; the first is in the Instrument by reason of the matter, the latter by reason of the power is in the Soule; the first is not the effectuating cause of sensation, but a disposition thereto; the latter is essentially sensation it selfe. Whereas therefore the Skin is apprehensive of those qualities which strike or moue the tactiue sense, and is thereupon esteemed the Iudge and discernet of outward touching, it performeth vnto the whole Creature not onely a common vse, but also a common or officiall action. Beside it hath another priuate action, to wit, Nutrition, to which as Hand-maids doe serue the Drawing, Retaining, Concocting and Expelling Faculties, and more then these hath no part in the Body of Man which serueth for the behoofe of the whole. We conclude therefore, that the Skin beside his common vse and priuate action performeth to the Body a common and officiall action, to wit, Sensation.

The priuate
action of
the Skin.

QUEST. VI.

Whether it be heat or cold, whereby Fat is congealed.

THE diuers, yea contrarie gusts of opinions amongst ancient Physitians about the generation of Fat, hath rayseed such a tempest in our Art, that the waues are not to this day settled. There needeth therefore some *Aolus, mulcere hos fluctus* to appease these waues, to call in the winds, or to abate them into a calme, which we will at this time intend to doe in want of better helpe as well as we may. And because we would not be accumbred with the varietie of names which are vsually giuen to this substance, you shall vnderstand, that *Pinguedo, Adeps, Auxungia* and *Serum*, are promiscuously vsed by Physitians, albeit *Aristotle* and *Galen* haue taken great paines to distinguish them euerie one from another. To which places, we referre those who desire herein satisfaction. For we will onely paine our selues about the temper and generation of Fat at this time.

The names
of Fat.

2. *De Part. Animal.*
4. *et 11. De Simpt. Medic. Facultat.*

Galen is of opinion, that Fat is congealed by cold, and that he expressly declareth together with the manner of it in this manner. When the airy & more oily part of the Blood sweateth through the thin coats of the Veines in manner of a dew, and lighteth vpon the colder parts such as are Membranes, it is then by the power of the cold condensed. And hence it is, that Women are for the most part fatter then Men, because they are colder; and the same reason is of all other Creatures growing fatter in the Winter time, as doe also those that haue smaller Vessels; now we know, that the smalnesse or narrownesse of the Vessels, is caused by the coldnesse of the Temper. And if at any time those Creatures which haue large Vessels doe yet grow fat, it is not from their naturall, but from an aduentitious temper acquired by accident (to wit) by dyet and order of life. Moreouer, that Fat is congealed by cold, hence it is euident, because by heat it is presently molten and liquefied. The lower Belly because it is Membranous & farre remoued from the Fountaine of Heat, is therefore couered ouer with a leafe of Fat, which somtimes is of great weight; but the parts vnder the Brest haue lesse Fat about them. And this is the Philosophy of *Galen*, and almost all the *Greeke* and *Arabian* Physitians. Those that hold the contrarie, doe thus demonstrate the matter of Fat to be hot, the worker of it Heat, and the effects of it hot. For the matter, *Galen* himselfe acknowledgeth it to be made of the airy and oily part of the Blood, as also is *Choler* and *Seed*; and therefore those Creatures that are fat grow barren, and if we would fatten any thing, we first lib or geld it. And *Aristotle* saith, that that which is fat, is neither earthy nor watry, but airy, and therefore it floteth alwayes aboue. Now Aire we know is hot and moyst. That the efficient or working cause is hot, *Aristotle* first of all Men proued, where he saith, That Fat is made by concoction or boyling, but it is onely Heat which concocteth or boyleth any thing. And in his *Problemes* he giueth this reason, why that which is fat is not of ill sauer, Because (saith he) it is not crude or raw, but concocted. This opinion of the Philosopher doth the learned *Veiga* follow and *Argenterius*, as also *Laurentius Ioubert*, who set forth an elegant and subtile Paradoxe concerning the nature of Fat. The weight of the principall reasons for this opinion, we will as briefly as we can set before you. All concretion is made by that which is actually cold, as is seene in Ice, Oyle, Hony and such like, which by the outward cold Aire is congealed: but there is no such actuall cold in a liuing Body; the Bones are very hot if they be touched, and all the Mem-

branes are actually hot, for the membranous Stomacke boyles the *Chylus*, the membranous Bladder burneth the Flegme euen into a Stone. *Auicenn* saith, that the Membranes are hotter then the Braine; now the Braine is hotter then the most foultry hot Aire that is in the heat of Summer: but the Summer heat melteth and congealeth not; the coldnesse therefore of the Membranes cannot congeale the Fat. Againe, the Heart which is the hottest of all the inward parts, and in perpetuall motion, is yet compassed about the *Basis* with abundant Fat. About the Membranes of the Braine, which are watred as it were with abundance of Blood, and wouen with many thousand Vessels, neuer any Fat adhereth: nor vnto the coats of the Bones. Old men and Melancholy persons, whose temper is cold, haue yet little Fat. The Kidneyes which are very hot, and bake, yea burne Flegme into Stones, haue yet about them abundance of Fat. Beside, the Fat is a liuing part of the Body, because it hath a certaine and definite forme or figure, and is whitened by the power of the Membrane which altereth it; now who euer durst say, that a liuing part of Mans Body was made by a ctuall cold? We may also adde the authoritie of *Galen* fauouring their opinion, where he saith, That in cold and dry Bodyes the Fat is larded amidst the Flesh, not about the membranous Coats; but euerie one will confesse that Flesh is hot. Finally, the effects doe teach vs that Fat is hot. For *Galen* reckoneth it among concocting Simples; and the fatty Kall (saith he in his Booke of the vse of Parts) by his heat furthereth the concoction of the Stomacke; beside, it easily taketh fire. Wherefore they referre the cause of the concretion or congealing with *Aristotle*, to the fastnesse and thightnesse of the Membranes. For say they, the airy and fat part of the Blood, passeth easily thorough the rare and spongy Flesh: but when it commeth to the Membranes, there it is stayed and congealed by heat, and becommeth white through the operation of the Spermatieall part to which it adhereth, to wit, the Membrane. Adde hereto the authoritie of *Hippocrates*, who saith, *That heat is the seat and residence of Fat.*

Thus you see the Battell pitcht on either side, and contrarie Ensignes and Armes in the Field. Both parts cannot be maintained. It is more safe to side with the old Legions led by *Galen*, and followed by the Ancients, then with new and vp-start Nouices: wherefore, we will determine thus; I wish it may be with approbation of the best.

The matter of Fat is airy and oily, the efficient cause a congealing cold, yet not absolute and actuall (for there is no such cold in any liuing Creature) but lesse hot, which Philosophers take for cold, so that the Fat is congealed not by parts that are absolutely cold, but by parts that are lesse hot then others, such as are Membranes. But this may better be exemplified, then taught by precept. Lead, as soone as it is taken off the Fire, although it be yet fiery hot, caketh together: this concretion is either by vertue of heat or cold; not by a fiery heat, for that melted it before; not by actuall cold, for if you touch it thus caked, it will burne; therefore by a remisse heat, which to it is in stead of cold. For there is a certaine degree of heat, which will not suffer Lead to cake, nor Fat to curdle. This degree is onely in the Fleahy parts; whence it is that Fat neuer growes about them. But Membranous parts, because they haue not the same degree of heat, doe curdle the oily part of the Blood into Fat. When a Vessell of boyling Water is couered, though the couer be hot, yet the vapor of the Water turneth into a steame vpon it, and will stand in drops, yea will run from it in Water, as we see in Stils, though the Head be so hot that a Man cannot touch it. What then is the reason? Because in the couer there is a lesse heat then in the boyling Water. For it is heated onely by a vapor, the Water immediately by the Fire. The lesse heat therefore of the Couer or Head, is in stead of cold to the boyling Water.

In like manner, in Melancholy Men their hot and boyling Entrals raise vapors, which when they come to the Skin which is lesse hot then the Entrals, are gathered and thickned into Sweat. So the breathing vapors of all the lower parts being raised into a hot Braine which yet is lesse hot then the lower parts, are turned into Water, and fall downe in Rheumes, Gowts, and such like. After this manner therefore we say that Fat curdles by cold, that is, by a lesser heat then will melt it; so we say the Braine is cold, that is, lesse hot, although it be hotter (as we haue said) then the Aire can be in the heat of Summer. That Summer Aire or hot Gleames we call hot, and so they are; yet are they cold in respect of Fire, yea cold in respect of the heat of a liuing Creature; the Heart by them being refrigerated: For our life is proportionable to Fire; and it is a true rule in Metaphysicks (that is in Logicke) that *Meanes are contrarie to their Extremes*, else should not Liberalitie which is a Vertue, be contrarie to Couetousnesse & Prodigalitie, which are the Extremes and Vices.

These

These things being thus first determined, we will now answer the Arguments vrged against vs. First, we deny that all concretion or coagulation is done by actuall cold; for as it is said, Lead yet fiery hot will congeale; and whereas Fat groweth to the Heart, which is the hottest of all the parts, we answer, that herein is a great document of the wonderfull and prouident wisdome of Nature, who hath thus prouided least in perpetuall motion the Heart should gather so great a heat as should waste and consume it; for which cause also saith *Hippocrates*, it lyeth in water much like Vrine, that it might euer be fresh, and as it were flourishing.

Answer to the former arguments.

The wonderfull prouidence of Nature.

Chrysippus that notable *Stoicke* in his Booke of *Prouidence*, saith that the finall cause ouercommeth both the efficient and matter in naturall things; and *Aristotle* against *Democritus* saith, that in the workes of Nature the end is the first and chiefe cause, for it moueth the other causes, it selfe being immouable. I know that our aduersaries will object, that Nature induoureth nothing against her owne Lawes, she should therefore haue made the Heart temperate. But let me retort their owne weapon against them, Nature should haue made the Heart originally temperate, that there might haue been no need of breathing cold aire; how absurd this opposition against the wisdome of Nature is, no Man but seeth. For the Heart was necessarily to be created very hot, because in it is the Hearth and Fire whereby the naturall heat of all the parts is preserued and refreshed. If they thinke not the Fat of the Heart necessarie, let them remember that it groweth not in the Ventracles, nor in the Flesh of the Heart, but onely vpon the Membranes of the Vessels, which are parts lesse hot then any of the other. Some there are which adde further that this Fat is a part of the Heart, because it keepeth alwayes the same figure and circumscription, and is not melted by Fire, but rather torrifieth.

The finall cause is the first and chiefe in workes of Nature.

For the Membranes of the Braine, we say they haue no Fat, because there was no vse of it; yea it would haue hindred the breathing out of the smoaky vapors by his clamminesse. For the Braine like a Cupping-glasse draweth continually and sucketh vp the expirations of the inferiour parts, to which if the Combe-like Sutures of the Skull did not gape and giue way, the Braine would be made as it were drunke with their abundant moystures. Beside, Fat would haue hindred the motion of the Braine, for it moueth perpetually as the Pulse doth, as we shall shew in due place; wherefore in the Braine there wanteth the finall cause of Fat. The materiall cause is also wanting, because there is required a great abundance of Blood for the nourishment of the Braine, and for the generation of Animall Spirits; it behoued not therefore that it should be conuerted into Fat. Old men and those that are melancholy are seldome fat, because the materiall cause of it is wanting, for they are too dry. The Fat of the Kidneyes compasseth not the Flesh, but their Membranes onely. *Aristotle* saith, that both Kidneyes are fat, but the right lesse then the left, because it is the hotter. And whether the Fat be a living part, we shall dispute in our next exercise. Finally, whereas *Galen* saith, that in cold and dry Bodyes the Fat is larded through the Flesh, not through the Coats or Membranes. We answer, that by Flesh in that place he vnderstandeth the Muscles which are couered with their proper Coats, to which Coats the Fat groweth, because they abound with Blood and Veines; but in those Coats that are most distant, whereof he there speaketh, because of their drynesse there wanteth matter of Fat; for you may remember we taught you before, that Fat is not ingendred but onely where there is an ouerplus of Blood which sweateth through the spongy Flesh after it is satisfied. Now in cold and dry Bodyes, such as *Galen* there speaketh of, there is no such abundance of Blood that there should be any ouerplus. The effects of Fat which they mention, conclude nothing; it is true that Fat is a concocting Medicine, and that the Fat of the Kall relieueth the heat of the Stomacke, but not primarily and of it selfe, but by euent, because the thicknesse and visciditie or clamminesse of it hindreth the euaporation of the heat, which by that meanes is doubled; besides, it stoppeth vp the Pores, that the piercing cold cannot reach vnto it. Wherefore it heateth the Stomack, as Cloathes heat the Body, not by adding heat, but by keeping the naturall heat in, and externall cold out. That it easily flameth, proceedeth from his oily and airy matter, so Camphire burneth in the Fire, which yet all Men take to be cold.

Why there is no Fat in or about the Braine.

Why Melancholy men are leane.

Galen expounded.

How Fat heateth the Stomacke.

Why Fat flames.

Moreouer, the effects doe not proue the efficient cause of Fat to be heat; for Oyle which becomes thicke and congealed in Winter, presently taketh flame, and yet no Man will deny but that it is congealed by the externall cold of the Aire. We therefore conclude that Fat is curdled by cold, that is, by a lower or more remisse degree of heat, & that it

The conclusion.

it groweth or adheareth onely to Membranes, because their heate is weaker, as hauing no continuitie with the Heart, and therefore deprivied of that plentiful influence of heat there-from, which the other parts of the Body doe enioy which haue a more notable continuitie with it.

QUEST. VII.

Whether Fat be a living and animated part of the Body.

Authorities
to proue the
Fat to be a
living part.

HEY who imagine that Fat is curdled or congealed by heat, beare themselves much vpon this Argument, that no true part of the Body is condensed by cold: Now say they, Fat is a part and a living part of the living Creature: This point we call into question. It may, I confesse, be made probable both by authorities and by arguments. *Galen* in his Commentaries, reckons it among the Similar parts; and in another place he saith, it euerywhere performeth the same office as the Veines, Arteries and Sinewes; if it performe any office to the Body, then certainly it is a living part. Againe, in another place where he reckoneth vp foure differences of parts, he reckoneth the Fat among those that are gouerned by themselves. In his Booke of the *Differencies of Diseases*, he saith the number of the parts is abated, if the Arteries, the Veines, the Nerves, the Flesh and the Fat, be not accounted among them. In his Booke of the *Vnequall Tempers*, the parts of the Fingers and Toes are these; the Bones, the Cartilages, the Ligaments, the Arteries, the Veines, the Flesh, the Skin, the Fat. And the Authorities may be seconded by Arguments.

Galen

Answer
to the au-
thoritie.

Why Haire
and Fat grow
not in old age

How the Fat
becomes
whitish

For the vntying of this Knot, we must know that there is a two-fold acceptance of a part, one more large, the other more strict. In the large account, whatsoever addeth any thing to the accomplishment of the whole, may be called a part of the whole which it helpeth to accomplish. In which respect the Fat deserueth the name of a part, as also the Haires, the Naitles, the Marrow, the Blood, yea and Milke it selfe. But in the more presse and strict signification, the Fat cannot be called a part, because it neither partaketh of a common life, as we say, neither hath it any proper figure or circumscription. And moreouer as *Galen* witnesseth, in Famine and want of Nourishment it may be conuerted into Nourishment: now one part cannot nourish another, but all parts that inioy common life, haue also one common nourishment, either immediate or mediate. Adde to this, that it is neither a Spermaticall nor Fleishy part; not Spermaticall, because it appeareth not in the first delineation of the parts; not Fleishy, because all fleshy or bloody parts are red: and therefore it is no living part partaking of the living Soule.

Concerning the places alleaged out of *Galen*, where he calleth it a Similar part, he vseth the name of part in the larger signification; where he saith, it is the author of a function, or performeth an office: by office or function he meaneth a vse. For *Galen* often confoundeth an action and a vse, although there is great difference betweene them; for the Haires haue a vse, yet they performe no office or action. Whereas they obiekt that it is increased; we grant it, but how? By apposition onely, as the Haires also grow and increase, not by assimilation of Aliment as other parts doe: and therefore it onely increaseth so long as it hath matter, when the matter ceaseth, as in old age it doth, then it ceaseth to be generated.

The whitenesse of the Fat say some, is acquired not by the forming facultie, but by cold, as all Phlegme is white, whose efficient cause is cold. I thinke the whitenesse comes by a light alteration which the Blood hath from the Membranous parts. For when as any notable quantitie of Blood falleth vpon the Membranes, it receiueth indeed a light rudiment of alteration from the power or facultie of the Membrane; but because the quantitie is greater then can be assimilated, and yet it is impacted about the Membranes, it is condensed by their weake heat; but is not changed into the nature of the part where it is condensed: so that if it be a part, it is but an imperfect part; and this *Aristotle* perspicuously discerned

discerned in his Booke of Parts, where he saith, that there is this difference betweene Flesh and Fat: That in the generation of Flesh the Blood is so thoroughly laboured and mitigated that it is turned into a part partaking of Sense: but in the generation of the Fat, the Blood is indeed changed into a part, but that part is not capable of Sense.

The last Argument may thus be answered: The Kernels which are found among the Fat, are not generated by the Fat, but haue a delineation, though not conspicuous in the first forming of the parts, and afterward the Fat incompasseth them or groweth about them: or it may be said, that those Kernels are generated by the heat of the adiacent parts, not of the Fat. And these are the Questions which are controuerted concerning the Skin and the Fat.

QUEST. VIII.

Of the Membranes, vse and production of the Peritonæum.

Concerning the Rim of the Belly, there is some difference betweene the Ancients and the later Writers, yea and amongst the *Neotericks* themselves. The Ancients thought it was a single and simple Membrane, because in Dissection it appeareth to be very fine and thin like a Cobweb. *Columbus* saith, that it is single onely from the Brest-blade to the Nauill, and double from thence to the Share, and that because of the Vmbilicall Vessels which are carryed through the Duplication. *Laurentius* saith, he hath alwayes obserued it double euery-where; aboue and below, before and behind, on the right-hand and on the left; and auoucheth that all Membranes of the Body, euen the *Pia Mater* or thin Membrane of the Brane, are alwaies double. For, saith he, as below betweene the duplication of the *Peritonæum*, there arise two Arteries and the *Ourachos* vnto the Nauill, so from the Nauill to the Liuer passeth the Vmbilicall Veine betweene the same duplication aboue; and therefore wondreth at *Columbus*, who was so occulate an Anatomist, and yet did not obserue so much. *Galen* obserued a third vse of the *Peritonæum*, which is to presse the Guts, and to driue downe the Excrements of the Belly. This vse *Vesalius* derideth: for how can it haue this vse (saith he) when it hath no voluntarie motion of his owne, whereby it can contract and distend it selfe? By the same reason, the *Pleura* should helpe the Midriffe in the contraction of the Chest. We answer for *Galen*, that he doth not intend that the *Peritonæum* doth this by his owne proper motion, or by it selfe, but onely by accident and euent. As when the Muscles of the *Abdomen* and the Midriffe like Hands ioyned aboue, and open below, doe presse and driue downe-ward that which is straightned in the midst betweene them, then the *Peritonæum* which holdeth these two in their proper positions, maketh the pressure more forcible.

Vesalius beside denies, that there are many productions of the *Peritonæum* in Women, because their Testicles doe not hang downe, but are trussed vp to the sides of the Wombe; but he obserued not that these productions reach in Women to the Leske, and become the *Cremasteres* of the Wombe, and that there are the same holes or passages in the Tendons of their oblique descendend Muscles which are in Men; whence it commeth to passe, that Women are often troubled with the *Bonbonocle*.

Columbus.

Laurentius.

All the Membranes of the body are double.

Galen's 3. vse of the *Peritonæum* derided by *Vesalius*.

Galen expounded.

Why women are so often troubled with *Bonbonocle*.

QUEST. IX.

Of a new kind of Compunction of Dropsie Bodyes through the Nauill.

It shall not be amisse in this place, to annex a kind of Compunction of the Nauill, by which the Water is safely let out in Dropsie Bodyes. The ancient Physitians called all Apertions of Dropsie Bodies *παράκρυσις*. In the administration of which *Paracentesis*, there arise foure Questions. Whether it be feasible, when, where and how it is to be performed. That it may be done safely, remaineth vnder the Testimony of many Witnesses, all beyond exception; and beside, it may by reason be demonstrated. *Hippocrates* first of all other, prescribes it both in his Aphorismes, and also in diuers other places. *Galen* in the 14 of his Method, *Paulus* of *Aegina*, *Albucaſis*, and in a word, almost all Physitians.

Paracentesis.

That it is feasible.

Hippocrates *Galen.*

Besides

Besides Authorities, Reason also addeth her suffrage to this attempt. For when these restagning or gathering Waters, can neither by outward nor inward Medicines be euacuated, why should we not proceed to Section in these, as well as in other watery and flegmaticke Tumors? Especially seeing the parts wherein the Section is to be made, are all ignoble and base.

The time for
this worke.

The time fit for this Apertion, *Hippocrates* elegantly describeth, where he saith, *Dropſie Bodyes muſt preſently be cut, and thoſe that are Empui. preſently burnt.* This preſently, *Hippocrates* himſelfe interpreteth to be, *out of hand, or in the beginning of the diſeaſe.* *Galen* ſaith, it muſt be *before the inward parts are corrupted*; for the Water is in vaine let out, if the Entrals be vitiated, eſpecially any thing notably; becauſe it will inſtantly and continually gather againe. So then it is a foule error in a deplorate or deſperate Dropſie, to vndertake this kind of Cure, becauſe (as *Ceſus* very well ſaith) it is a kind of impietie in Art raſhly or inconfiderately to prophane ſuch remedies, as being rightly vſed may be of great auaille.

The place.

The third Queſtion is concerning the place for this Apertion. *Paulus* and all Phyſitians after him, euen to theſe times, adminiſter this Section a little below the Nauill towards the ſides, becauſe of the *Tendons* or *Chordes* of the Muſcles: and that on the ſide that is oppoſite to the part affected; as if the Liuer be affected on the left ſide, if the Spleene on the right. That kind of Section is not to be diſcommended, yet *Laurentius* thinketh, it may be more commodiouſly done through the very Nauill, and for his oppinion bringeth very rare obſeruations, and ſtrong reaſons.

Aponcuroſis.

Laurentius his
new conceit
eſtabliſhed.

By Hiſtorics

Antonius Benneuenius recordeth, how a certaine Dropſie Patient being giuen ouer by the Phyſitians, by a raſh and caſuall aduenture recovered his health. For, when he was exceedingly dry (as is vſuall in that diſeaſe) and in deſpaire of recouerie, he poured in an abundance of Water, whereupon his Nauill ſuddenly opened, whence iſſued ſo great quantitie of the Dropſie Lye, that his Body fell to the wonted ſcantling, and he being aſſiſted by a diſcreete Phyſitian, recovered his health.

I ſaw (ſaith *Laurentius*) at *Mompelier*, a Dropſie Woman, whoſe Nauill in a tempeſtuouſ night, when ſhe thought little of it, opened, whereout flowed a great ſtreame of Water: early in the morning I was ſent for, together with *Bartholmew Cabrolins* a ſkilfull Anatomist: we found her Spirits almoſt ſpent by reaſon of the ſuddaine and immoderate euacuation; thoſe we preſently gaue order to reſreſh and re-eſtabliſh: which being done, ſhe perfectly recovered through Gods helpe, and yet continueth in good health.

Ludouicus Villonouanus a very learned Phyſitian, told me at *Gratianopolis* (ſaith *Laurentius*) that he knew a Country Peaſant perfectly cured by this kind of Section.

Balthazar Garielus my friend, and a learned Chirurgicalian of *Mompelier*, at my appointment, ſaith the ſame *Laurentius*, opened after this manner a Dropſie Patient, who was very importunate vpon vs; his Belly fell almoſt vnto the accuſtomed extent, and he ſeemed to be paſt all feare of Death. The tenth day after his Section, without any knowledge, he ate a pound of Cherries, hereupon he fell into a ſcouring, by which the frame of Nature was vtterly ouerthrowne, and ſo within two dayes he dyed.

By Reaſons

It is manifeſt therefore by experience, that this way Section may be ſafely adminiſtered: neither doth Reaſon diſſwade from it. For, as *Hippocrates* ſaith, *The way that Nature inclineth the Phyſitian muſt follow*; but Nature often-times findeth this way through the Nauill. Beſide, this kind of Apertion of the Nauill, excuſeth the Section of many parts. For, about the Nauill, doe meet the foure Nauill Veſſels, which if they chinke or cleaue, as they vſe to doe by the forcible confluence of Water to that part in Dropſie Bodyes, then there remaineth nothing to cut, but onely the Skin, and then the Water will iſſue forth.

Obiection.

But it will be obiected, that the *Chords* or *Tendons* of all the Muſcles of the *Abdomen*, doe meet about that place, and therefore if that place be wounded, it is a venture but Conuulſions will follow.

Answer.

We confeſſe indeed, that all the extreamities of the Muſcles doe determine in the White Line, but theſe extreamities about the Nauill are perforated, to make way for the Vmbilicall Veſſels, and therefore are not wounded in this kind of Apertion. Moreouer, thoſe which labour of this kind of Dropſie which is called *Aſcites*, almoſt all haue ſtrutting or ſwollen Nauils, the Tumor growing by reaſon of the confluence of Water to that part, ſo that if but the Skin be pierced with a ſharpe Inſtrument, then preſently followeth a Flood of Waters. Again, when the Section is thus made in the middeſt, the Patient may with eaſe lye vpon either ſide, which he cannot doe if the other kind of Section be adminiſtered.

The

The last question, was moued about the manner of this kind of *Paracentesis*, which is on this sort: You must first cast a Bought or running knot round about the Nauill, that at your pleasure you may streighten the hole or passage, if the Water should issue out with too great violence: next, with a sharpe pointed Nall or Bodkin, you must pierce the Skin in the very middle of the knot of the Nauill, against which, as we haue said, the Vessels doe chinke or cleaue in Dropsie Bodyes; and then put a Brazen or Siluer Pipe into the wound, through which the Water may passe, which also may be stopped at your pleasure; for all the Water must not at once be drawne out, but some and some by degrees. For *Hippocrates* saith, *That if the Dropsie water, or the Purulent Matter of an Empyeme in searching or cutting doe all at once issue forth, the Patient will dye*: For, it is a rule, *That all plentifull and suddaine Euacuations are dangerous*. And in another place, *Dropsie Waters must be by degrees euacuated*. Finally, it may seeme, that *Hippocrates* had some knowledge of this Apertion, because he saith in one place, *Apply your actuall Caustic about the Circumference of the Nauill, so let out your Dropsie Water, but burne not the part too deepe*. Haply, least they should not bee able to moderate the Effluxion.

The manner how to administer this kind of Apertion.

A caution.

Aphor. 27. Sect. 6. Aphor. 51. Sect. 2.

De Morbis Internis. De Locis in Homine.

The end of the Controuersies of the second Booke.

Of the Parts belonging to Nutrition or Nourishment.

THE THIRD BOOKE.

The Preface.

Having in the former Booke dismantled this Castle of the Body, and particularly the lower Region, we are now arrived at that Worke-House of Nature, wherein she hath built her Engines and Instruments by which she doth not onely nourish and sustaine the whole Family, but also perpetuate *Mankind* by propagation; the destiny of the Matter not admitting a perpetuities in the particular Creature. But because these two workes of Propagation and Nourishment are altogether distinct, if not in the Faculties being both naturall Alterations; the one called Generation, the other Assimilation; yet in the parts and organs thereto belonging: we have also thought good to divide them in our Discourse; and referring the worke of Propagation to afterward, in this place onely to handle the parts serving for Nutrition or Nourishment.

Seeing therefore the substance of the whole Body hath a necessarie diffuence and dissipation, as well by the in-bred heat, which like the greene Worme feedeth vpon the choicest Gems and Flowres, even the Radicall moisture, as also by the outward Aire, and other externall causes, and therefore cannot possibly either encrease to the iust extent or consist when it is growne, vnlesse the detriment and scath which is sustained by such dissipation and dissolution be restored and made good: Nature hath provided certaine nourishing Organs whereby that daily expence is continually supplied. And herein we have to admire the wonderfull providence of the great Creator, who hath disposed these parts wherein it was necessarie there should be such a confluence of noysome excrements in the lowest place, as it were in the Sinke of the Body, least otherwise their offensive exhalations should defile the Braine and the Heart, which are the Seats of the principall Faculties, or vitiate and disturbe the rest of the Senses. For this lower Region, is as it were the Kitchen of the House in which there are some parts, which as Cookes doe prepare the common dyet for the rest. But in the description of this Region, it must be remembred that we must not follow the order of Dignitie, or of Nature, but of Dissection, taking the parts according to their Position.

The Eye therefore falleth first of all into the snare of the Kell, and indeed it is of all things most like vnto a Snare or Purfenet, the close Meshes whereof, are purfled with curled Veines and curdled or crisped Fat, so becomming a thrummed Rugge to keepe warme the Membranous and vnbloody Guts and Stomacke vnder it. As for his duplecation, wherein the snaking and snayling diuarcations of the Vessels doe craule all ouer the Belly, I suspect it to haue beene ordained by Nature, for some more secret and mysticall end, then the securing of those tender Saplings, albeit I rest herein vnstatisfied for any thing I haue read.

Immediately

Immediately vnder these Cipresse wings (for wings they are called by the Anatomists) or Cauly cobwebs, appeareth the Maze or labyrinth of the guts wheeled about in manifold foulds and conuolutions, that neither the aliment should so suddenly passe away, and so the wombe of man become an insatiate Orque voyding whilst it doth deuour, neither yet the noisom steame of the Feculent excrements haue free and direct ascent to the vpper parts, but be intercepted and detained within those Meanders, and so smothered in those gluphs of the Guts, or let out at the port Esquiline. In the middest of the Guttes is scituated the Mesenterie, which we may call not the Midriffe, but the Midruffe, for it is most like vnto a gathered ruffe, sustaining the winding reuolutions of the Guttes in their proper places, & conuaying vnto them the Meseraicke veines, by which as by tender bearded rootes, the Aliment is conuayed vnto the gate of the Liuer: some haue called them *Baiuli domus*, the Porters of the house, because they continually carry the Aliment vnto that furnace, where it is tryed into blood. Neither are they idle and rigid passages, but as *Homer* feigneth that the instruments of *Vulcan* are moued by instinct and of their owne accord, so we may say that these vessels are taught by their Creator, not onely to leade along the *Chylus*, but to draw it and prepare it for the Liuer.

Next appeareth the *Pancreas* which wee call in Swine the Sweet-bread, a rude and vnshapely lumpe, most like a map or dish-clout, both in fashion and vse; or if you would liken it to any thing in the body, then it neereft resembleth the Liuer or cake of the wombe, which groweth to the rootes of the Infants nauell. It serueth for a pillow or Cushion, to boulder out the manifold diuisions of the Veines, Arteries, and Sinewes, which in that seat of the body are distributed vnto the adiacent parts; beside many other vses which we refer vnto their proper place: and passe along vnto the stomacke, the Cooke-roome, where Diet is the Steward, Appetite the Clark, and Concoction the maister Cooke. From thence the viands are deliuered vnto the Liuer, the principall part of this lower region, wherein they attaine their vttermost perfection, being depurated, from the scum by the bladder of Gall, from the residue by the spleene, from the vnprofitable liquor by the kidneies, which conuay it vnto the Cesterne of the bladder, to be cast out by the Conduite. Of all which if I should in this place vndertake to discourse, as it were easie for me, though briefly as I begā, yet the shortnesse of the partes of such discourse I see well would amount vnto too long a summe to bee comprehended in a Preface, especially considering wee shall at large prosecute euery particular in the following discourse: wherefore after we haue given you another kinde of distribution of them in the Chapter following, we will apply our selues vnto their particular Histories.

CHAP. I.

A distribution of the naturall parts contained in the lower Belly.

Having already intreated of the Inuesting or Contayning parts of the lower region or nether Belly, it followeth now that we continue our discourse to the parts contayned also. These are of double vse, for either they serue for nourishment, or for generation; those that belong to generation and propagation of the kinde, we refer vnto the next Booke. The nourishing parts doe either perfect the Chylus which we call Chilification, or the blood which we call Sanguification. For the first, some make and concoct the Chylus, as the stomacke; some helpe and further this concoction, as the Kell and the sweet-bread; others put to the last hand of perfection, and then distribute it, as the small guts; others receiue and auoyde the grosse and thicke excrements, as the great Guts and these together with the small, are fastned vnto the Mesenterie.

For Sanguification, some parts sucke the Chylus out of the Guts, alter it and giue it a certaine rudiment or tincture of blood, as the Meseraicke veines, which also carry it by the Port veine, vnto the gate of the Liuer, and thence into the substance thereof, where it receiue the perfection of blood. Others when it is thus perfected, doe distribute it into the whole body, as the hollow veine by his faire forked branches. Others receiue the excrements, either yellow choller, as the Bladder of Gall, and that which we call *Polus Biliaris*, & conueyeth it into the Guttes; or blacke and feculent choler, as the spleene or Milt, in which it receiue a farther concoction; and the more laudable part it referueth for his owne nourishment,

rishment, but the very Lees it sendeth away either vpward vnto the stomacke by a short vessell called *Vas breue*, where it becommeth the Appetites remembrancer; or downward to the *Hæmorrhoidall* veines. Finally, the ferous or wheyie part of the bloud is still distilled away by the Kidneyes, wherein there is a segregation or separation made of that whay or vrine from the bloud; the bloud remaining behind for the nourishment of the Kidneyes, but the whay is deriued by the vreters into the bladder, from whence it is deliuered out by the Conduite.

Of all which parts we will entreat as I said before, according to the order of Dissection, beginning with the Kell or *Omentum*.

CHAP. II.

Of the Omentum or Kall.

The names
& the reasons
of them.

The Kall or Kell which is deciphered in the sixt Table of the second booke, and in the first and second of this third booke, is called *Omentum*, as it were *operimentum*, that is, a couering: of the Greeks *ἐπιπλωον* of *ἐπιπλωω* to swim vpon, because it swimmeth vpon the bottome of the stomacke [Table 2 bb] and the vppermost guts [Table 2 cc.] From the wandring and implicated passages of his vessels, which may bee likened to a fishers net [Table 1. Figure. 1. and 2.] it

the stomacke. *HHH*. The lower part of the inner kall arising in some sort from the colick gut. *III*. The remayning portions of the vpper membrane of the kall torne off, that it may be shewne how the kall may be compared to a satchell or bagge.

Table 1. Lib. 3. The first figure sheweth the Kall or Omentum, whole and doosed on euery side, resembling a Satchell, or a small fishers Net; with the course of the Veines, Arteries, and Sinewes, running through it. The second figure containeth the lower membrane of the Omentum, the vpper being remooued with the Collicke gut which it containeth and the vessels.

- aaaa*. The outwards face of the vpper membrane of the Kall.
- bbbb*. The circle or girdle of the kall at which it growes.
- ccc*. The vpper part of the lower membrane about the colon.
- d e f*. Sheweth the membrane, vessels, and fat of the Omentum.
- g*. The trunk of the gate veine where it commeth out of the Liuer.
- h*. An arterie with a nerue reaching to the hollownesse of the Liuer, and the bladder of gall.
- i*. A vessell coming to the pylorus, especially on the back-part hauing an artery his companion.
- kk*. A vessell with a nerue which goeth to the right bottom of the stomacke.
- l m m*. Branches inwrapping the body of the stomacke from a vessell marked with *k*, which also goe through the vpper membrane of the kall *mm*.
- n*. A vessell reached out of the duodenum, and to the beginning of the empty gut, oftentimes hauing a small nerue to beare him company.
- o*. The diuision of the gate veine into the right and the left branch.
- p*. The right branch running into the mesentery and the guts.
- q*. A veine going to the backe parts of the stomacke.
- r*. A veine embracing the left mouth of the stomacke, in manner of a crowne.
- s*. The artery of the mesentery.
- u*. An artery going to the lower membrane of the kall.
- x*. A vessell sent with a nerue to the colon and to the lower membrane of the kall.
- y*. A vessell going to the lower Omentum.
- yy*. The course of the vessels of the spleene from the spleenicke branch.
- z*. A branch reaching to the left bottom of the stomacke.
- aa*. The Pancreas or sweet-bread vnder the vessels and the duodenum.

The second Figure.

- AA*. The vpper part of the lower kall arising from the back, which behind is vnder the stomacke, and with two membranes comprehendeth or embraceth the colon at the bottom of the stomacke.
- B*. A veine coming from the left trunk of the gate veine and the arterie, with a nerue for the most part tied vp to it, going into the kall.
- C*. A notable veine and an arterie communicated to the kall and the collicke gutte, to which a small nerue is added in some steads.
- D*. A veine running along the left side of the kall.
- E*. The right side of the collicke gut which lyeth vnder the hollownes of the liuer here cut away.
- F*. The left side of the collicke gutte which lyeth vpon the spleene.
- GG*. A part of the collick gut running along vnder the bottom of the stomacke.

is

is called *rete* or *reticulum*, for that saith *Archangelus*, as a net intangleth the fishes, so in this Membrane the Fatty vapours are intercepted and stayed. The Arabians call it *Zirbus*, the Latines *Mappa ventris*, the dish-clout or map of the Belly, because it licketh vp the superfluities thereof. All the sanguine or bloody parts almost are couered heerewith, but ouer some it is more fatty, ouer others more membranous. Amongst all creatures it is greatest in Men and Apes; and of Men, those that liue a sedentarie and idle life, sacrificing to their appetites, haue it so great, that it becommeth a burthen vnto them, whereupon they are called *Epiplocomista*, that is, Kal-carriers: but those that vse great exercises, as Hunters and such like, haue it more membranous, and lesse fatty.

It is a large membrane, scituated before vpon the bottome of the stomacke, [Tab. 6 PP. Fig. 2.] and downeward ouer the guts [Table 6. KKKK Fig. 2.] vnto the Nauill. Sometimes, but seldome, and that in Apes and Dogges it is stretched euen vnto the sharebone; and vsually in dissections it is obserued to bee rowled vp, or doubled towards the spleene, not onely in such as are hanged or drowned sayeth *Vesalius*, but also in those that dye of other ordinary diseases, or come to their ends by sodaine mischances. Sometimes also it insinuateth it selfe into the conuolutions or windings of the guts, and sometimes in Women it passeth betweene the bottomes of the wombe and the bladder, and by straightning the mouth of the wombe becommeth an ordinary, but yet not a perpetuall cause of barrenesse or sterility, as also *Hippocrates* obserued in his booke *de natura Muliebri*. In some women after their trauell, it remaineth gathered together about the middle of their Bellies, and there is the cause of sore paynes. But if it fall into the passage that descendeth into the Cod, it causeth a soft rupture, which disease no creature is subiect vnto but Men and Apes, as sayeth *Galen* in the third Chapter of his sixt booke *de administrationibus Anatomicis*.

It is fastned alwayes to the stomacke [Table 6. MN O Fig. 2.] to the Spleen and the Collicke gut [Tab. 1. Fig. 2. GG HH] to other parts sometimes it is ioyned, sometimes it is free from them, for it behooued not saith *Galen* in the 11. chap. of the fourth booke *de usu partium*; that it should hang loosely, lest it should be crumpled together, and should leaue many parts vncouered, which stand in neede of his warmth.

The forme of it is likest to a Purse-net or Faulknors bagge, [Table 1. Figure 1. and 2. 11] consistng of a double membrane knit together in the bottome; *Columbus* saith, but onely reflexed or turned backe againe. It hath a round orifice [Table 1. Figure. 1. bb] which ascendeth higher in the hinder part then before, and belowe it is round [Table 1. Figure 1. and 2.]

It is compounded of membranes and vessels, and a muddy and easily putrifying Fatte, which composition *Galen* expresth vnder the name of his original, in the place next aboue named. The Membranes are two (whence of some is called a double *Peritoneum*) and those very fine and smooth (least the guts should be ouer burdened with his waight) lying one vpon the top of another; the vpper is called the vpper wing, the lower the lower wing [Tab. 2. cc.] The vpper and formost ariseth at the bottome of the stomacke [Tab. 2. aa. bb.] from the *Peritoneum* which compasseth it about, and maketh his third coat, and is ioyned in a right line, with a portion of the inferiour membrane in the hollow parts of the Liuer and the spleene. The lower and hind-most wing ariseth from the *Peritoneum* at the backe [Tab. 1. Fig. 1. ccc] presently vnder the midriffe; and being led to the hollow side of the liuer, it cleaueth (yet but seldome) to a part of it, as also to the midriffe, to the right side of the stomacke, almost to the whole gut called *duodenum*, and to the hollow part of the spleene; and groweth fast to the stomacke, and to the collicke gut, [Tab. 1. Fig. 1. GG.] all the way the same is annexed to the bottom of the stomacke, so that to that gut it is as it were [Table 1. Fig. 2. HH] a mesenterie. In Dogs it is neither tyed to the Colon, nor to any other gut; in Apes onely to the right part of the Colon.

Many veines (but onely from the port veine) passe through both his wings. Through the vpper from two veines which passe by the bottome of the stomacke (which are called the right and left [Table 2. H and X] *Gastra epiplois*) infinitely propagated obliquely downward. [Table 1. Fig. 1. KK MM.] Through the lower wing from those veines which passe into the spleene [1. Fig. 1. u x Fig. 2. BC D] which are diuersely spread, sometimes with a foure-fold branch (as in the history of the Port veine shall bee sayd) for the nourishment of the adiacent parts.

They are sprinkled also with many Arteries [Tab. 1. Figure 1. u Figure 2. c] from the Celiacall

kk. The two vmbilicall arteries.

Nerues.

liacall and mesentericall branches to giue them life; but their nerues from the Ribbe-branch [Table 1. Fig. 1] of the sixt paire are wondrous small, but finely scattered that they might not be altogether without sence.

The fat of the Kell.

The Fat is very plentiful about the vessels [Tab. 1. Fig. 1. d e f] but in the distance betwixt them, none at all. In an ordinary fat man it may amount to a pound, or a pound and a halfe; and amongst it do runne innumerable glandules or kernels, which sucke vp the faeculent moysture, which is separated in the first concoction. Wherefore seeing it is not ingendered of any portion of the blood, as that fat called *pinguedo*, or as other fats, therefore it easily putrifieth, so that if vpon a wound it fall out of the body, it becommeth presently rotten, which hapneth not to the other fats vnder the skin, or in other parts.

The vse of the fat of the Kell.

The vse of the Fat of the Kall, is to cherish and to comfort the bottome of the stomack, (for the vpper part thereof is warmed by the Liuer which lyeth vpon it, and therefore it is that the Kall attaineth not so high) as also to increase the heate of the guts: for both these parts are membranous and without blood; and therefore their naturall heate is but weake. Now this comfort the Kall affoordeth not onely by his owne heate, which yet is the more, because of the manifolde Veines and Arteries which are wouen together through his substance: but also because beeing thicke and bedded together, it much hindereth the heate from dissipation, and the incursion also of outward colde, and so by consequence is a great helpe and furtherer of concoction. And that it was ordayned to increase heate, *Galen* in his fourth Booke *de vsu partium*, and in the ninth Chapter, maketh manifest by the example of those, who hauing got a deepe wound in their bellies, so that a part of the Kall falleth out, do euer after worse concoct their nourishment, and stand in need of Stomachers or other coverings vpon their bellies to keep them warme, especially when much of it falleth out; for

for it presently groweth liuid, & constraineth the Chirurgion to take it off, so saith *Hippocrates* in the beginning of his first Booke *de Morbis*, If the Kall fall out, it putrifieth necessarily. And *Galen* in the place before named saith, he tooke almost all of it from a Fencer, who was presently cured, but euer after was easily offended with colde, so as he was constrained to defend his belly with Wooll. Heereto also *Aristotle* assenteth in the third Chapter of his fourth Booke *de partibus Animalium*, Nature (saith hee) abuseth the Kall to helpe the concoction of the Aliment, that it might be done with more ease, and greater expedition. For heate concocteth: now that which is fat is hot, and therefore the Kall beeing fat, must needs concoct.

Hippocrates
A story out of
Galen.

Aristotle.

Another vse of the Kall is to keepe the guts moyst, because they are often distended, and againe corrugated, as they are filled with *Chylus*, or emptied of it againe. A third vse is, that in time of necessity and affamishment, saith *Galen* in the xi. Chapter of the fourth Booke *de usu partium*, it might supply a kinde of subsidiary nourishment to the naturall heate.

Galen

The vse of the Membranes of the Kall or Kell, is to sustaine the branches of the Gate Veine, & the Cæliacall Arterie which passe into the Stomacke, the Spleene, the Gut called *Duodenum*, and the Collicke gut. Againe, to knit the stomacke, the *duodenum*, and the Collick guts vnto the backe. To couple together the Liuer and the Spleene.

The vses of the
Membranes of
the Kell.

Archangelus addeth, That the thicke and bloudy vapours arising from the parts contained in the lower belly, might cleaue into these Membranes, and by their density and thightnesse or fastnesse be condensed or curdled into fat, that so good a vapour as might afterward bee turned into nourishment, should nor vapour out in vaine. Finally, *Laurentius* addeth another vse of the Membranes out of *Hippocrates* Booke *de Glandulis*, That when the humour which commeth from the Guts, is so plentifull that it cannot be receiued and assumed into the Glandules, the ouer-plus might be referued in the Membranes of the Kell.

Archangelus

Laurentius out
of *Hippocrates*.

CHAP. III.

A briefe Description of the Gate-Veine and his Branches.

Now because the branches of the Gate-veine, and the Cæliacall or Stomacke Arteries must be demonstrated by order of Dissection before we come to the Guts, or else they will be offended, I haue thought it not amisse to giue you a briefe description of them in this place, referring the larger and more exact discourse vnto the proper history of the Veins and Arteries. First therefore the Gate-veine (so called, because through a gate the Chylus is conueyed into the Liuer) ariseth out of the hollow part of the Liuer, betwixt the two small eminencies or swellings thereof which *Hippocrates* calleth *Portas* the gates. Some thinke, it is propagated from the vmbilical veine which proceedeth out of the cavity. We will diuide it into the Trunke and Branches. The trunk before it is diuided [Tab. 3. B] sendeth forth two small shootes from his fore-part called *Cystica Gemella*, or Twin-veines of the Gall, [Tab. 3. CC] which passe vnto the bladder of Gal. The second is called *Gastrica dextra*, the right stomacke Veine [Tab. 3. D] which goeth vnto the backe part of the stomacke, and the *Pylorus* or mouth of the same.

Why we treat
of them in this
place.

The Originall
of the Gate-
Veine.
Banhuine.

Cystica gemella

*Gastrica dex-
tra*.

The branches are some of them vpper, some neather. The vpper branches which we call the roots of the Gate-veine, [Tab. 3. AAAA] are disseminated through the hollow part of the Liuer, and do make one Trunke [Tab. 3. BCDE] These roots are by *Anastomosis* ioyned with the roots of the hollow Veine.

The nether brances shoot out on the right side or on the left, from the right side three branches.

The first, called *Gastroepiplois dextra*, the right stomacke and Kall veine [Tab. 3. H] attaineth from the right side of the trunk, to the bottome of the stomacke, and the vpper membrane or wing of the Kall.

*Gastroepiplois
dextra*.

The second is called *Intestinalis* or the Gut-veine [Tab. 3. I] because it is conueyed vnto the middle of the *duodenum*, and the beginning of the *Jejunum* or empty gut.

Intestinalis.

The third is called *Mesenterica*, or the veine of the Mesentery [Table 3. b.] which is subdivided into three veines: two of the right hand called *Mesenterica dextra*, which are distributed into the guts called *Jejunum*, *Ileon*, *Cæcum* and a part of the collick gut, where becomming very slender and fine like bearded roors of a tree; they make those veines which we commonly call the Meseraick veines [Tab. 3. dddd] which passe between the two mem-

*Mesenterica
dextra*.

Table ij. sheweth the Vena porta, or Gate-veine with his branches, which he sendeth to the bladder of Gall, to the stomacke, to the Splene, to the mesentery, and to the Guts.

TABVLA III.

- 1, 2, 3, 4, 5. The vpper branches of the Gate-veine, disseminated thorough the Caud of the hollow parts of the Liuer. *AAAA.* Their distribution maketh the forme of the Liuer.
- B. The trunk of the Gate-veine coming out of the hollow part of the Liuer.
- CC. The two twin veines of the Gall, called *Cystica Gemellæ*.
- D. The right *Gastrick* or stomacke Veine.
- E. The diuision of the trunk of the Port-veine into two branches.
- F. The left branch, which is the vpper, and is called the Splene branch.
- G. The right branch, which is the greater and the lower, called the Mesentericall branch.
- H. The right stomack Kall-veine, called *Gastroepiplois*.
- I. The Gut-veine called *Intestinalis*.
- K. The lesser stomacke veine, called *Gastrica minor*.
- L. The right Kall-veine called *Epiplois dextra*.
- M. The sweet-bread-veines called *Pancrea*.
- N. The great stomack-veine called *Gastrica maior*.
- OO. Two veines of the last named branch, inwrapping the backside of the stomacke.
- P. The Bifurcation or partition of the great stomacke-veine in the vpper part of the stomacke.
- Q. The Crowne veine of the stomacke called *Coronaria stomacica*.
- R. A branch of the Crowne-veine passing along the vpper side of the stomack, and giuing branches to the *Pylorus* or mouth of the stomacke.
- S. The backward or hinder Kall-veine called, *Epiplois postica*.
- T. The diuision of the Splenicall branch.
- V. The left Kall-veine called *Epiplois sinistra*, whose root in the great figure is at V. but his distribution is well shewne in the small figure by V. and T.
- X. The left stomack-kall veines, called *Gastroepiplois sinistra*.
- YZ. The veines which runne vnto the left side of the stomack turned backe from them which go vnto the vpper part of the Splene, and the vpper Z. of the two sheweth the vessel called *Vas breue* or the short vessel, whereby the melancholy passeth out of the Splene into the stomack, and this is the reason why melancholy people haue alwaies crasie stomackes.
- aaaa. Small branches running through the substance of the Splene, making the forme of the splene.
- b. The right Mesentericke veine.
- c. The left Mesenterick.
- ddd. The Mesentericall veines.
- ee. The Veine which belongeth to the Collick gut.
- ff. Veines belonging to the right Gut.
- gg. The Hemorrhoidall veines which compasse the Fundament; but these shall bee more lively described heereafter.

branches of the Mesentery, and gaping with open mouth at the coate, not at the cavity of the Guts; do sucke from them the *Chylus*, to which they afford a certain rudiment or beginning of blood, and then conuey it to the Liuer, or rather into the rootes of the *Porta*, which are disseminated in the Liuer. From whence a part falleth out into the substance of the Liuer for his Nourishment, the rest is driven into the hollow Veine, to be communicated to the whole body. Moreouer we must know, that the very same Mesentericke veines which carry the *Chylus* thus vnto the Liuer, do also bring from the Liuer vnto the Gutes, perfect blood for their nourishment at the very same time; the veines of the Liuer drawing the *Chylus*, and the Gut drawing the blood.

The third Mesentericall veine, is called *Mesenterica sinistra*, and is disseminated into the left [Tab. 3. C] and middle part of the mesentery. From this commeth the *Hemorrhoidalis interna*, the inward Hemorrhoidall vein, [Table 3. gg] (for the externall proceedeth from the Hypogastricall branch of the hollow Veine) and descendeth by the end of the Collicke [Tab. 3. ff] vnder the right Gut, whose extremity it compasseth with small Tendrils, by which the Hemorrhoides do flow. And thus much of the branches which proceede out of the right side of the trunk of the Gate-veine.

Out of the left side issueth the splenicall bough, and from it many propagations, some before

Mesenterica sinistra.
The Hemorrhoid. Veines.

Mesenterica sinistra.

fore, some after his diuision: before his diuision spring five branches.

The first called *Gastrica minor & sinistra*, the lesser and left stomacke veine [Table 3. K] *Gastrica minor* goeth vnto the back part of the stomacke.

The second called *Gastrica maior* [Tab. 3. N] creepeth vnder the stomacke to his vpper orifice with three branches; the middle of which is called *Coronaria Stomachica*, the Crowne veine of the stomacke [Table 3. Q] because it doeth incompass the vppermost mouth thereof.

The third is called *Epiplais dextra*, the right Kell veine [Table 3. L] this attayneth vnto the right side of the lower wing of the Kell and to the Collicke gut. *Epiplais dextra*

The fourth called *Epiplais postica*, the backward Kell veine [Table 3. S] passeth with a double branch, one on the right hand, another on the left, to the vnder wing of the *Omentum* or Kell, and a part of the Collicke gut. *Epiplais postica*

The fift is manifold, called *Pancrea* [Tab. 3. M] because like smal haire they passe vnto the *Pancrea* or sweet-bread; and these are the branches which doe issue before the diuision.

After the diuision from the vpper braunch neere the superior part of the spleene, springeth a notable veine, commonly called *Vas breue*, the short vessell [Table 3. Z] which is inserted into the left side of the bottome of the stomacke, by which the melancholy bloud is belched out into the mouth of the stomach, to strengthen it by his adstriction, to further the principall action of the stomacke which is concoction, and to prouoke appetite. *Vas breue.*

From the lower branch proceed two veines: the first called *Epiplais sinistra*, the left kel *Epiplais sinistra* veine [Table 3. V] which passeth to the left side of the lower wing of the *Omentum*.

The second is called *Gastro Epiplais sinistra*, the left stomacke and Kell veine [Tab. 3. X.] *Gastro epiplais sinistra.* It ioyneth it selfe with the right, and compasseth the bottome of the stomach; the remainder of them both after their copulation, is diuersly distributed [Tab. 3. YZ] into the middle line of the spleene: and so much of the Gate veine and his branches.

CHAP. IIII.

Of the Arteries called *Celiaca*, and *Mesenterica*: that is, the Arteries of the Stomacke, and the *Mesenterie* which accompany the branches of the Gate veine.

HE Arteries which accompany the branches of the Gate veine before described are three. The first is called *Celiaca*, or the Stomacke Arterie [Tab. 4. Fig. 1. m] and the other two, *Mesenterica superior*, or the vpper *Mesenterical* Arterie [Tab. 4. Fig. 1. n] and the lower [Tab. 7. 10.] called *Mesenterica inferior*.

The *Celiacall* or Stomacke Arterie [Tab. 4. Fig. 1. m and Tab. 7. 6] is so called because it sendeth many branches to the stomach. It is a notable branch of the great Arterie, and every where accompanieth the branches of the Gate veine. His originall is from the foreside of the *Aorta*, where it leaneth vpon the back-bone, and is supported with the lower wing of the Kell, till it come to be diuided into two branches: the right [table 4. Figure 1. n] is lesser, and the left [table 4. Fig. 1. n] somewhat larger. *Celiaca.*

The Right branch [table 4. Figure 1. n] [as it goeth vpward to the hollownesse of the Liuer, sheddeth small furcles out of it selfe, some from his vpper part, and some from his lower. The right branch.]

From his vpper part two: First, the right *Gastricke* or Stomacke Arterie [table 4. Figure 1. p] is distributed into the lower part of his right Orifice. Secondly, *Cystica gemella* [table 4. Figure 1. f Figure 2. x. table 7. 8.] two small Arteries creeping to the bladder of gall. *Gastrica dextra.* *Cystica gemella.*

From his lower part three: First, the right Kell Arterie [table 4. Figure 1. o Figure 2. h] attayning to the right side of the Kell and the Collicke gut. Secondly, the gut Arterie [tab. 4. Figure 1. q Fig. 2. d] reaching to the *duodenum* and the beginning of the *Ieiunum*. Thirdly and lastly; the right stomacke and Kell Arterie [table 4. Figure 1. r] which is fastned to the vpper Kell, and sprinkleth many branches to the foreside and backside of the bottome of the stomach. *Epiplais dextra.* *Intestinalis.*

That which remaineth of the right branch, determineth in the hollow of the Liuer [tab. 4. Figure 1. y table 7. 7] by which it recciueh life. *Gastro epiplais dextra.*

The left branch [table 4. Figure 2. n] called *Arteria splenica*, passeth obliquely through the *spleen*. *Arteria splenica.*

Table iij sheweth a part of the Trunke of the great Arterie, out of which the Arterie Calliaca proceedeth; and beside it sheweth the branches of the Calliaca Arterie, which do accompany the Branches of the Veine.

The second Figure sheweth the mutuall connexion of the Calliaca Arteries, with the sweet bread and spleene.

TABVLA III.

FIG. I.

FIG. II.

- g The arterie belonging to the short vessell which passeth from the spleen to the stomach, called *vas breue arteriosum*.
- m The place where the Calliaca Arterie ariseth.
- n The right branch of the Calliaca.
- r The right kal. arterie, as it is disseminated into the lower membrane of the Kall.
- p The right stomacke arterie running into the right side of the back of the stomach toward the *Pylorus*.
- q The gut arterie which reacheth to the gut called *duodenum* and to the beginning of the *scinum* or empty gut.
- r The right stomacke-kall arterie which is disseminated into the right side of the bottome of the stomacke, and into the vpper membrane of the kall.
- f The two twin arteries of the gal, how they passe vnto it.
- e Arteries distributed into the hollow part of the Liuer.
- n The left branch of the Calliaca or *Aluna*, which goeth especially to the spleen.
- x The greater stomacke arterie which goeth to the hinder side of the stomach, and to his left orifice.
- y Certaine shootes sent into the middest of the stomacke where it is tied to the backe.
- e The Crowne arterie of the stomacke, which circleth the left Orifice of the stomacke.
- e The left stomacke arterie which goeth into the vpper parts of the stomacke at the right orifice.
- β The back or hindmost Kall arterie, which is distributed into the lower membrane of the Kall and the collick gut.
- γ The left kall arterie which goeth to the lower membrane of the kall.
- aa Branches which passe into the hollownes of the spleene.
- e The left stomack Kall arterie going to the left side of the bottome of the stomacke, and the vpper membrane of the kall.
- e The vpper mesentericall arterie.
- n The right and the left emulgent arteries as they goe to the Kidneys.
- xx The right and the left spermaticall arteries.

The second Figure.

- aa The veine, the arterie, and the nerve, which fould themselves in the *Pylorus* or mouth of the stomacke.
- b The lesser branch of the Gate veine, or the spleenick branch.
- c The greater branch of the Gate veine or the mesentericall branch.
- d A veine and an arterie going to the gut called *duodenum*.
- e Vessels going to the lower membrane of the Kall.
- f The roote of the arterie which accompanieth the branches of the gate veine.
- g The *Coronarie* or crowne veine and arterie of the stomacke.
- h Vessels going to the lower Kall, and to the collick gut.
- i The sweet bread or *Pancreas*, vpon which the vessels are for security distributed.
- k A veine going to the left side of the lower Kall.
- l A company of vessels which passe vnto the spleen.
- m The inflexion of these vessels.
- nnn Vessels reflected from the former, and offered to the stomach.
- ooo Veines and arteries sent to the gut.
- pp Two arteries going to the mesentery.
- rrrr The glandules or kernels of the mesentery, which lie vnder the vessels for their security.
- s The trunk of the gate veine.
- u The hole of the bladder of gall where it openeth into the gut called the *duodenum*.
- x The veines of the bladder of gall.
- y Arterie and nerves that go to the liuer and the bladder of gall.
- z Two branches which run vnto the back parts of the stomach.
- * The *Hæmorrhoides* veine and arterie.

the *Pancreas* [tab. 4. fig. 2. i.] to the Spleene. [table 4. fig. 2. m.] It is larger then the right branch, that it might not easily be obstructed; for it conueyeth vitall spirits to the spleen, & also belcheth out into it the more fæculent part of the bloud contained in the great Arterie. This Arterie is continually ioyned vnto the spleenick veine described in the Chapter going before, and hath so many branches, and in the same order of position, as also named by the same names, which we will runne breiefely ouer in this place.

Gastrica sinistra
Ar.

Gastrica sinistra vel minor, the left or lesser stomacke Arterie [table 4. figure 1. a] turneth on the right hand to the vpper parts of the stomacke.

Gastrica maior

Gastrica maior [table 4. figure 1. K] offereth a branch to the backside of the stomacke, as also to the midst thereof marked in the fourth Table at [y], out of this also ariseth the crowne Arterie [table 4. figure 1. 2.] answering the crowne veine before described.

From the lower part.

Epiplois postica

Epiplois postica [table 4. fig. 1. B. fig. 2. C] diuided into two stradling branches, which are propagated into the lower wing of the Kall and the Collick gut thereto adioyned.

Epi-

Epiplois sinistra [Tab. 4. Fig. 17] passeth also to the lower *Omentum*, and runneth into the left side thereof.

The remainder of this branch [Tab. 4. Fig. 17] attaineth to the Spleene, and is diuided into an vpper and a lower branch, and these into others, till at length they reach vnto the hollow side of the Spleene, [Tab. 4. Fig. 18] From whence [do] proceede *Gastroepiplois sinistra*, [Tab. 4. Fig. 18] which is sustained by the vpper wing of the Kell, and so goeth vnto the left side of the bottome of stomake.

Also *Vas breue Arteriosum* [Tab. 4. Fig. 17] passeth out of the vpper part of the Spleen, and is inserted into the left side of the stomacke.

The Mesentericall Arterie is double, both of them proceeding from the fore-side of the trunk, the vpper below the *Celiacæ*; the lower below the spermaticall Arteries.

The vpper [Tab. 4. Fig. 17] Fig. 2. P. Tab. 8, 10.] is propagated into the vpper part, and almost into the whole Mesentery, and reacheth his manifolde furcles to the empty gut, the *Ileon*, and a part of the Collicke gut, where it approacheth the right Kidney.

The lower [Tab. 4. Fig. 17] Fig. 1. Q, Tab. 8, 2] Mesentericall Arterie, runneth vnder the lower end of the Mesentery, and especially to the left side of the Collicke gut and the right gut, and maketh the Hemorrhoid vessell, together with the Veins, & it is noted in the second figure of this fourth Table at this marke*. And so much at this time shall suffice to haue spoken of the Gate veine, and the *Celiacall* Arterie in this place, considering that we shall haue fitter occasion to prosecute their branches heereafter. Now we will proceede vnto the guts.

CHAP. V. Of the Gutes.

THe Gutes are called in Greeke *ἔντερα*, and *Intestina* in Latine, because they are placed in the inmost part of the body, and doe take vp the most part of the cavity of the lower belly. [their naturall position appeareth in the 2. & 5. Tables,] And because they farre exceed the length of the same, they are necessarily gired and rouled into manifolde Conuolutions, [Tab. 2, 5, & 6.] that it might containe them, as we vse to rowle vp a rope if we would put it into a bag or quoye a Cable. They are knit together by the benefite of the *Mesenterium* [as appeareth in the 7. Table,] by which also, and the interposition of the *Omentum*, they are tied to the backe, and are held vp or supported by the cavities or hollownesse of the hanch bones.

They are long bodies, and commonly fixe times so long as the man whose entrals they are, round they are and globous, that they might bee more capacious and lesse subiect to outward iniuries; Hollow, but not all of a bore as wee call it, carried also in circular conuersions (excepting their beginning [Tab. 6. Fig. 1, 2. at 1 and A] and their end, that the entrance and out-gate of the Aliment should not bee interrupted) lest the nourishment should too suddenly slip away before the *Chylus* be fully distributed, and constrain a man est-soones to call for more, and so be the cause of insatiable gulosity or raueness, which would, as *Plato* saith, interrupt all good and liberall learning. For so we see those creatures whose guts from the stomacke to the sledge are either streight or lax; are insatiable deuourers, which also *Aristotle* witnesseth in his third Booke *de partibus animal.* chap. 14. for the loosenesse or laxnesse of the gut encrease, and the rectitude of it hastneth the desire of meate. Wherefore those creatures whom it became to bee more moderate that way, haue more of these circumuolutions, which also make them able longer to containe the excrements, that they shold not be enforced but at their own pleasure to vnburden themselves; for those creatures that continually put in, must haue answerable euacuation.

The guts are continued with the stomack at the right Orifice called the *Pylorus*, but their substance is thinner then that of the stomack, and by reason of the innumerable veines that are inserted into *Ieiunum* & *Ileon*, which do in a short time suck it, they receiue much nourishment, which presently by as many vessels is conueyed to the Liuer. This speedy distribution of the nourishment could not be, if it went out of one stomacke into another, because there would not be space for the insertion of such a world of veines, and so the distribution must needs be slower, and beside much of the Aliment would escape the Veins, vnlesse it were est-soones all the way of the passage againe and many times as it were reui- sed, till there were nothing left but bare excrement.

And albeit there be but one *ductus* or through-passage from the *pylorus* or mouth of the stomack

The veines of the guts called Mesentericks.

stomacke euen to the sledge, that it may not amisse bee called one gut; yet because the parts of it do very much differ in substance, figure, office, place, magnitude, and in number of circumuolutions and turnings: therefore first in respect of their substance, there are two sorts of guts. One slender, fine, and small, which *Galen* calleth *μικρά τήλεα, λεπτά. Plan.* *tas* calleth them *Lactes* of the old word *Lacio*, which signifieth to draw, because they draw the *Chylus* more powerfully then the other which are thicke and crasse, called by *Hippocrates*

The small guts.

The slender or smallest sort of Guts is three-fold, *Duodenum*, *Jejunum*, and *Ileon*, which though they haue all almost one capacitie or amplitude, yet they are easily distinguished by their scituation, length, and by their Meseraick veines. And beside, the *Jejunum* about his beginning, where it is tyed to the backe, is sometimes obserued to be enlarged.

Tab. 5. sheweth the Bowels of the Lower belly, euerie one in their owne place. The ends of the lower Ribbes, together with the Midriffe and the Peritonaum adhering there to are turned backe, that the Liuer, the Spleene, and the stomacke might be better seene.

- A. The Brest blade cald *Cartilago ensiformis*.
 BB. The *Peritonaum*, together with the Midriffe and the broken ribs bent outward.
 CC. The *Gibbons* or buching part of the Liuer.
 D. A Ligament tying the Liuer to the Midriffe.
 E. A part of the vmbilicall veine.
 FF. The stomacke filled full of meate.
 G. A part of the Spleene.
 H. The blinde gut of the late writers: for the ancients tooke the top of the Colon for it.
 I. The beginning of the great or thicke guts.
 I. and so to K sheweth the passage of the Collick gut from the right kidney to the Liuer, and so the Collicke and the stone on this side are in one place, and therefore hardly distinguished.
 K. to L. the same Collicke Gut lyeth vnder the whole bottome of the stomach, which is the reason that those which are troubled with the Collick cast so much.
 L. to M. The passage of the Colon, from the spleene vnto the share bone by the left kidney a-way, which maketh the payne of the Stone and the Collicke on the lefte side, very, harde to distinguish.
 N. The Colon ending into the right gut.
 O. The beginning of the right Gut vnto the bladder.

 RST. The lesser Gutes, especially lying vnder the Nauell.
 aa. The two vmbilicall arteries.
 b. The bottome of the Bladder.
 * The Connexion of the bladder and the *Peritonaum*.

TABVLA. V.

The great guts.

The thicke or great guts are as many [Tab. 6 Fig. 2, 3.] called *Cacum*, *Colon* & *Rectum*, all differing in scite, figure, and maginitude. For the *Colon* and *Rectum*, that is, the Collick and the right guts, are more ample then al the rest. For the figure, some are right as it were by a line, as the *Duodenum* and *Rectum*, the rest are full of turnings, and as it were chambered more or lesse.

Their offices.

In respect of their offices, some are appointed both for the persifting and for the distributing of the *Chylus*, to wit, the smaller and narrower, that so the smallest crumme of the meate may meete with their sides and vessels; others are appointed for baser vse, to gather together the excrements, as the Crasse or thicke guts.

Their scituation.

The smaller, partly by reason of their excellency, partly for their commoditie, do occupy the middle place [Tab. 5. RST, Tab. 7. CCCC] euen all the Regions of the nauell & the *Hypogastrium*, yet in dogs it is not so, which deceived the Ancients, who called the small the

upper

upper guts, the thicke the lower; which order we finde different in man, whose Colon occupieth the vppermost place, and passeth vnder the bottom of all the stomacke. For their commodity they are placed neare the Center of the Mesenterie [Tab. 7. H] that the mesentericall branch might without any great distance be conuayed vnto them, and so the Chylus quickly transferred to the Liuer.

The thicker guts are placed towards the sides [Table 5. Table 6. Figure. Table 7. EEEE] partly because they might giue way to the smaller; (the Colon also is knit to the bottome [Table 5. E] of the stomacke) partly that like a munition or defence they might compasse and defend the smaller, least they should bee pressed or streightned. They were also made large, that they might containe the greater quantity of excrements, before they were provoked to excretion.

The first of the slender guts [Table 6. figure 1, from I to K] which Herophilus calleth *δωδεκαδάκτυλον*, in Latine *duodenum*, hath his name from the length of twelue fingers, which yet we finde it not to holde in our bodies; it may be, because now a dayes the stature of Mans body is much impaired. Galen calles it *ἐνδογαστρικόν*, as it were a production, to wit of the stomacke, which name yet some doe onely allow to the orifice of this first gut. This *duodenum* beginning on the right side, at the Pylorus [Table 6. figure 1, H] is reflected or turned backward, vnder the stomacke, that it may bee knit with membranous ligaments, to the spondelles or rack-bones of the loynes, to hold it straight and right downe; for if it should haue beene rowled and circled about, first the entrance of the Chylus should haue beene hindered, and then being gotten in, it would haue beene subiect to bee returned backe againe. Moreover, it would haue beene a hinderance to the veine that commeth from the Port or Gate of the Liuer, and to the Arterie which passeth to the Liuer: beside, indeede there is no space or scope for any such conuolutions or turnings in that place. It determineth vnder the Colon, about the beginning [Table 6, Figure 1, K] of his windings. It is the straightest of all the guts, that the Chylus should not suddenly and togetherward fall into it out of the stomacke; and some what thicker then the other two, because it receiueh a short veine from the trunke of the Port veine, which we called *intestinalis* [Table 3. I] or the Gut veine, (but no *mesentericall* veine at all) and an Arterie from the *Celiacall*; both which are led along according to the longitude of this Gut, to the beginning of the *Jejunum*. Vnder this the *Pancreas* or sweete bread lyeth, especially in Dogges, that it may boulder the vessels, and moysten or supple the gut with a slimie moysture.

The second small gut is called *ἰεῖον*, or the [Table 6. Figure 1, M] Empty gut: It is for the most part found empty, and that because of the innumerable *mesentericks*, and those very large, which ending in the inner coate of the gut, doe there gape with open mouth, and draw away the Chylus, as the nourishment fall lower and lower, till all the goodnesse bee drawne away. And if any part of the Chylus scape the first conuolution of this gut, yet the second or third will embrace it, till most of the profitable iuyce be drawne away by the *mesentericks* to this gut belonging; which suction or drawing is much increased by the vicinitie of the Liuer, and beside, the Aliment as it passeth by, being yet fluid, doeth easilie follow.

His beginning [Table 6. Figure 2. M] on the right side vnder the Colon, where the conuolution of the Gutes begin, is very liuid or blewe; when it commeth aboue the Nauill (whose whole region it taketh vp) being before wound vp into many circled labyrinths, it endeth into the *Ileon*. It is in length twelue palmes and three fingers. In breadth it exceedeth not the little finger, vnlesse it be puffed vp with winde. In the beginning of this *Jejunum*, or in the end [Table 6. Figure 1. I] of the *duodenum*, is the passage of Choller or Gall inserted, called *Porus Biliaris*; that after the Chylus is now fallen downe beneath it, the Liuer may vnburden it selfe by this vent of that humor, which by his *acrimonie* prouoketh the Guts both to expell the excrements containd in them, and to work downward the slimy phlegme that cleaueth vnto them; whence it is, that in dissections it is found more empty then the rest.

The third Gut is called *λεῖον* or *tenuis*, that is, slender, because of the tenuitie of his membranes; it is called also *εἰλόν* from a worde which signifieth to encompassse, as it were the circled gut; also *volutus*, because of his many circumuolutions, in which the meat maketh profitable stay and deliberation: this gut also giueth name to that fearefull disease called *Ileos*, or *Iliaca passio*. It is scituate vnder the Nauell, on both sides at the bones called *Ilea*, or hanch bones, and the cox or hip-bone: and though it be continuall with the *Jejunum*, and

and of a like substance, yet heerein it differs, that we finde it not either so empty of *Chylus*, or so full of Veines. It beginneth where the gut groweth reddish, and the Meferaicke Veines grow smailer and fewer, and passing vnder the right Kidney, meeteth with the crasse and large or great gut, that [Tab.⁶. Fig.¹: O] buncheth out like a great Globe or Bowle, and endeth in his left side where it hath two holes; one continued with the *Ileon*, another lower, to which the blinde gut is ioyned. [Tab.⁶. Fig.¹: 3, 3, N] It is the longest of all the guts, euen one and twenty palmes long, and as broad as a finger is thicke, and because this gut onely can fall into the cod, this onely causeth the rupture cald *Hernia intestinalis*, the gut rupture, and so much of the small guts.

Hernia intestinalis.

The great guts.
The blind gut called *Cecum* *Intestinum*.

The great guts begin [Tab.⁶. Fig.¹: 3, 3, O] where on the right side they strut out like a great Bowle, where there hangeth downe an Appendix or additament, which is the first of the thicke guts, and is called *τυφλόν* or *Cecum*, that is, the blinde gut [Tab.⁶. Fig.¹: 3, 3, P] ha- uing that name from his obscure vse, others call it *Monoculus*, because it hath but one per- foration, yet some say it hath two in the same superficies, but diuided by so fine and thin a distance, that it seemes but one: when notwithstanding one of them is the end of the *I- leon*, [Tab.⁶. Fig.¹: 3, 3, N] and the other the beginning of the blinde gut, or of the Appendix. It taketh his beginning which is very thicke, from two heads; the end of the *Ileon*, [Tab.⁶. Fig.¹: 3, 3, N & O] and the beginning of the Colon: vnlesse we had rather say, that the vtmost part of the Colon ends into it, and that the *Ileon* is continued with it where it begins. In a man it is a slender long Appendix, and like vnto a great writhen worme [Tab.⁶. Fig.¹: 3, 3, 3, 1] or a little purse narrow toward the bottome, whence also it is called *Saccus*, farre nar- rower and streightier then any of the other guts; foure Finger long, and as broad as the thumbe, and is knit to the right Kidney by the mediation of the *Peritonaeum*, but hath no Mesentery tyed vnto it. In Dogges it is farre greater, and besides differs in the originall, for in them it taketh his beginning rather from the beginning of the Colon on the right side of it, then on the left.

What was the *Cecum* of the Ancients.

The vse of the blinde gut of the Ancients.

Of the Ap- pendix.

The Ancients did not call this Appendix of the Colon the blind gut (whence some of them haue deliuered, that in Beasts there are three thicke guts, in a man but two) but for it, did take that Globous [Tab.⁶. Fig.¹: at O] extuberation, which passeth from the insertion of the small guts vnto the Colon, of which we spake euen now. Wherefore *Galen* placeth the blinde gut on the right side of the *Ileon*, but the Colon he saith ariseth out of the left side, brought first vpward by the right *Ilea* or flankes. This blinde gut of the Ancients which we call the beginning of the Colon, in Apes, Dogges, Swine, & Oxen is very great, in whom it is a good helpe that in their groueling gate, when their fore-parts are violently moued, the excrements do not recoil to the small guts. The vse of this blind Gut, saith *Galen*, (vn- derstanding the beginning and bowled extuberation of the Colon) is to be as a belly wher- in the excrements are receiued, that if in the passage any thing haue escaped the distribu- ting vertue of the small guts, and the Meferiack Veines, it might by remayning sometime in this blinde gut be exhausted and sucked out. But the vse of the Appendix is whilst the Infant is in the wombe, to receiue those many and liquid excrements which in many mo- neths time are gathered together. After the childe comes to any growth in the world, the vse of this Appendix ceaseth, because (proportionably considered) there are fewer ex- crements gathered in the Collicke gut, and those that are, are dryer & thicker. Wherefore one saith verie wel, that the excrements growing fewer, are not driuen thereinto, and so it remayneth contracted and gathered together, not in length, (for the length, continueth the same) but in the Latitude, ouer it was in the Infant, euen as we saide before, it hapneth in the vmbilicall vessels.

The Colon or Collick Gut.

The situati- on of it.

The second thicke gut, [Tab.⁶. Fig.¹: 1. and 3. from O to 2. Tab.⁵ from 1 to O, Tab.⁷ EEEE] is more lax and loose, and is called *κόλον* of a word which signifieth to fore-flow, because by reason of his many blowne and swelling Chambers or Cels [Tab.⁶ Fig.²: 3, 3, Y] it forsloweth the passage of the excrements; or of a word which signifieth to wreth, or to rack, because of the racking Collick paine which in it is bred. The beginning of this gut, called by the Ancients the blinde gut [Tab.⁶ Figur.¹: 2. O] as is saide, is very large and more capacious then any other part of the gut is, and round like a Bowle or Globe, seated in the right *Ile- um* or flanke, [Tab.⁵ from 1 to K.] for there is a fit place empty for it, because the right kid- ney hangeth hie, to which it cleaueth: and touching the bladder of Gall vnder the Luer, yea sometimes being fastned vnto it, that it is dyed yellow by it, is turned vpward, rouled ouerthwart vnder the bottome of the stomacke [Tab.⁵ from K to L] and so passeth ouer the small

small guts. And this is the reason why the Ancients haue written tha it occupyeth the vpper place, yet not in Dogges but in Men. And surely heerein Nature hath made an excellent prouision both for nourishment and concoction, because we eate many hard meates, which neither the stomacke nor the small guts are able sufficiently to put ouer, which are deteined in the Chambers of the Colon; and because this Colon passeth vnder the stomacke and the Liuer the fountaine of heate, these hard meates are there concocted and made fit for nourishment, and from hence are suckt away by the Meseraick veines. On the left side it is tyed to the Spleene [Tab. 5. G] with rare and thin Membranes; from the spleen it passeth vnto the share bone [Tab. 5. from L to M] and then is presently turned backward to the left Kidney, to which it is strongly bound, and so maketh a shew as it were of a Scythian bow. This strong binding of the Collicke gut to the left Kidney, is the cause why the Nephritick paine or fit of the stone in the Kidneys, is confounded with the collicke payne.

Table vi. sheweth the lesser and the greater guts.

The first figure sheweth the forme and folding passage of the lesser guts.

The second Figure sheweth the forme and convolutions of the greater guts, and the Muscles of the Fundament.

The thirde Figure sheweth together with the figure of the great gutties, the value or Membrane of the Colon or Collicke gut.

The fourth Figure sheweth a part of the collick and right guts, and the coates of the Guts.

L

But

The length
of the Collick
gut.

But to returne to the Collicke gut; at the left Kidney it is much narrower, lest it should compress the spleene; wherefore those men that haue swolne spleenes, doe not easily breake winde, vnlesse their spleenes be pressed; here also it hath no chambers: and againe arising more on the left side as it were vnto the seate of the Nauell [Table 6. Fig. 2. and 3. from S to T] maketh a double, (which double is the cause that in this place the Collicke torments are most grieuous, so that we haue seene heere apostemations [Table 5. M] matured or ripened through the skin, and after healed) and so being carried to the beginning of the *os sacrum*, in that very place where on the one side it arose from the right gut, it now on the other side [Tab. 5. N] endeth in it; but is distinguished from it by a certaine narrownesse, caused as it were by the whipping about [Table 6. Figure 2. from T to T] of a streight band: which place all Physitians in the administring of Clisters, and cure of the Collicke torments, must not forget. The length of this gut is about 7. palmes [demonstrated in the 6. Table and the 1. and 2. Figures] and so many fingers, and in breadth it is as wide as a mans Fist is thicke.

It is the largest and widest of all the Guts, that it might be a receptacle of the winds ingendered in the first concoction, to wit, in the stomacke and the small Guts; as also of the unprofitable and faeculent part of the *Chylus*, which remaineth about the end of the small Guts: lest (saith *Galen* in his fourth booke *de usu partium* and the 18 chapter) we should be constrained continually, or ouer often to empty our bodies, because within vs there is continuall segregation made of the excrements from the nourishment. Now this Gut being so capacious, those excrements may in great quantity be retained, and auoyded but at conuenient times.

The Celles also or chambers of this Gutte [Tab. 5. Q Q, Tab. 6. Fig. 2, 3, TT] make much for this purpose of Nature; and hence it is that some Birds whose guts haue no such Celles, doe continually mite, or very often: and therefore some haue called this collicke Gut, *The lower Belly*.

Lest therefore the excrements should forceably issue out, or perpetually prouoke the expulsive faculty, this Gut first of all ariseth vpwrd [Table 6. Fig. 2, and 3. from O to Q,] afterward bending downward, it is againe reflected vpwrd neere the end thereof [Tab. 6. Figure 2, and 3, from S to T] not vnlike to a *Romane S*. And hence it is that in our deiections, the excrements are not auoyded all at once, but as it were at two stooles, the second following the first, after a little distance of time.

And because it is very great, therefore it hath two strong ligaments; one, whereby it is fast tyed to the vpper parts, and by the other to the lower. It is also fastned to the backe by meanes of an externall membrane, springing out of the lower membrane of the Kall, as the other Guts are tyed to the backe by the interposition or helpe of the *Mesenterie*. But in Dogges it is no where tyed to the Kall, neither hath it any of these ligaments. If it were narrow as the small Guts, it would alwayes be distended, and so alwayes tortured.

Again, whereas the excrements when they passe out of the *Ileon* into the Collick gut, doe manifestly ascend [Tab. 6. Fig. 3, from N to O] lest in the compression of the belly (which is made by the muscles of the *Abdomen* and the helpe of the midriffe) to the sledge; the excrements and putrid or rotten vapours should not so easily finde the lower passage by the right gut, as returne out of the Colon into the *Ileon*, and so disturbe the distribution of the *Chylus*, and at length issue by the mouth, as it hapneth in that miserable disease called *Iliaca passio*, where the gut *Ileon* doubling into it selfe, maketh such a constipation of the belly, that the meate cannot descend, and so the remainders thereof being yet liquid in the small gut, and defiled with the noysome saueur of that place, are returned by vomit, and at last the excrements themselves, though not out of the great guts. But lest in euery notable compression of the belly this should happen, Nature hath ordained and scituated a certain valve, leaf-doore, or floud-gate, at the beginning [Tab. 6. Fig. 3, *] of this Colon where it is ioyned to the *Ileon*, which is membranous and thick, and looketh vpwrd, because the excrements of the meate are carried by ascent not by descent, out of the *Ileon* into the Colon, as is said before. This valve is easily found by the Anatomist, if you poure water into the right gut and hold it and the Colon vpwrd, for then you shall perceiue that none of the water, will passe into the *Ileon*, no nor winde, vnlesse you presse it very hard. You may finde it also when the guts are cleansed, but then it is somewhat vitiated by the transfusion of water, which you must necessarily vse in the cleansing of them.

The valves of
the Colon.

Lib. 5. method.
meden. cap. 48.

Hence it is that *Galen* sayth, the matter of clisters cannot naturally ascend into the *Ileon*

or

or small guts, although their medicinable force and vertue may goe a great deale higher. *Andreas Laurentius* hath described this valve in his Anatomie, where also he maketh mention of *Bauhines* description of it, and attributeth vnto it this vse especially of hindering the regurgitation of the excrements. But *Archangelus* sayeth, that at the blinde gut there are three valves like those in the heart, all appoynted for the same purpose, which the others before did agree vpon.

Lib. 13. metho.
medend. cap. 17

The substance of the Colon is more fleshy then that of the other guts, & beside it hath many Celles [Table 5. QQ, table 6. Figure 2, 3, Y] or chambered cavities, diuersly as it were arched; and againe linking into a narrower constraynt, wherein the hardest part of the meate may rest, and so receiue (for they lie vnder the stomacke and the Liuer [Table 5. at CC] a better concoction. But the small guts haue none of these Cels; the reason is, that the excrements of the Chylus should not be retained therein, the distribution of the same hindered, or the roome of the belly taken vp therewith. Finally, least the Cels or chambers of this Colon should bee dissolued or loosened foorth, there runneth through his middle and vpper part after his length, a certaine *vinculum* or band of the breadth of the middle finger: which being loosened or broken, those chambers are dissolued. When this Colon comes neare to the right gut, it becommeth round [table 6. Figure 2, 3, V] like the Colon in Dogges (that so the excrements and the winde also which issueth sometimes silently, sometimes with noyse, might bee more easily excluded) and so his end is narrow and straight, fit to ioine with the right gut.

The third of the great guts [Table 5, his beginning is at O vnder the bottom of the bladder, table 6. Figure 2, 3, Z, table 7, FG] is called *rectum*, of his right bore, and *dexter*, the beginner by *Hippocrates* in his first booke *Epidem.* because it hath his beginning where the boughts of the guts do end, and thence passeth from the top of the *sacrum* or holy bone, to the end of the rumpe, to which it is firmly tied by the interposition of [Table 6. Fig. 4. bb] the *Peritoneum*, least when it is burdened, it should fall with his owne waight: and so endeth in the seate, [Table 6. Fig. 2, 3, a] in men vnder [Table 6, vnder b] the bladder; in women vnder the wombe. In this place it is very great, which *Hippocrates* calleth *Partem laxam* or his loose part, and groweth to the yarde of men [Table 6, Figure 2, 3, d] sheweth the place] and to the necke of womens wombes, by the interposition of a musculous substance.

The last great
gut called *rectum*,
or the
right gut.

Hence comes in men that notable sympathy of this gut with the bladder, which maketh a man that is troubled with the stone in the bladder, to be euery moment prouoked to the stoole, but yet in women there is a greater sympathy betwene this gut and the wombe; so that oftentimes by compassion the gutte is vlceraed, and the excrements are auoyded by the secret parts. This gut could not be more commodiously placed; for the excrements being herein by degrees collected may be fitly together excluded. To the end of this gut a round muskle [Table 6. Figure 2, 3, a] is annexed, which may binde the orifice of it, whereupon it is called by *Hippocrates* & *Galen* *σφιγκτηρ*, that the excrements might not at all times but onely by voluntary compression and violence be euacuated. This gut is a palme and a halfe long [Table 6. Figure 2, 3, from z to a] and three fingers broad, and very corpulent or substantiall, and hath certaine fat appendixes or additaments growing to it without.

The great
sympathy be-
twene the
right gut and
the bladder.

The sphincter
muscle.

All these Guts as they are similar parts, do consist of a spermatieall substance and bloudy matter, changed into their proper flesh, if it may be so called: but as they are dissimilar they haue a membranous substance, that so they may without paine be distended or stretched, when they strut with the *Chylus*, with the excrements, or with winde; yet is not this membranous substance alike thicke, but the small guts haue it more slender, the great guts more crasse and thicke. This may bee shiuen into three coates; whereof one is common [Table 6. Figure 4, ee] to them all, as hauing his originall *mediately*, sayeth *Galen* 4. *usu partium* 17. from the *Peritoneum*: but immediately the *duodenum* and that part of the Colon that cleaueth to the stomacke, hath it from the lower membrane of the Kall, although it be not so in Dogs: and the *Ieiunum*, the *Ileon*, and the remainder beside of all the great Guts, haue their coate from the membranes of the *mesenterie*. For the membranes of the *mesenterie*, carrying the vesselles to the Guts, doe grow vnto them, where parting asunder, they feuerally walk along the sides of the Guts, & do degenerate into their third coat. This first common coat they haue as instead of a ligament, so also as a couering for their better defence. They haue beside two proper coats, [Tab. 6. Fig. 5. ff g] partly that their expelling power, saith *Galen*, might bee of greater force, partly also for security, when they abide

The 3 coates
of the guts.

4. vfu part. 17 many difficult affayes in diuers diseases, especially in the *Dysenteria* or bloody Flux, that the inmost beeing hurt, the other may remaine perfect for the performance of their duty. Wherefore, many haue beene knowne to superuiue when the inner coate hath beene eaten out: yet both these coats are thinner and softer then those of the stomacke, because this receyueth the meate when it is harder and vnconcocted, those when it is for the most part concocted and attenuated or made as thin as pulpe. The first [*Tab. 6. Fig. 4. ff*] or vter of these coates is membranous, but strong; for the most part furnished with tranuerse Fibres, sprinkled also with fleshy fibres, first to encrease his heate, that thereby the lesse laboured and digested parts of the Chylus may in their passage be more thoroughly concocted; and again, that like Muscles they might contract the guts to expel those final remainders which could not be auoyded by the compression of the *Abdomen*. Ouer this coate is drawne as it were a Veyle or Filme, thight but very fine, wouen for the most part of right Fibres. The other proper [*Tab. 6. Fig. 4. g*] coate is on the inside; in the small guts rugous or plightie, (in the Colon the plights are vnfolded and spread abroad into Cels) that it might moderately stay the Chylus as it falleth downward, thar if any part of it bee lesse laboured, it might receiue a farther degree of concoction in the passage.

The crust of the guts which is first lost in bloody fluxes.

Moreouer, that the same *Chylus* might the better bee sucked vp by the Veynes, these tranuerse foulds make this coate longer, and in some doubly and trebly longer then the vter coate: and for this cause also it was necessarily gathered into Plights; and these foulds or surphles are moueable, & may be driuen out of one place into another, (as the surphles of a hemme gathered vpon a threed) that they may retaine the *Chylus* moderately and without violence. This coate is also neruous, but yet it appears more fleshy, because of a crust like a Membrane which compasseth it about, engendred of the proper excrements of the guts arising from the third concoction, least the mouth of the Meseraicke Veins opening into this inner coate, should be stopped; and least the same inner coate, or the mouths of the Veines should be made callous or hard by the perpetuall passing of the *Chylus*. Both these proper coats at the end of the Colon and in the right gut are thicker and thighter or faster.

What fibres euerie coate hath.

They haue Fibres of all kindes, the inner oblique or slope Fibres, that they may reteine, the middle tranuerse or ouerthwart that they may expell, to the outward are added a few right Fibres, least the tranuerse should be separated asunder: wherefore without the gut they are tyed together with the right fibres as it were with a ligament, euen as Chirugions for the holding on of circular or round Ties, do cast ouer them right bands. But the right Fibres are fewer in the small guts, more in the great. In the Colon the Fibres follow his impressions or chambers. They are very great and large in the right gut, because of the many and hard excrements there heaped together.

4. The vessel of the guts.

The vessels of the guts (exhibited in the third *Table*) are Veines from the port veine, arteries from the Coeliacall [*Tab. 4*] and Mesentericall branches. For, to the *Duodenum* & the beginning of the *Ieiunum*, the gut-veine called *Intestinalis* runneth with a long course; but the rest of the *Ieiunum* and the *Ileon* and a part of the Colon, from the *Ileon* to the left kidney, haue Meseraicke [*Tab. 4. Fig. 2. 000*] veynes, which are carryed from aboue with an oblique passage through both the coars of the Mesentery, as it were out of his center. The vse of their veines, is to carry the Chylus from the guts to the Liuer, & bring back blood to them for their nourishment: the vse of their Arteries, is that they might be cherished with vitall blood, and by their perpetuall motion be preserved from corruption and putrefaction. *Galen* thought, that they tooke vp also a little of the meate in their passage. To the other and remaining part of the Colon and to the right gut, they are in a right line carried from the left Mesentericall Veine and the inferiour Mesentericall Artery.

4. vfu part. 17

They haue Nerues from the sixt paire, the *Duodenum* very small ones from those stomacke sinnewes which compass the *Pylorus* or lower mouth of the stomacke: the rest of the guts on both sides, receiue infinite surcles from a braunch which proceedeth from the roots of the ribs, from whence they haue most acute sense, that they might apprehend the prouocation of the chollier and the excrements; notwithstanding that a certaine mucous or slimy matter which lineth them within, makes their sensation somewhat more dull.

The vse of the fat and slime in the guts.

On the outside they are smeared, sometimes couered with fat, and on the inside lined with slime, and as it were nealed like earthen pots, that through their slipperinesse the excrements of the belly might sooner be precipitated or thrust downe (some thinke the Colon is lined within with fat) and least their exquisite sense should bee continually prouoked.

The

The common vse of the guts is to be in stead of earth or soyle to yeelde nourishment to the parts. For as in the earth is contained the aliment of the plants which they draw out by the Fibres or strings of the roots, so in the guts is the *Chylus*, which the rootes of the Meseraick veines do sucke out for the nourishment of the creature. Againe, the vse of the small guts is to be the Instrument of distributing the aliment; so saith *Galen* in his 4. Booke *de Vsu partium*, the 8. and the 18. chapters. For it behooued that there should be one Organ to concoct, and another to distribute; for otherwise the veines could not but haue drawn crude together with concocted and laboured nourishment. For the *Chylus* boyled in the stomacke was to be distributed to other parts, and the profitable parts thereof to be segregated & separated, which is accomplished by the Meseraicall veines. But because, as it hapneth in a Viall full of water, if it be turned vp the water cannot issue at the necke but by drops and degrees; so in the guts, if the veines had beene set to one place, the multitude of the *Chylus* would haue stopped his owne passage: therefore Nature hath well provided, that the guts should be drawn out into a great length, that so in each part of them a little quantity might be contained, & so a conuenient proportion suckt away by the mouths of the veines. Moreover, in the very passage of the *Chylus* along the guts, it receiueth a farther degree of concoction, as also doth the blood in all the veines. And therefore the substance of the guts is not much vnlike that of the stomack. But because they are not so neere the heate of the liuer as is the stomack, therefore nature hath assisted their cold membranous substance, by couering the with the warme happing of the *Omentum* or Kel, wherby their weak heat is cherished.

The common vse of the guts.

The vse of the small guts.

The vse of the great guts is to contain the thicke excrements and remainders of the meat together with the choler deriued vnto them from the liuer by the passage of gall, as also the winds that are daily gathered, which are stored in the chambers of the *Colon*, and the bredth of the other great guttes, and kept in by the Muscles of the fundament, as we shall more manifestly shew afterward.

The vse of the great Guts.

CHAP. VI. Of the Mesentery.

IT is called *Mesenterium* and *μεσεντερον* in Greek, because it is placed in the middle of the guts, which as we said before, are called *εσπερα*, for his feate is in the midst betwene the guts toward their backward position [Tab. 7. Fig. 1.] and incircleth them round. It is called also *μεσενταριον* from his peculiar substance. His figure is circular [Tab. 7. Fig. 1, 2.] and plaine, but gathered into folds; about the beginning it is narrow, in the middle ample and large, and in the sides (especially the left side where it descendeth to the right gut) it becommeth more long, for which causes *Galen* said, it was treble or three-fold.

The scituation cause of the name.

His Figure.

His beginning is at the first and third Spondell or racke bone of the Loynes from the *Peritoneum*, from whence are produced membranous Fibres which spend themselves in the two Membranes [Tab. 7. Fig. 2. TR] of the Mesenterie, hence it is that there is great consent betwene the Loynes and the guts; beside there passe also from thence certaine Nerues vnto the Mesentery. For it is compounded of Membranes, Nerues, Veines, Arteries, Glandules and Fat.

Originall.

It hath two Membranes [Tab. 7. Fig. 2. TR] one lying vpon another (in Dogges where it admitteth no vessels, they so grow together as if it were but of one simple Membrane, neither hath it any fat to make separation) and those firme and strong, as well for the strengthening of the vessels which are manifold and passe together vnto the guts, (to which vessels it serueth for a band and strong muniment) as also lest in violent motions the position of the guts should be altered or confounded, and that they might be stronglier tyed to the backe.

His Membranes.

The Meseraicke Veines [table 3. add table 7. Fig. 2.] diffused or spread abroad thorough these Membranes are innumerable and wondrous small, as it were the fine slender threds of the roots of a tree, which are still gathered into greater, till they growe all into one entire roote; so these vessels by little and little are knit together into greater, and those greater into others yet greater, till they are all vnited into one veine, which passeth vnto the Port, and resteth in the hollow side of the Liuer. Two Arteries called the vpper and lower *Mesentericall*, are sent vnto the guts, and make the Meseraicke Arteries, which also run through the Mesentery, that by their continuall motion they might ventilate and with

The scituation cause of the name.

The first Figure sheweth where the Mesentery beginneth or ariseth, his scite, connexion, and vessels; in it also the guts are remooved from the middle of the Belly, and are laide upward and downward vnto the sides, that the Mesentery might better appeare.

The second Figure sheweth the Mesentery taken and freed from the body.

vitall spirite illustrate the Mesentery and guts, and so keepe them from corrupting; al which also are ioyned into one great one which lyeth vpon the backe. This Galen obserued sometimes to be presently parted in twaine out of one roote, sometimes to bee two seuerall distinct instantly from their beginning.

Nerves.

It hath Nerves also sprinkled diuersly as it were into many tendrils. Those are two, one on either side from the nerves which are reached from the six paire to the roots of the ribs: which Nerves being spread abroad after the fashion of a Membrane, doe inuest the branches of the Arteries, by which meanes the colde Nerves by the touch and society of the Arteries becomming warme, the Animall vertue proceeding from the Brain, is more freely communicated to the guts. It hath Nerves also from the sinewes proceeding from the Spondels of the loynes, and that for his better sense, that feeling those things that molest it, the expelling vertue being prouoked, it might turne them downe into the Guts. These Nerves together with the Veines and Arteries, are receiued into the center [tab. 7. Figure 1, 2. H] of the Mesentery, diffused through the whole body of it, and with an innumerable off-spring are carried through his coates or Membranes vnto the guts. It hath also glandules or kernels very [Tab. 7. Fig. 1, 2. KK] many (to which certaine thredy or hairy veines do come from the Meseraickes) interlaced with infinite diuarcations of the branches of the Port-veine, & the great Artery, with which they hold a certain proportion for their magnitude; but the biggest of them are about his center, where the first distribution of the vessels is made, and where they are most gathered together: as wel that they may support & diuide the vessels, as also that they may hinder their compression which would otherwise foreslow the

The Glandules
of the Mesen-
terry.

the distribution of the *Chylus*, like as they doe when they become *schirrus* [Tab. 7, Figure 1. 2, 11] or hard; whence followeth for this reason a generall consumption of the whole body.

Beside, it had not beene safe that so many vessels riding so high, being so slender and running so long course from their originall, should bee carried to the trunk of the port-veine without a kinde of conuoy: wherefore these glandules or kernels, as it were certaine wedges, are set between their diuisions, that in vehement motions they be not broken nor offende one against another. Finally they serue to moysten the guts, that their concoction may be celebrated by elixation or boyling, that is, by heate and moysture.

Amongst these glandules there is plenty of Fat, made of blood sweating or falling out of those vessels wee spake of euen now, and there retayned by the solidity of the membranes, with which fat the middle spaces are filled, and the heate of the parts cherished, that so the *Chylus* which is carried through them, is better prepared for sanguification.

And although this *Mesenterie* be one and continued together, yet in regard of his double originall, and of the guts which it tyeth together, and of the two Arteries; it may be diuided into that *Mesenterie* which knitteth together the small guts [Table 7. Fig. 2, L MM] in the middest of the belly called *μασάριον* and inio that which tyeth the colon [Tab. 7. Figure 2, from N to O] both on the right side and the left; [Tab. 7. Fig. 2, from P to Q] (not vnder the bottom of the stomach, for to that it is knit by the helpe of the *Omentum*) [Tab. 7. Fig. 2, from O to P] and in his lower part [Tab. 7. Fig. 2, from Q to R] groweth to the right Gut and is called by *Hippocrates* *μεσόκολον*. Lastly, it hath a part which they call the appendix [Tab. 7. Fig. 2, from Q to R] of the *Mesenterie*, being of the nature of a ligament, whereupon *Galen* diuideth it into the right, the left, and the middle *mesenterie*.

The vse of the *Mesenterie* is to tie the Guts together, as it were by a common ligament, and to fasten them to the Racke-bones of the Loynes, that they neither should bee confusedly shuffled together, or fall downe by reason of their waight. But the Colon or collick Gut in that part of it that runneth vnder the stomacke, is tyed to the backe by the Kell as hath beene sayde. Againe, the double membrane of this *mesenterie* doth inclose and sustaine the vessels which runne through it, that they should not be medled together, and so hinder one another, as also that they might more safely attaine vnto the Guttles, whereas happely if they were not strengthened by this duplication, they might break when a man did leape or fall, or otherwise straine his body there about.

CHAP. VII.

Of the Pancreas or sweet-bread.

Pancreas, that is, all flesh, is so called because of the likenesse it hath with flesh in an ordinary and moderate body, for in a Fat body it seemeth to be Fat it selfe: it is also called *παλινκρεας*. It is an vnshapely body, very loose, all glandulous (wherefore *Archangelus* would haue it called *Pandenon*) and large. It hath his beginning at the first spondle of the loynes, and thence defused, spreads it selfe vnder the back-part of the stomach and his bottome, vnder the *duodenum* also [as appareth in the Table belonging to the chapter of the bladder of gall at the note 1] and the gate-veine at the Kidneyes, euen as farre as the seates of the Liuer and the spleene. In man it is not so red as in Dogges, and in all beasts because of their groueling gate, it lyeth vpon the stomacke.

That which in his middle appeareth white, is his *Parenchyma* or proper flesh, and because of his whitenes & softnesse, some call it *Lactes*: we call it the sweet-bread, because in Swine it is esteemed a sweete morsell, though the sweet bread of a Calfe or Veale bee another thing, as you shall heare hereafter. It hath veines but very small from the Gate-veines for his nourishment: and Arteries from the *Calicall* for his life; sinewes also from the sixt paire, & glandules. The especiall vse of it is to sustaine, secure & preferue from Compression the diuisions of the branches of the Gate-veine, of the *Calicall* Arterie, and of the nerues which are carried to the stomach, and to the Gut called *duodenum*; but especially, the Splenick braunch which passeth vnto the spleene: as also the vessell which containeth the choller called *Porus Biliaris*, because about his seate is the originall of all their diuisions.

Moreouer another vse it hath, by reason of the many glandules in it containd, which is to licke vp the remaynders of that muddy and superfluous Fat (or if you will, the crude

The sweet-
bread.

The situati-
on of it.

His vessels and
glandules.

His vse.

The vse of his
Glandules.

and

and phlegmaticke part of the blood, which *Hippocrates* calleth *hCanoſam humiditatem*, the muddy moyſture) which the Kall and Meſenterie could not contayne: that the blood being thus depured, might bee exhibited to the inward parts, more pure and better defecated.

Againe, whereas theſe glandules doe as it were feede vpon and deuoure the crude or raw and moyſt part of the blood; it muſt needs follow that from them ſhould exhale infinite vapours moyſt and hot, which ſteaming vp round about the ſtomacke, doe make this action of *Chyliſication*, a kinde of elixation or ſtewing, like a Maryes Bath.

nother vſe
of the pancreas

Finally, the *Pancreas* like a pillow or quiſhion is placed vnder the ſtomacke and other parts, leaſt being filled, they ſhould leane too hard vpon the ſpondelles of the loynes, and be violated with their hardneſſe. Albeit *Fallopius* and *Archangelus* I know doe reiect this vſe of it, becauſe there is no ſuch vſe of it in brute beaſtes, in whome it lyeth about the ſtomacke. It parteth alſo the ſtomacke from the great Arterie, leaſt when the ſtomacke is very full and ſtrutteth out, the Arterie ſhould be preſſed, and ſo the free courſe of the vitall ſpirits to the lower parts intercepted.

CHAP. VIII.

Of the branches of the Hollow Veine, & the great Arterie, diſſeminated through the lower Belly.

WEE ſhould now proceede vnto the ſtomacke, ſauing that wee thinke it not amiſſe before wee come vnto it, to giue you a ſhort view of the diuarcations of the hollow veine and the great artery, as they diuide and ſubdiuide themſelues in the lower belly: that if you pleaſe in the ſame body, you may call for a ſight of them before you trouble the carcaſſe too much, by remoouing the ſtomack and other entrals. And firſt of the branches of the Hollow veine.

The Hollow veine hath two trunke, one paſſeth vpward through the midriffe, the other downward, which we will diuide into the trunk and the branches. From the trunk [Table 8. K] moſt commonly there proceed on each ſide foure veines.

Adipoſa.

The firſt is called *Adipoſa*, or the veine of the Fat of the Kidneyes: the left of theſe, [tab. 8.g] is for the moſt part higher then the right [table 8.f.] They runne vnto the Fat of the Kidneyes and their vtter membrane. Sometimes one of them ariſeth from the Emulgent, as appeareth, [table 8.f.] ſometimes both.

Emulgent.

The ſecond is the Emulgent; the left of theſe [Tab. 8.c] which ſometimes ariſeth threefold, is higher then the right [Table 8.d] leaſt one of them ſhould hinder another in their ſuction; and longer alſo, becauſe the ſeminarie or ſeede veſſell ſpringeth out of it [Tab. 8.i.] Both of them when they attaine vnto the middeſt of the body of the Kidneyes are diuided and ſo implanted to carry vnto them the whey of the blood, which becauſe it ſhould not returne againe into the hollow veine, Nature hath placed certaine valves in the emulgents.

Spermarica.

The third is called *Spermarica* or the ſeede veine; the right of theſe [Table 8.b] is ſometimes double, ariſing out of the middle of the trunk below the Emulgent: The left ariſeth from the Emulgent [Tab. 8.i] becauſe otherwiſe it muſt haue rid ouer the Arterie, yet notwithstanding ſometimes it receiueth a ſmall branch from the *Caua* or hollow veine. They deſcend obliquely to the teſticles, and determine in the Bodden body called *Corpus varicoſum*, to which they carry the matter of the ſeede.

Lumbares.

The fourth are called *Lumbares* or the veines of the Loynes. Theſe are ſometimes two, ſometimes three on a ſide [Tab. 8.mmm] they paſſe between foure rack-bones of the loynes, and doe ſend two veines to the ſides of the marrow of the back which ariſe vnto the Braine, and haply they bring from the braine a part of the matter of the ſeede.

Rami Iliaci.

Afterward at the fourth ſpondell of the loynes, the trunk of the hollow veine [Table 8.n] is diuided into two branches which are called *Rami Iliaci*, out of which before their diuiſion there proceede on either ſide two veines.

Muſcula.

The firſt is called *Muſcula* [Table 8.np, np] one of which is higher then the other; ſometimes it proceedeth not from the branches, but from the trunk, and paſſeth to the muſcles of the loynes and of the *abdomen* or paunch, from whence it hath his name.

Sacra.

The ſecond is called *sacra*, a ſmall veine, ſometimes ſingle, ſometimes double, and paſſeth through the vppermoſt and formeſt holes of the *os ſacrum* or holy-bone [Table 8.oo] vnto his marrow, and hath his name from the bone.

Then

The branches of the Hollow veine and the Great Arterie, disseminated through the lower Belly.

TABVLA VIII.

- AAA The midriffe called *septum transversum*.
 BG The Gibbous part of the Liuer, the right side at B, the left at G.
 CC The hollow part of the Liuer called *Cava recora*.
 D The bladder of gall.
 EF The foreside of both the Kidneys.
 H The Ligament which tieth the Liuer to the midriffe.
 I The umbilicall or Naucl-veine where it is inserted into the Liuer.
 K The trunk of the hollow veine called *Vena cava*.
 L The trunk of the great arterie.
 N The gullet where it passeth through the midriffe or the bofome of the Liuer called *sinus hepatis*.
 a The trunk of the Gate-veine.
 b The Cysticke veines where they goe to the bladder of gall.
 c The passage of the bladder of gall which goeth to the gut called *duodenum*.
 de The emulgent veines with the emulgent arteries vnder them.
 f The right fatty veine called *adiposa dextra*, arising out of the emulgent.
 g The left fatty veine arising out of the trunk of the hollow veine.
 h The spermaticall veines, the right arising out of the hollow veine, the left out of the left emulgent.
 i The 2. vnters which carry the vrine vnto the bladder.
 m m m The veines and arteries of the Loynes called *Lumbares*.
 n n n Below, the vpper muscle veine and arterie, called *muscula superiores*.
 o The diuision of the hollow veine about the holy bone.
 p p The holy veines and arteries called *sacra*.
 q The Iliacal branch of the hollow veine.
 r The Iliacal arterie.
 s The diuision of the Iliacal arterie, and the Iliacal veine vnder it, into the inward and the outward; the inward is marked with p, the outward with s.
 t The interior transverse or crosse branch.
 u u u The middle muscle veine.
 v v The veine and arterie of the yarde, proceeding from the branch marked with p, and s.
 w w The Hypogastricke veine which sendeth branches from the inner bough to the bladder, the wombe, and almost all the parts in the water-course.
 x x The place where the umbilicall arteries are inserted.
 y A portion of the externall branch, wherewith the internall is augmented, Character. The remainder of the inward branch. z, z The Epigastricke veine which is a propagation of the vtter bough: it creepeth vpward by the lower parts of the Abdomen to the Nauell. 2 The lower muscle veine, reaching to the Coxendix or Hips: a veine without an arterie, which derieth his branches to the muscle of the fundament, and to the skin about them. 4 The great arterie piercing the midriffe. 5 The arterie of the midriffe called *Arteria phrenica*. 6 The Celiacal arterie. 7, 9 An arterie passing to the Liuer. 8 The Cysticke arterie, or arterie of the bladder or gall. 10 The vpper mesentericall arterie. 11 The originall of the spermaticall arteries. 12 The lower mesentericall arterie. 13 The coniunction of the spermaticall veine and arterie. 14 The diuision of the great arterie into the Iliacal branches, and how it ascendeth about the hollow veine. 15 The arterie of the priuities called *arteria pudenda*, which is a shoot of the inmost branch, going to the parts of generation. 16, 17 The remainder of both the trunks marked with p, and s, running to the thighs.

Then the Iliacal branch is on both sides bifurcated or forked [Tab. 8. vnder r] into an exterior or vter [tab. 8. vnder q] and an interior or inner. From these proceed three veines.

The first is called Epigastrica [Tab. 8. vnder character 1,] which is disseminated into the Peritoneum and the muscles of the abdomen. The chiefe branch of this veine ariseth vnder the right muscles of the Abdomen, euen vnto the veine called Mammeria, and with it about the Nauell is ioyned by Anastomosis or inoculation.

The second is called Hypogastrica, a notable veine [Tab. 8. uu] and sometimes double. It is disseminated almost into all parts of the Hypogastrium or water-course, the bladder the yarde and the wombe; and at the right gut maketh the externall Hemorrhoidall veines.

The third is called Pudenda [tab. 8. character 15 15] which is consumed into the scrotum & the flesh of the yarde or virile member.

These veines being thus deriued out of the Iliacal branches of the hollow veine, they passe on either side out of the lower belly [tab. 8. s t] and are called Crurales, or the veins of the thighs, of which we shall speake hereafter. And thus much of the branches of the Hollow veine, now followeth the great Arterie.

The Great Arterie also hath two Trunkes, the lesser goeth vpward, the greater [Tab. 8. character 4] descendeth, because it hath more parts to bee communicated vnto. This trunk

The bifurcation of the Iliacal veines. Epigastrica.

Hypogastrica.

Pudenda.

Crurales.

The greater trunk of the great Arterie.

accompanies the Hollow Veine (for the Veines and Arteries are sorted together quite through the body) and sendeth forth branches almost like vnto it, of which wee will now entreate.

Celiaca. The first is called *Celiaca* [Tab. 8. char. 6.] a notable artery of which we haue spoken before in the fourth Chapter.

Mesenterica Superiour. The second is called *Mesenterica superior* [Table 8. character 10] before Chapter 4. described.

Emulgens. The third is called *Emulgens* [Table 8. de] which together with the Emulgent Veines enter into the Kidneyes.

Spermatice. The fourth is called *Spermatice*, the right and the left [Tab. 8. char. 11] both of them arise from the trunk of the great artery, and together with the Spermaticall veines attaine vnto the Testicles, passing through the productions of the *Peritoneum* or rim of the belly.

Mesenterica Inferiour. The fift is called *Mesenterica inferior* [Table 8. char. 12] described in the 4. chapter.

Lumbares. The sixt are called *Lumbares*. [Tab. 8. at the upper mmm] They passe through the holes of the Spondels of the Loynes, not onely into the *Peritoneum* and the Muscles confining, but also send two Arteries to the marrow of the backe, which together with the veines aboue named, do ascend vnto the braine.

Iliaca, why it rideth aboue the hollowe veine. The seuenth is called *Iliaca*, which before the Artery is diuided, rideth ouer the hollow veine [Tab. 8. char. 14] lest if it should haue couched vpon the bone, it might haue beene hurt in his perpetuall motion.

Rami Iliaci. Afterward, as the hollow veine, so this great artery is diuided into two trunks, called *Rami Iliaci*, each of which parteth into an exteriour or outward, & an interiour or inward branch; [Tab. 8. at r q] the outward is the larger, and runneth into the thigh. From these before they come vnto the thigh proceede six branches.

Sacra. The first is called *sacra*, arising vnder the bifurcation or forking, [Tab. 8. o o] and passeth to the *Os sacrum* or Holy bone and his Marrowe, as the veines did called before *Sacra*. These are but small Arteries.

Muscula. The second is called *Muscula* [Table 8 ff] a branch of the vtter bough running vnto the neighbouring Muscles.

Hypogastrica. The third is called *Hypogastrica*, [Tab. 8. uu] branches of the inner bough passing vnto the bladder, the yarde, the wombe and the Muscles which couer the share bone.

Arteria Umbilicales. The fourth are called *Arteria umbilicales*, of which we haue spoke abundantly before.

Epigastrica. The fift is called *Epigastrica* [tab. 8. char. 1] a branch of the inner bough, which climbeth vp vnto the right Muscles of the *Abdomen*, and is ioyned with the *Mammaria*, as is saide of the Veines.

Pudenda. The sixt and last is called *Pudenda* [tab. 8 char. 15] a branch of the vtter bough, which is consumed in the skin of the virile member. That which remaineth of the great Arterie, passeth into the Thigh, and is called *Cruralis* of which wee shall entreate afterward: now we will returne vnto the Entrals or Bowels, from which we haue a little digressed, to shew you the diuications of these vessels in the Lower belly, but that very breesely, because we reserue their more exact description to their proper place in the Booke of the Veines and Arteries.

CHAP. IX.

Of the Stomacke.

The stomacks names.

THe Ventricle as it were a little Venter, is called in Greeke *nomia*, that is, a cauity or hollownesse, of a word that signifieth hollow or *concauous*, and *γαστήρ*, which is indeed the proper Greek word for it. It is the comon receptacle of meate & drink, the Kitchen of the body. It is but one in men & other creaturs that haue both iaws set with Teeth, but in those that chew the cud, which haue but one iaw of teeth, it is four-fold: in birds it is three fold. It was necessarily to be placed where his extention might not be hindered, yet as neere the mouth as might be for the receiuing of the meat to be coqued for the whol body. Wherefore for that there was no roome in the chest or neere the mouth, it being taken vp by the parts which serue for respiration, & encompassed beside with a wal of bone, which would haue hindred his dilatation, it is seated lower, [tab. 9. FF] immediatly vnder the

the *Diaphragma*: betweene the Liuer and the Spleene, [table 9. CC. sheweth the Liuer, G. the Spleene, and FF the stomacke] in the middest of the body, saith *Galen 4. vñ partium 7.* especially his vpper orifice, ouerthwart between the two *Hypochondria*, that it might be continued with the guts, not so much for the distribution of the *Chylus*, as that the Excrements might be more easily setled lower, least with their noysome vapours they should molest the heart and the Brain. It lyeth for the most part of it in the left *Hypochondrium*, as appeareth in the 9 Table, because heere it had most roome, and againe for the more commodious implantation of the vpper mouth, by which it receiue the meate; moreover, to giue way vnto the [table 9, CC] Liuer which takes vp the right side; and lastly, with the Spleene to helpe to ballance the body against the Liuer. Before, it lyeth bare, especiallie when it strutteth, not vnproperly then called *ἀποζωογασίς venter fermentatus*; (for when it is empty, it is more hid vnder the Liuer) that it may easily be felt with the hand; wherefore.

Tab. 9. sheweth the Bowels of the Lower belly, euerie one in their owne place. The ends of the lower Ribs, together with the Midriffe and the Peritonaeum adhering thereto are turned back, that the Liuer, the Spleene, and the stomacke might be better scene.

TABVLA. IX.

CC. The *Gibbous* or bunching part of the Liuer.

FF. The stomacke filled full of meate.

G. A part of the Spleene.

H. The blinde gut of the late writers: for the ancients tooke the top of the Colon for it.

K. to L. the same Collicke Gut lyeth vnder the whole bottome of the stomacke, which is the reason that those which are troubled with the Collicke cast so much.

L. to M. The passage of the Colon, from the spleene vnto the share bone by the left kidney a-way, which maketh the payne of the Stone and the Collicke on the lefte side, very harde to distinguish.

P. The sunken or fallen side of the Colon at P. and his Chambers and pusses at Q.

it is quickly affected with cold, and therefore care must be taken of it. On the right side, the vpper and forepart of it lyeth vnder the hollownesse [table 9. F vnder C] of the Liuer, & by it is embraced, whereby his heate is cherished. On the left side his greatest part reacheth to the *Diaphragma*, whereupon when it is too much stuffed, by hindering the motion of the *Diaphragma*, it causeth the disease calleth *Dyspnœa*: likewise the Spleene, [table 9 G] lieth vnder his left side against the backe and lower part thereof. Behind it are, the backbone as a strong and thicke defence, and the Muscles of the Loynes as a soft bed with fat growing thereto for his better repose, which also doe adde warmth vnto it. Below, it confineth vpon the guts and the *Omentum* or Kall, and vnder his bottome lyeth the Colon [table 9. KL] with the *Omentum* betweene them, whence commeth their mutuall consent and sympathy not onely in the Collicke paine, but also after the taking of a Medicine there followeth a kinde of loathing and vomiting, the excrements going this way to the *Rectum* or streight gut.

His

- His magnitude** His magnitude is diuers, *Hippocrates* counts it five palmes bigge. Taken out and blown it is much greater then it can be whilst it is in the body; notwithstanding, whether it containe more or lesse, yet it so closely embraceth that it receyue for the better concocting and boyling of it, that it leaueth no emptinesse in his whole cavity.
- The connectio.** But least being filled it should fall downe with the waight, his left orifice which is continued with the [Table 10. Figure 1, 2. G] *oesophagus* or Gullet, is tyed to the *Diaphragma*, the right is ioyned [Tab. 10. Fig. 1, 2. H with P] to the *Duodenum*. On his backe and vpper part, he lyeth vpon the backe bone, and cleaueth to the fift spondell of the Loynes; below to the *Omentum*, other where it is loose and free, that it might more freely be distended. Finally, vnder his bottome, and especially vnder his lower mouth called *Pylorus* [Ta. 10 Fig. 2. HP] and vnder the beginning of the *duodenum* is the *Pancreas* placed [Table 10. Figure 2. S] to bolster them vp. His figure [Table 10.] is round for the more capacity, and that it might be lesse subiect to be offended. Long it is because of his two orifices, which make it very like vnto a Bag-pipe. On the left side, and in the bottome [Table 10. Figure 2. M] it is larger and rounder, but toward the right hand it is by little and little attenuated or lessened, that it might giue place to the Liuer, and that the meate might by degrees fall from that side toward the bottome, which is the chiefe place of concoction. Foreward it is [Table 10. Figure 1. LL] equally bunched; backward [Table 10. Figure 2. MNO] whilst it is yet in the body it hath two protuberations or bunches, the left is the greater, the right is the lesse and flatter, betwixt which is a hollownesse which doeth not appeare when it is taken out and blowne: which hollownesse was ordayned to giue way to the spondels of the backe, [Table 10. Figure 2, O] and to the descending trunks of the hollow veine and the greate Arterie.
- His Cautie.** On the outside it is smooth, plaine and white: within [Table 10 Figure 4.] when it is knit or gathered together, it is rugous or rugged (as we see in Tripes) and reddish. It is hollow, and his hollownesse of all other parts the most ample, that it might receiue sufficient quantity of meate and drinke, least for our nourishment we should be constrained to bee alwayes eating; now, when it is once full or satisfied, wee may haue leysure for other businesse, whilst all the meate taken at a meale, be digested and distributed.
- His Orifices.** There are two Orifices in the vppermost region of it. On [Table 10. Figure 1. L] the left side one which appeareth best when the stomacke is best stuffed. This orifice is continued with the *oesophagus* or Gullet, [table 10, Fig. 1, 2, ABC] and about the eleauenth Spondel of the breast, is knit vnto the *Diaphragma* or Midriffe. It is also farre greater then the other, [table 10. Fig. 4. l in respect of m] of the same width with the *oesophagus*, that nothing which we can swallow might stay at it. Thicker also it is then the other, least it should be violated when it is constrained to receyue hard, thicke, and vnchewed gobbets, such as hunger bitten folke do with great raueness swallow downe and deuoure. It hath fleshy and circular Fibres [table 10. Fig. 4. l] that it might naturally streighten it selfe when it hath receiued the meate and drink, to intercept the ascent of vapors into the Brain, which some also would haue to giue great furtherance to the perfection of concoction, because those that would sodainly boyle any thing, do closely couer the pots mouth, that the vapours or fumes might be kept in. Againe, least the vapours flying vp to the heart or braine (which happeneth to great eaters, and those that are of a verie moist distemper) should cause the Giddinesse, the Meigram, suffusion, and a stinking or distastfull breath. This Orifice in some vpon extreame greefe is so contracted or drawne together, that they cannot swallow any whole meate.
- The vpper and left Orifice.** Finally, these Fibres serue to this good purpose, that those things which we eate, should not returne into the *oesophagus* or mouth when a man stoopeth low forward, or lieth much backward.
- A pretty note why in great griefe meat will not downe** This Orifice because of the abundance of sinnewes [tab. 10 Fig. 1, 2. TVE Fig. 2 XY] that it receyue, is of most exquisite sence, that it might feele it owne want; which sence of want stirreth vp the appetite, that the creature might addresse himselfe to provide for more meate and drinke to satisfie it. The Auncients call this Orifice *καρδία*, that is, the heart, because when it is affected, by reason of his exquisite sence, the like symptoms or accidents follow which follow them whose very hearts are affected, whence the paine of this mouth of the stomacke is called *Cardialgia*, we call it heart-burning, when indeed it is only a disease of the mouth of the stomacke. Sometimes the like soundings do follow as when the heart is affected; and to say truth, the heart is alwayes with it drawn into consent, not
- The seat of appetite.**
- καρδία or the heart-burning.**

so much because of the neere neighbourhood that is betweene them, as because their fi-
newes proceede from the same branch. Some call it the mouth of the stomach, common-
ly the vpper orifice; sometimes it is called the stomach, because of his largenesse; and be-
cause it commeth nearer to the back-bone then to the brest blade, therefore wee applie in
his diseases, locall medicines both behinde and before; before is more vsuall, but when
the stomacke laboureth, then we apply not onely before.

The neather and the right orifice [tab. 10. fig. 1. 2. H] of the stomache, is also bent a little
vpward, being the bredth as it were of foure fingers distant from the bottome, least the
weight of the meate should open it. This within, beside transuerse Fibres, is compassed
with a thicke and compacted circle, after the fashion of a round Muscle, or like the Sphin-
cter or Muscle of the sledge (which sometime becommeth *schirrhus* or hard) by which
after a naturall instinct, it may be shut and opened, streightned or widened. This remay-
neth fast locked till the meate bee perfectly changed and boyled into a moist and liquid
Creame, wherefore also it is narrower [tab. x. fig. 4. compare with m] then the left ori-
fice, yet it may be opened as wide, as do testifie the stones of fruite being eaten, Bullets of
Lead swallowed, and other things by chance gotten downe, which without annoyance
are againe rendred at the sledge. This afterward beeing by degrees relaxed and opened,
doth by his strength, not being prouoked by weight, driue down the Chylus into the *duo-*
denum [tab. x. fig. 1. 2. P] and so to the rest of the guttes, to bee sucked by the Meseraicke
Veines; wherefore it is called *πυλωρος*, or the Potter, commonly the neather orifice. In a
word, where on the left side the stomach is thick in his top, there his vpper mouth begineth
from the *oesophagus* or Gullet; where on the right side it is thicke and eleuatad, there is the
end of the stomach, and the beginning of the *Duodenum*.

But because when it is filled with meate and drinke, it might bee commodiously disten-
ded, and the vyands being distributed againe constringed and streightned, and in great
Meales when it is thrust full not be violated: For these reasons I say, the substance of it is
Membranous and Neruous, which when the stomache is corrugated or crumpled vp, is
thicke; when it is dilated it is thin. And verily in those that are much giuen to their pan-
ches, it is so enlarged and rarified that it can no more be corrugated, which oftentimes is
a cause of long weaknesse of the stomache; after such gourmandizing fits; for in whome,
soeuer the body of the stomache is thin, such men do worse concoct their meat, then they
that haue it fleshy and thicke.

It hath three Membranes or coates [tab. x. fig. 3] one common and two proper. The
first which is the vtmost and the common coate [tab. x. fig. 3. h h h] from the *peritoneum*;
yssue thence where it compasseth the *Diaphragma* at the vpper mouth: this addeth
strength to the proper coats. It hath right Fibres, and is the thickest of all the coats which
come from the *peritoneum*, because from it must arise the vpper Membrane of the *Omen-*
tum.

The second coate is altogether fleshy [tab. x. fig. 3. i] consisting of fleshy Fibres, which
being contracted, whatsoeuer is offensive to the stomache, is as it were wittingly vomited
vp; those Fibres also increasing the heate, do make much for the helping of concoction;
because for that office a great heate is required. This is immediately knit vnto that which
followeth: it hath also transuerse Fibres [tab. x. fig. 3. j] vnder which a few fleshy oblique
or side Fibres do lye. Some of which run from the vpper mouth, where they haue their
beginning euen to the *pylorus*, but more of them do descend to the bottome of the sto-
mack toward the *pylorus*. Vnder these about the left mouth, do arise circular fleshy Fibres
which do shut the orifice: but when the transuerse and oblique do moderately drawe the
stomacke together, it embraceth the meate; if violently or strongly, they driue the meate
now digested by degrees toward the *Pylosus*, because it looketh vpward, and the Chylus is
beaue.

The third coate is inmost and Neruous [table x. figure 3. k] into which the vessells them-
selues are ended: this is continued to the coate of the *oesophagus*, and of all the particles
which are in the mouth; because the mouth should admit of nothing that might be vnplea-
sant or distastfull to the stomache; and because the preparation to the first concoction is
made in the mouth. Hence it commeth, that when any chollericke humour or vapour is
raised vp, the tongue is defiled with bitternesse and yellownesse, and oftentimes the ex-
ulcerations of the mouth and the tongue are communicated to the *oesophagus*, and the sto-
macke, and theyrs againe to them: by reason of which consent, we cannot euacuate the

head by the Palate, but we must also euacuate or empty the stomacke.

The use of
the Fibres.

His third coat is wouen with three kinds of Fibres, that so the stomacke might bee the better extended. The right Fibres are very many and conspicuous aboue the rest, by which as it were by hands, they say it snatcheth his meate; by the oblique which are outwarde, it reteyneth it; and by the transuerse it expelleth it after it is labored and concocted. Al these are so thightly wouen one within another, that they will not appeare vnlesse they be distracted and rent or sluen asunder. This coate is also rugous and vnequall. In those beasts that chew the cud, harsh beside and rough, and distinguished into certaine proportionable inequalities, nor vnlike to the hony-combe.

It hath these foulds and roughnesse from a fleshy crust which ariseth out of the excrements of the third concoction of the stomacke, and serueth to defend it from any harde thing that should be receyued into it, least if it selfe were made callous, the mouths of the Veynes should be stopped, that neyther the Chylus could be sucked out of the stomacke, nor the stomacke be able to draw blood for his nourishment. It maketh also somewhat for the moderate retention of the meate; for by his corrugation and harshnes, it holdeth

Table x. sheweth the stomacke with the Gullet.

The first Figure the foreside of them both, with the vessels inserted into them. The second figure their backe sides. The third Figure sheweth the Coats and Fibres of the stomacke. The fourth figure sheweth the stomacke with the inside turned outward.

TABVLA X.

ddd 1, 2. The fourth veine cald *Coronaria stomachica*, with his artery, compassing the left mouth of the stomack. This is a branch of *Gastrica maior*. e 1. Certain branches from the branch marked with a descending from the top of the stomach, and running with their Artery toward the *Pylorus*. f 1, 2. The first veine cald *Gastrica maior*, deriued from the Splenick branch; which together with his arterie and nerues creepeth to the left side of the bottome of the stomacke. g 1, 2. Vessels deriued from those which passe to the spleene. h h h 3. The first and outmost coate of the stomacke from the *Periconaeum*. i 3. The second coate. k 2. The first and inmost parted in this place from the two other. l 4. A round swelling of the left orifice bending inward, where the Gullet is continued with the stomacke. m 4. A round swelling of the right orifice of the circle of the *Pylorus*. n 4. The inward superficies or surface of the stomacke.

A 1, 2. The Orifice of the Gullet cut from the throat.
B 1. The straight and direct course of the gullet from A to B.
C 1, 2. How the Gullet about the first rack bone of the chest from B to C, inclineth vnto the right hand in the first figure, and to the left in the second.
D 1, 2. His inclination to the left hande from C to D in the first Figure: but in the second to the right hand.
EE 1, 2. The two Glandules cald *Tonsillae*, or the Almonds set close to the gullet in the very end of the throat.
F 1, 2. Another glandulous body in the midst of the gullet about the 5. rackbone, but it lyeth vnder it. In calues we call this the sweet bread.
G 1, 2. The connexion of the gullet with the stomacke where the vpper orifice of the stomacke is fashioned.
H 1, 2. The 2. orifice of the stomack, cald *Pylorus*.
I K 1, 2. The vpper part of the stomacke at I, the lower K.
L L 1. The foreside of the stomacke.
M N O 2. The backside of the stomacke, and M sheweth the prominence of the left side, N of the right, but O sheweth the docke or impression, where it resteth vpon the racke-bones.

a 2. The first Veine of the stomacke, cald *Gastrica dextra*, or the right stomack vein coming from the trunk of the gate veine, and his Artery cometh from the trunk of the *Celiacall* Artery, both of them reach vnto the *Pylorus*.
b 1, 2. The second veine cald *Gastrica sinistra*, together with the Artery accompanying it, and a Nerue, all tending to the right side of the bottome of the stomacke.
c 2. The third Veine of the stomacke cald *Gastrica minor*, it wanteth an Artery for his companion from the splenick branch.

that

that which is raw or vndigested that it cannot fall out of it. This Crust is spongie, having small holes as it were short Fibres from the inward to the outward superficies, thar by these hollowe passages of his, the thinner part of the Chylus might pierce and be sucked away by the veines. This crust may be separated from the Membrane or coate in brute Beasts, yea also in the stomacke of a man if it be perboyled.

The crust of the stomacke.

The stomacke is not thicker or fleshier in the bottom then in other parts, nor as it is at either of the mouthes. Some say that in corpulent men there cleaveth a Fat to the bottom, on the left side; which when it is plentifull, they say a man may endure long before hee shall have any appetite to his meate.

The vesselles the stomacke hath are these. Sixe veines branched from the gate-veine, some of which come from his trunk, others from the mesentericall or spleenical boughes. From the trunk commeth the right *Gastricke* [table 10. figure 2. a.] which goeth to the right orifice; and the right *Gastra epiplois* [table 10. figure 1. 2. b.] from the mesentericall bowe attaineth to the middle of his bottome. From the spleene bow the lesser *Gastricke* [table 10. figure 2. c.] which goeth to his back-part; the greater [table 10. figure 1. 2. f.] *Gastricke*, from which comes the crowne veine of the stomacke, which in [table 10. figure 1. 2. d d d] mannee of a crowne incompasseth his left orifice or vpper mouth: the left *Gastroepiplois* disseminated into the other middle part of his bottome. And finally, that we call *vas breue* or the short vessell [table 10. figure 1. 2. g.] of all which we have intreated more particularly in the chapter of the gate or port veine.

The vessells of the stomacke Veines.

The office of these veines is to bring in blood for nourishment, for it is nourished continually as it was in the mothers wombe, that is, with blood not with Chylus, by which we grant it is delighted and refreshed, but cannot grant that it is nourished with it. Some few of these also while the Chylus is boyling in the stomach, do insensibly sucke out some small part of it (for they are but few in respect of those which determine into the Guts, because in the stomacke is celebrated concoction, but the Guts containe the Chylus already concocted, which it was fit should be with all expedition distributed) and do change it into blood by a naturall instinct, before it come to the Liuer, as *Galen* teacheth; haply that the membranes of the stomacke may with it be nourished. Or if thou hadst rather, say that these veines do carry the Chylus, that haue sucked after the manner of the *Meseraikes*, to the rootes of the port veine, that are disseminated through the Liuer, that there it may be turned into blood. From these veines come those sodaine refectiōs of the spirits by sweet and strong Wine, Broths, & Cordials; which refectiōs would not so soone follow, vnlesse the Liuer did suck nourishment by them out of the stomacke. That which is called the *vas breue* or short veine, which from the veines of the spleene is by an vnited passage of many branches carried into his bottome, doeth there belch out a sowe and shape juyce, sometimes to the vpper mouth to stirre vp appetite, (which yet properly is prouoked by sence of want) and to strengthen it by his adstringent vertue.

Their office

Gal. 4. v. 2. p. 12.

A good note of the sudden refectiōs which come from wine & cordiall potions.

It hath Arteries, from the Coeliacall branch of the *Aorta* [table 10. fig. 1. 2. ABDF] or great Artery, which doe accompany euery one of the veines, excepting the lesse *Gastricke* [table 10. figure 2. c.] to afford strength of life to preserue it from putrifaction, by ventilation to cherish, refresh and increase his naturall heate with their heat and vitall spirit, that so concoction might be made more perfect: but of these branches more hath beene sayd in the chapter of the Coeliacall Arteries.

The Arteries of the stomacke.

It hath very conspicuous and notable nerues from the sixth paire, which at his orificies or mouthes are double; [table 10. fig. 1. 2. T. V.] disseminated from those branches which make the recurrent nerues, and yeilde certaine Tendrilles to the lungs and the pericardium, or purse of the heart; which Tendrills because of their softnesse and the length of their way, are couered ouer with strong membranes, and do run crosse one another; that for greater security they might passe obliquely or aside-long; and piercing through the diaphragma or midriffe are on both sides doubly diuided: so that the left compasseth the [table 10. figure 1. 2. TVKZ] right and backe part of the mouth of the stomacke, and the right and left and forepart; which orifice they doe so inuolue, that it seemeth to bee made altogether of sinewes; from the abouandance of which, it hath most exquisite sence to stirre vp and awake the sence of the want of nourishment, which sence ariseth from suction; for there is the seat of the appetite; & to this onely part hath nature giuen the sence of want or of Animal hunger; so that we feele that part especially to be contracted when wee are extremely hungry. For if we should not feele a kinde of molestiō vpon the viters and absolute exsueti-

The nerues.

The cause of hunger.

The seat of appetite.

The appetite
of every parti-
cular part.

on of our nourishment till there be a supply made, we should by degrees be extinguished being affamished before we were aware; for our substance is in perpetuall wasting and decay; the inbred heate continually feeding vpon the Radicall moysture. But now it is otherwise, because the naturall hunger that is settled in euery particular part, hath with it adioyned a sence of discontent, which is onely appeased by assimilation of fresh nourishment.

Why the
brain being
stroken, the
patient casts.

These branches of Nerues going downward, make his membranes which were onely membranous before, to become neruous, being disseminated euen to his bottome. These doe also improue the nourishing force or faculty to the fleshy Fibres of the stomacke. From the left nerue there runneth a branch along the vppermost seate of the stomacke to the pylorus, which when it hath foulded with a few small furcles, it goeth thence to the hollow of the Liuer. To the bottome of the stomacke do other two nerues attaine from the sixt paire also, to wit, from the propagation led by the roots of the ribbes. Sometimes to the left side there are offered nerues arising from the sinewes which runne vnto the spleen.

Why the
brain being
stroken, the
patient casts.

Wherefore seeing the stomacke hath obtained so many sinewes, it is no wonder if when the braine bee stroken or affected, the stomacke also bee disturbed, and vomitings caused which happens also in the *Hemicrania* or Meigram: & on the other side when the stomack is affected, then the Animall faculty languisheth, & melancholly symptoms do happen: so that one of them suffering the other hath euer a compassion, not as most men haue of others miseries, but indeede a reall fellow feeling.

Vessels from
the bladder of
gall to the bot-
tom of the sto-
macke.

Furthermore, there attaineth to this bottome of the stomacke, sometimes a vessell or entrance of many vesselles from the bladder of Gall, carrying choller thither and causing perpetuall casting. A Family of such men are said to be at *Spire* in *Germany*, all of which family euery third day vomit vp a good quantity of Choller, & they be called *πυροχόλοι* *δυνα*, that is, casters of choller vpward.

The vse of the
stomacke.

The vse of the stomacke is to receiue meate chewed with the teeth, and drinke altered in the mouth through the gullet, and the same to retaine hauing contracted it selfe, and embraced them by closing both his orifices; and then his naturall inbredde faculty and proper heate, boyleth and conuerteth the better part of the Aliments into the white cream, which we call *Chylus*; that is, a substance disposed to be conuerted into bloud. For the proper action of the stomacke, sayth *Galen* 5. *usu partium* 4. is concoction, it being the organ or instrument of the first concoction, or the shop and forge of Chylification.

Galen.

What parts
assist the sto-
macks con-
coction.

Moreouer, because the substance of the stomacke is membranous, and therefore not so hot, his ingenit heate is encreased, yea doubled by the adiacent parts; as the Liuer, the Midriffe, the Spleene, the Kell, the Collicke gut, the trankes of the hollow veine and the great Arterie, the Sweet-bread; but especially the *Celiacall* Arterie, compassing it about almost on euery side yeeldeth most immediate assistance. For the narrower side of the stomacke toward the right hand, is in a manner hid vnder the Liuer; the left lieth close to the Spleene and so of the rest, which are all as so many coales set together vnder the vessell to make it boyle. After the Aliment is concocted, the pylorus or lower mouth of the stomacke is loosened, and the *Chylus* thrust downe into the *duodenum*, from thence to supply Aliment to the whole body: and so much of the stomacke.

Of the Oesophagus or Gullet. CHAP. X.

The reason
why we dis-
course of the
gullet in this
place.

The names.
*Hip. lib. de re-
sect. corpor.*
*Gal. 6. usu par-
ti. 5.*
Aristot. 1. hist.
Animal. 16.

Now although the *Oesophagus* or gullet is (for the most part of it) scituated in the Chest or second Region; yet because it is continued with the stomack, in substance, membranes and fibres little differing from it, being nothing else, but as it were a production of the same, we will intreate of it in this place, and not in the second Region, the rather because the Table wherein the stomacke is deciphered, containeth also the delineation of this *oesophagus*. It is called therefore in Greeke by *Hippocrates*, *Galen*, and *Aristotle*, *οισοφάγος* from *οἶσος* *καὶ* *φάγνμα*, which signifieth to carry meat, as also *σώμαχος* the stomack, from words that signifie length and narrowness. For indeed this name of the stomacke is proper to this part, albeit other authours, especially our English tongue hath turned it to signifie the ventricle or place where the meate is containd; the true stomack we call the gullet: the Arabians call it *meri* and *vescet*, the Latins *Gula*. It is the common way of meat and drinke from the mouth into the ventricle or stomacke as we call it, which all creatures haue

haue that draw breath. This part taking his beginning in the lowermost cauitie or hollownesse of the throate, at the rootes of [table 10. figure 1, 2. A, the orifice of the gullet cut from the throat] the round behind the larynx or wezon to whom it is tyed, and on either side toucheth the Tonfils or Almonds [tab. 10. fig. 1, EE] and passing through the necke & the breast, betwixt the wezon and [as appeareth in the table belonging to the chap. of the Lungs, figure 1, 2. where A sheweth the gullet, and B the arterie] the spondels of the necke and breast vpon which it leaneth; (for it might not passe through the middle cauitie of the brest, lest it should trouble some Instrument of breathing, and beside it stood in neede of some settled supporter and that farre within, to leane vnto, that so it might be safe from externall iniuries) it goeth directly [tab. x. fig. 1, 2. from A to B] to the first Spondell of the breast, where it enclineth it selfe a little to the right side, that it may [tab. x. fig. 1. from B to C] giue way to the trunk of the great Artery descending, which comming out of the left Ventricle of the heart, goeth necessarily to the left side ward. When it hath atteyned to the ninth Spondell, it is lifted aloft by the helpe of certaine Membranes, and passeth a boue the great Artery, least in the descending of grosse and thicke meates, it shoulde lye heavy vpon it, and hinder the course of the arteriall blood and spirits. Then againe it enclineth to the left side [tab. x. fig. 1 from C to D] where the vppermost mouth [tab. x. fig. 1. 2 G] of the stomacke is scituated, and going vnder the hollow Veine, passeth through the Neruous part of the *Diaphragma*, by a posture of his owne into the lower belly, and is implanted not into the right, lest it should necessarily perforate the Liuer, but into the lesse orifice of the stomacke, together with two Nerves [tab. x. fig. 1. 2. T V.]

In his originall or rising, it is tyed to the throate by a coate that compasseth the mouth, but to the stomacke (where it groweth to the *Diaphragma*) by the continuation of his body to the bodies of the Spondels; to the wezon and the parts adioyning by the helpe of Membranes proceeding out of the Ligaments of the backe.

His figure is round, [tab. x. fig. 1, 2] both that more matter might passe in lesse roome, (for of all figures the round is most capacious) and that it might be safer from iniuries. Very long it was of necessity to be, because the mouth is farre from the stomacke; and it may well be called a reddish gut, for after that manner it is distended into a sufficient capacity, that the meate should not stay in it, or pressing the wezon hinder respiration, and put a man in danger of choaking.

The substance of it is in a meane betweene flesh and sinnewes, (wherefore it may bee both enflamed and subiect to convulsion also:) sinnewy or membranous, that it might be extended into length and breadth when the meate is put in, and againe fall, that it take not too much roome when it is empty; fleshy it is also, that being soft it might giue way vnto the meate as it passeth downe. But because as a sacke to be filled with Corne, vnlesse it be held vp and open, doubleth into it selfe when the corne is powred in; so least the gullet being soft, should double into in selfe, when the meate is powred into it; it is supported and held open by his connexion to the bodies of the Spondels. Hence it is, that lying vpon the long ridge bone, when it is affected we apply Cataplasmes to the ridge of the back. It hath three Coates, one common and two proper. The first bred out of the Ligaments of the Spondels, which is the Case or couer of the two proper Coates. The second, which is called the externall, is fleshy and very thicke, as if it were a pertorated Muscle, and hath his originall from the second Cartilage of the wezon, as it lookes toward the necke, and hath onely transuerse Fibres, that with these the Aliment that is drawne by the fibres of the inner coate might be more readily thrust into the stomacke; they are also a great help when the stomack violently laboreth to vomit vp any thing that oppresseth it: which two things are after a diuerse manner performed. For if the fibres do beginne to be contracted aboue, they serue to swallow with: if from the Orifice of the stomacke, for vomiting. The thirde coate is internall, and of a dissimilar substance, vnder or within whose inward superficies, a certaine smooth and slippery veyle or wimple is substrated, hauing right and slender fibres to draw the nourishment after the mouth hath receyued it. The remainder of his substance from which that veyle or filmy couering like the Cuticle from the skin may be separated, is Neruous and more Membranous then the externall, more harde also and sensible, that the pleasure and good relish of meats and drinckes may be better apprehended by contaction or touching. This Coate ariseth from that which inuesteth the palate, the mouth, lips, and throate; and runneth as farre as the left Orifice of the stomacke. It hath very few oblong fibres, lest they should keepe the meate too long in the gullet, which would haue

To what part
it is tyed.

The Figure
of it.

The substance

His connexion.

The 3. coates
of the gullet.

beene a great annoyance to the wezon. That these may be the better obserued, they had neede be parboyled, to take away their abundant moysture.

The act of
swallowing.

The act of deglutition or of swallowing, is a worke mixed of an Animal and Natural, & is helped by certaine muscles called *oesophagæi*, belonging to the gullet; but they are accounted among the muscles of the wezon, which proceeding from the sides of the gristle called *Thyroïdes*, doe wholly embrace the gullet, and being parted by a right line, are inserted into his middle part, as we shall see more at large in the booke of muscles.

The Glandules
or Tonils
called the Al-
monds.

For the facilitie of swallowing, the cavity of this gullet is alwayes moystened by the glandules that are set neare vnto it. In the throate by the glandules that are common to the gullet and to the wezon, which containe the spittle, and [table 10. figure 1. EE] are called *Tonsilla* or the Almonds; again, by a glandulous body that on the backpart, [table 10. fig. 1. 2. FF] and toward the sides groweth to his middle passage, commonly in a Calfe called the sweet-bread; as well to moysten his cavity and defend him from the hardnesse of the spondels, as also to hold him steady from inclining to either side.

His vessels.
Veines.
Arteries.

It hath veines (but very few) from the hollow veine and the Coronarie branch of the [table 10. figure 1. 2. dd] port or gate-veine; Arteries from the great Arteries descending trunk, and from the coronarie branch of the *Celiacall* Arterie [table 10. figure 1. 2. dd]

Nerves.

His Nerves are very notable, coming from the sixt paire [table 10. figure 1. 2. TV] which for security sake are carried side-long; (the oblique way being much more safe then the right) for, being soft and slender, and to be led a long way, they might easily bee stretched or broken by the waight of the stomacke, if they had been led right on: which nerves when they haue encompassed the gullet round, at length are fastned in the stomacke, [tab. 10 fig. 2. XY.]

The vse of the
gullet.

The vse of this *oesophagus* or gullet is, that by it as it were by a tunnell, the meate and drinke, a little altered in the mouth, and turned ouer the rootes of the tongue by his muscles to the begining of this gullet, might by it be receiued, whither when it is arriued, the throat and parts of the gullet about the meat closing themselves, and those below being dilated, the meate and drinke are driuen downe into the stomacke.

An obserua-
tion with the
reason of an
vncouth acci-
dent.

It is worth the obseruation, that with some men solid bittes finde freer passage then liquid drinks or broths, which are often returned into the nose, and this hapneth vsually in those who haue beene long afflicted with the Chollicke: as also in a false squinacee.

The cause of this accident is to bee imputed to the resolution of the muscles of the choppes, for solid things with their waight offer a kinde of violence to the muscles, and make their owne passage, but liquid things cannot doe so. Although I am not ignorant that there may also be another reason rendred hereof, to wit, a tumor or inflammation of the glandules before mentioned; for solide meates doe presse them and so open the cavity, to make way for themselves.

CHAP. XI. Of the Spleene or Milt.

THE Milt is called in Greeke *σπλήν*, because it draweth away the droffe of the bloud, as they say Lupines among wheate doe sucke away the bitternesse of the earth; in Latine it is called *Lien*. It is placed in the [table 11. 00] vppermost part of the inferior *venter* or lower belly, in the left *Hypochondrium*, vnder the midriffe towards the backe: wherefore in hayle men it cannot bee felt, but in those that haue swollen spleenes, it may not onely be felt, but sometimes seene to bunch out a good way in the *Abdomen*. The embowed part [table 11. 00] resteth vpon the spondels and bastard ribs which are a defence vnto it; the concaue or hollow part [table 11. P] turned to the right side, is opposite to the Liuer, as if it were a left Liuer. It is seated either higher or lower in diuerse bodies, betwixt the stomack & the ribs, for there onely was a roome empty for it. Commonly there is but one spleene, yet sometimes two and three; one on the top of another; neuer of an equall bignesse, but distinct in their coates and vessels: it is wondrous rarely absent, and very rarely doth it change places with the Liuer, that it should be in the right side, and the Liuer in the left. It is knit to the Rimme or *Peritoneum* and the *omentum*, sometimes more outwardly to the *diaphragma*, and to the externall membrane of the left Kidney with very slender membranes, arising from the *Peritoneum* where it compasseth the *Diaphragma*, for it had not neede of so strong bands of the Liuer, because

because it is nothing so waighty; sometimes inwardly, forward to the stomacke, backward to the backe alwayes, by the interposition or mediation of vessels and of the vpper Membrane of the *Omentum* [tab. xii. fig. 2 C C] which cleaueth to the Line [tab. xi. P. Tab. xii. fig. 2 H H] of the Spleene.

It varieth much in his Magnitude, colour, and figure. For in a man it is thicke and great, but much lesse then the Liuer, that it may not hinder the dilatation of the stomacke. In some men it growes greater; for by reason of the loose rarity of his substance, it easily encreaseeth by the affluence of humors; especially it groweth in those men in whom naturally there is more plenty of Melancholy iuice: and although this humor in respect of the Choller and Vrine be but little, yet because it must be drawne a long way, and is stubborne

TABVLA. XI.

O O. The fore-side and hollow side of the Spleene, which also sheweth how his position is in the body of Man.

P. A Line into which the Vessels of the Spleene are implanted.

and refractory by reason of his thicknesse and vnwilling to follow, therefore the Spleene is ordained somewhat the bigger. It hath not alwayes the same colour. For in an Infant when it is nourished with pure blood defecated by the mothers Spleen, it is red like the Liuer; but in growne bodies where it is nourished with a thicke iuice, it is more then rufser toward blacke; for such is the naturall colour of the Melancholy humor. But in those that are diseased in their Spleenes, such as is the humor that offends, such is the colour of the Spleene, Liuid, Leaden, Ashy or Leeke greene; sometimes it is couered with a coate very like a Cartilage, in colour, thicknesse and hardnesse; in Dogges it is of a brighter red then the Liuer.

His Figure [tab. xii. fig. 2] he varieth according as the parts which lye neere him do require, yet is alwaies so long as the vncovered or naked left side of the stomack will admit. It is also broad and somewhat square like an Oxe tongue, or as *Hippocrates* hath it, like the soale of a mans foote. Aboue it is broader and ends in a double obtuse & blunt Angle or corner. Below narrower and ends in one narrow corner or angle. Without and on the left side, and as it looketh to the *Diaphragma*, somewhat gibbous or embowed, so that it hath a little representation of a globous or round figure. Sometimes from the ribs it hath [tab. xii. fig. 4. L L] certaine impressions or distinctions. Inward, and on the right side somewhat concauons [tab. xii. fig. 2. betweene H H] or hollow, that it might giue way, or rather enclose the stomacke, and so further his concoction. Through the middle length of this

cavity

The colour;

A good note;

The Figure;

cavity, runneth a white line [table xi. P and tab. xii. fig. 2 HH] which hath some rising inequalities in it, which receyue the Veines and the Arteries [Tab. xii. fig. 2 N] and the Kell, [tab. 12 fig. 2 BB.] as followeth.

The second Figure sheweth all the sides of the Spleene taken out of the body. The first peece the fore-side with a part of the Kell and his vessels. 2 the hollow side, 3 the gibbous side, the 4 sheweth the impressions which sometimes it receyueh from the Ribbes, the 5 sheweth the hollow side slit open.

TABVLA XII.

- A. The left side of the Spleene, for the right and the middle part is covered by the Kell.
 B B. The lower wing of the Kell, in which the vessels are led.
 C C. The upper wing of the Kell, through which the vessels passe to the stomacke.
 D E. the upper part of the Spleen D, the lower E.
 F G. The right and the left side of the Spleene.
 H H. A Line in the hollow side of the Spleene into which the vessels are inserted.
 I K. The substance of the Spleene dissected.
 L L. The gibbous side of the Spleen, with the impressions above mentioned, which are made by the ribbes.
 M M. The gibbous side of the Spleene, without these impressions.
 N. Veynes and Arteries which run vnto the Spleene.

The Splenicke branch of the Gate-veine [table 3 B] called *Ramus splenicus*, [table 3 F] below the Liuer is sent (a great bow it is sustayned by the Lower Membrane of the Kell) [tab. xii. fig. 2 BB] ouerthwart to the Spleene (allowing first some few branches from it, described in the history of the port-veine) and being diuided in his cavity, [tab. xii. fig. 2 HH] is spent in his substance [tab. xii. fig. 2 IK tab. 3. aaaa. tab. 4. fig. 2 ll m] into much smaller branches, not conspicuous as in the Liuer, but so smal and fine (vnlesse it be a few of them) that they rather seeme to be Fibres then vessels: ouer and through which vessels, runnes a thicke and grosse blood, making the proper substance or flesh of the *Milt*.

The course of the Melancholy humour.

How Melancholy prouoketh appetite.

Vas breue.

Vomits how good in quartane Agues.

This *Milt* or Splenicke branch carrieth to the Spleene a thicke iuyce, the more earthie part of the blood, that there it might be wrought into his nourishment. But because some part of this iuyce is so grosse that it cannot be attenuated by the Spleene, and therefore as vnprofitable must be segregated or separated, there are ordained two kindes of Vesselles to receyue it; one which belcheth it out vpward into the left side of the bottome of the stomacke, sometimes vp higher toward the left orifice, where with his sowrenesse he stirreth vp the Apperite after the Chylus is gorten into the Veins of the Liuer: so wee imitate nature, when wee make sowre or sharpe fauces at supper, to prouoke and recall our appetite which by our dinner was extinct and lost. Again, this humour hauing a binding faculty, strengthneth the stomacke, that his actions may be more firme.

This regurgitation or belching of melancholy, is made sometimes by three, sometimes by many branches proceeding from the Splenicke branch; sometimes by one, proceeding from the vppermost branch nere the Spleene, which *Galen* calleth *Vas breue*, that is, the short Vessell, described before in the 3, and 4. Tables. Hence comes sometime castings of a blacke humor, which is after carried downe the guts with the Chylus, and so excluded. This Vessell also is of great vse in Quartane Agues; for by it such patients are to good purpose by vomit purged, before and after the fit: for in these Agues, as also almost in all melancholy diseases, not only the *Milt* but the mouth of the stomacke is affected. There is also another vessell by which this humour is carried downward, which beeing inserted at the end of the right gut, maketh the inward Hæmorrhoidal [tab. 3 g g. tab. 4. fig. 2, *] Veines, for the outward come from the hollow veine; although this humour bee often purged

purged by the Arteries, not onely into the guts, but more often into the emulgent veines, and so through the Kidneyes into the bladder. And so wee imitating Nature in melancholy diseases vse *diureticks*, or medicines prouoking vrine.

*Diureticks
medicines in
quartane a-
gues & mel-
ancholly di-
seases.
The arteries;*

The spleene also receiveth many Arteries (more then the Liuer) and these very [table 4. figure 1. n.] great, the Coeliacall [table 4. figure 1. m.] which commeth out of the *Aorta* or great Arterie vader the *Diaphragma*, after the same manner and with the same number of diuisions that the veines haue, not onely that they may afford him life, but also that by their perpetuall motion they might preserve in good state the body of the spleene, by ventilating, cherishing and refreshing his naturall heat, almost oppressed with a drossie iuyce, which iuyce they change into a thicke blood for the spleenes nourishment, and the drossie is purged or auoyded away as we haue sayde. Beside, these Arteries carry to the *Aorta* wheyey humors, together with a thin and cold blood, which are received by the *Anastomosis* or inoculation of the vesselles; which humours by the emulgent Arteries are deriued into the Kidneyes; and from thence comes that quantity of vrine or whey which is in the great Artery.

The nerves;

It hath Nerves inserted into his coate very small ones, from that branch of the sixt paire which commeth from the rootes of the ribbes on the left side, but whether they passe farther into his substance we yet doubt.

It hath but one coate, and that very thin, springing from the membrane of the Kall, which we sayd claue to the right line of the spleene, and was a production of the *Peritoneum*, which coate compasseth and defends his flesh on euery side, because it is very soft and loose.

His substance [table 12. figure 5. I K.] seeming to bee nothing else but a thicke blacke and congealed blood full of fibres, for it is a *Parenchyma* as *Erasistratus* called it, or a fleshy affusion, very soft, thin, loose and spongiouse, that it might more easily draw thick iuyces from farre (for a spongie substance is fitter for that purpose then a fast and firme) and giue them entertainment: wherefore also the veines disseminated through it, are softer and looser then others, that the humour may more easily, though it be thicke, fall out of them.

*The flesh or
Parenchyma;*

The vse of the spleene, *Erasistratus* thought to bee none at all; inconsiderately accusing Nature to haue framed it in vaine. The receiued opinion is, that it was ordayned to bee a receptacle of the crasser and more foeculent part of the blood, made and separated in the Liuer, like as the bladder of gall is the receptacle of yellow choller; that the blood being thus on either hand depured, might passe more cleare and neate to nourish the body, and especially the principall parts. This thick and impure blood yet mingled with much good and laudable, the spleene by the spleenicke branch of the gate veine, by an inbred faculty draweth vnto it selfe as familiar and of kin vnto his substance, which albeit the veins of the Liuer could not change, yet the spleene by reason of the perpetuall motion of his many & large Arteries worketh it into his owne nourishment: of which notwithstanding there remaineth an vnprofitable part which it belcheth out into the stomacke, by the *short vessel* to stirre vp appetite by his aciditie and sharpnes, and by his adstriction to corroborate and confirme the actions of the stomacke. But against this common receiued opinion, *Bauhine* in this place annexeth a long discourse, full of wit, but how consonant to truth, I will leaue to others to iudge. It shall be for the present sufficient to make his conceite knowne vnto you.

*Erasistratus;
The receiued
opinion of the
vse to the
spleene.*

If the spleene, saith he, had onely beene appoynted to stable an excrement, it should not haue been seated in the vpper but in the lower part of the *abdomen*, as the other receptacles of excrements are: for so would it more commodiously haue receiued so heavy and earthy an excrement.

*Bauhines con-
ceit of the vse
of the spleene,
His argu-
ments.*

Againe, seeing of all the humours there is least quantity of this melancholy, Nature would not haue made the spleene bigger then the bladder of gall, if shee had not intended some other office for the spleene, beside the receipt of melancholly.

Moreouer, if this had beene her only end, she would haue framed in the spleene a large cavitie where this humour might haue commodiously beene enterdayned, as she framed a cavitie for the choller in the bladder of gall.

Fourthly, we must know and vnderstand that no part ordayned for the separation of excrements, doth receiue & naturally auoyd them by the same passages, as we may perceiue by the Kidneyes and the bladder of gall. Fifthly, no part is nourished by the excrement which it attracteth but by laudable blood. Sixtly, as the passages of choller are disperfed through

through the substance of the Liuer, among the rootes of the gate and hollow veines, to draw away the excrementitious choller. So also should there haue been many propagations and tendrils from the spleenick braunch, disperfed through the substance of the Liuer, which we finde to be nothing so.

Finally, if from the Liuer the foeculent blood bee purged away, as an excrement into the spleene, then it must of necessity follow that this excrementitious humour should regurgitate or returne into the trunk of the Gate-veine, because the spleenick branch ariseth out of the same trunk far vnder the Liuer, and about the trunk of the *meseraicks*,

Wherefore we think, sayth *Bauhine*, that the spleene was ordained and instituted by Nature, for a further confection of some kinde of blood. Which vse, *Aristotle* first allotted vnto it, and therefore in his third booke *de partibus Animalium* and the 7. chapter, hee calleth it a bastard Liuer. The same also *Galen* giueth assent vnto, in his booke *de respirationis usu*, as also *Aphrodiseus* and *Aretæus*: *Vesalius* and *Fernelius*, touch vpon this vse of the spleene also; but *Platerus* and *Archangelus* resolute vpon it very confidently.

The spleene therefore from an inbred faculty of his owne, draweth vnto himselfe the thicker and more earthie portion of the Chylus, somewhat altered in hauing receiued a certain disposition or rudiment of blood in the *meseraicke* veines, by the spleenick branch of the Gate-veine, out of the trunk of the *meseraicke* veines before the Chylus get into the Liuer; that so the Liuer may the better draw the more laudable parts of the Chylus, for otherwise the small vessels of the Liuer being obstructed by the crasse and crude blood, not onely sanguification would haue beene interrupted; but also the Jaundise, Dropsies, Agues, Scirrous hardnesse, and many other mischiefs, would haue ouertaken vs of necessity, all which we see do euery day happen when the spleen fayleth to do his duty; & either through weaknesse, or obstructions, ceaseth to attract that crasse and foeculent part of the Chylus. But a great euidence of this truth is this; that the spleenicke branch doeth not proceede from the Liuer, but ariseth as is sayde, and is seated below it. Neither is it likely that so thicke a iuyce confection and made into blood in the Liuer, should get out of it by the hairie and threddy veines of the same; yet we do not deny that melancholy iuyce is ingendred in the Liuer; but we say, that that onely is there ingendered which is a part of the masse of blood, not that which is receiued into the spleen, for his nourishment and the vse of the stomacke.

Furthermore we are of opinion saith *Bauhine*, that a part of the Chylus is sucked euen out of the stomacke, by veines ariuing at the left side of his bottom from the spleenicke branch. When the spleen hath receiued this Chylus a little altered in the long iourney through those spleenicke surcles and branches, it laboureth and worketh it at great leasure, and by long processe, as the Alchymists say, and much preparation in the innumerable small vessels or Fibrous complications which are disseminated through his substance (like as the other and greater part of the Chylus is laboured into blood in the complications of the vessels disseminated through the Liuer) and boyleth it into a thinner consistence by the help of naturall heate assisted by the many and large Arteries, and their perpetuall motion. And then a part of it becommeth the Aliment of the spleen, the rest is carried by veines issuing from the spleenick branch, to nourish the Stomacke, the Guts, the Kell, and the Mesentery; which thing *Galen* also insinuateth, when he sayth, That the same *meseraicke* veines do carry Chylus vnto the Liuer out of the stomacke and the guts, and returne blood againe vnto them and the *omentum*. For seeing that the originall and substance of all the veines which are propagated from the gate-veine is one and the same; it followeth necessarily, that their action also should be the same; but to returne.

A part also happely of this humour thus altered is drawne into the next adioyning arteries, and so conueyed into the great Artery, to contemperate the intense and sharp heat of the blood in the left ventricle of the heart, and to establish and settle the nimble & quick motions of the vitall spirits, which are a very great cause why some mens wits are so giddy and vnconstant.

Sometimes it falleth out in great and confirmed diseases of the Liuer, when his sanguification is decayed or in a manner perished, that the spleen performeth his office, and transmitteth a part of the blood by him laboured through the spleenicke branch vnto the veins of the Liuer, which through the rootes of the hollow veine and the branches thereof, is distributed into the parts of the body for their nourishment, euen as the blood is wont to be distributed, which is laboured and confectioned in the Liuer it selfe.

Bauhine pro-
iect,

Galen.

But that part of the altered Chylus that before we sayd was drawn into the spleen, which it cannot by reason of the thicknesse thereof transforme into profitable iuyce, but is altogether vnapt for nourishment, is poured out, part of it into the stomacke, part into the *Hemorrhoid* veines; sometimes through the trunk of the gate veine, or through the splenick Arteries it is deriued vnto the Kidneyes, whence it is that in diseases of the Spleene, the water fals out often to be blacke.

why in affect
of the spleene
the vrines are
often blacke

Wherefore wee conclude saith *Bauhine*, that the Spleene is a great helpe to the Liuer for the confection of blood; partly because it maketh blood answerable to his owne Nature, partly because it auerteth or draweth aside vnto it selfe the thicker part of the aliment, not so fit to make pure blood, and by that meanes the Liuer, vnburdened of such a clogge, performeth his office of sanguification with more facility. And thus it may be sayd verie well to purge and defecate the blood, and to make it more pure and bright. And heereupon the Ancients placed the seate of laughter in the spleene: and *Plato* saith, that the spleen polisheth and brightneth the Liuer like a Looking-glasse, that it might make a more cleare representation of the Images of the passions from thence exhibited vnto the soule.

Plato

Aristotle also calleth it a left Liuer, and obserueth that those creatures which haue no Spleene haue as it were double Liuers: and *Galen* remembreth in his fourth Booke of the vse of parts, and the 7. chapter, that *Plato* calleth it the expresse Image of the Liuer.

Aristotle

It is therefore not to be wondered at, if the diseases of the Spleene doe no lesse (haply more) hinder sanguification then the diseases of the Liuer it selfe, because by how much the better the spleene doth his duty, by so much the blood in the Liuer is more pure and cleare.

In Dissections also we often finde, that the Spleene exceedeth the Liuer in magnitude, or is equall to it, being yet found in colour and consistence.

Notwithstanding, albeit in both these entralls, when a man is sound, and hayle blood is generated, yet it must needs be confessed, that there is more store of good & hot blood fit for the nourishment of fleshy parts made in the Liuer then in the Spleen, whose blood is neither so much, nor so hot, nor all out so good; which *Hippocrates* intimateth when he saith, that the same things which make the Spleene to flourish, make the body to wither and consume.

And thus I haue acquainted you with *Bauhines* conceits of the vse of the Spleen, wherein me thinks he acquitteth himself, as *Bellarmino* doth in his disputations of the sufficiency of works in our Iustification, who after that in diuers Books, and by manifold arguments hee endeoureth to proue that works may iustify, yet in the end he concludeth, that it is more safe onely to trust to iustification by faith; so *Bauhine* for all his former arguments, yet you see concludeth, That the more, better and warmer blood is made in the Liuer: as if hee should say, there is a little & cold blood made in the spleene, not fit to nourish the fleshy parts, but onely his owne substance, which I thinke no man will deny vnto him. But of this question we shall see more heereafter in the Controuersies; we will now put an end to our discourse of the Spleene, adding this one vse more of it; That with his in-bred heate, and the many Arteries wherewith that heate is encreased, it furthereth the concoction of the Stomacke.

Bauhines cau-
telous conclu-
sion.

CHAP. XII. Of the Liuer.

THE Liuer is called in Greeke *ἥπαρ*, from a word that signifieth *Want*, because it supplieth the want of al the parts; or from making merry, because in this part is the seate of concupiscence. The Latines call it *Iecur*, as it were *Iuxta Cor*, because next to the heart his power is most eminent. It is worthily numbred among the principall parts, as being the seate of the naturall faculty, and of the nourishing part of the soule, common to all sanguine or bloodie creatures: and first of all the Entralles or bowels it is perfected in the mothers wombe.

The notation

A principall
part.

It is the beginning of Veines, not in respect of their originall, which is seed (for the vessels are made before the *Viscera* or entrals) but in respect of their rooting & distribution; for from hence spring two great and long Veines; below out of his cavity or hollownesse the Port or Gate veine; about out of his conuexity or embowed side, the hollowe veyne

The begin-
ning of veines.

is

is sayd to proceede, albeit indeede the hollow veine groweth to his backe [tab. xiii. Fig 1, FG. fig. 3 MN] part, with two notable branches disperfed through his substance, which two vesselles arise out of the Liuer (the *Parenchyma* or flesh of it being compassed about their roots as the earth is about the roots of a tree) and doe minister nourishment to the whole body, wherefore the Liuer is called the shop of sanguification or blood-making.

His situation

It is placed in the [tab. 6. lib. 2. FF tab. 9. CC] vpper part of the lower belly, that being set in the midst as it were of the body, it might send blood equally vpperward and downeward; it is about a fingers breadth distant from the *Diaphragma* least it should hinder his motion; in dead bodies sometimes it toucheth it, and is covered wholly by the ribbes. It taketh vp the greatest part of the right *Hypochondrium*, partly that it may leaue the left for the stomacke [table 6. Lib. 2. FF. table 9. FF] and the spleen [tab. 9. G] (for these three occupy both sides; whence it is that when any of them, much more when all are swelled, there followeth great difficulty of breathing) partly because the blood might be better carried to the right ventricle of the heart. It leaneth but lightly vpon the vppermost, foremost, and right side of the stomacke [see the tab. 6. lib. 2. and tab. 9.] least it should presse it with his waight, and driue forth the matter contained in it. A little part of it also reaching toward the left side, that the body might be ballanced. In Dogs it taketh vp well neere both sides, because their spleenes are long and narrow, but the greatest part is compassed below with the bastard ribs which defend it from iniuries.

The Figure.

His figure is diuerse, because of the parts [table 13. figure 1. 2.] adjacent, for his office. Table xiiij. sheweth the Liuer with his Veines.

The first Figure, the Gibbous and forepart.

The second Figure, the Gibbous and hinder part, together with a part of the trunk of the hollow veine.

The third Figure, a part of the hollow veine fastned to th backside of the Liuer, and is opened with a long slit, to shew the holes of his branches where they open into the Liuer.

- AA 1. The Gibbous and fore side of the Liuer.
 B 1. The Vmbilicall veine.
 CC 2. The gibbous and backside of the Liuer.
 D 2, 3. The seate of the hollow veine where it passeth through the midriffe.
 E E 2. The veines of the midriffe called *Phrenica*.
 FG 2. In this distance is the place where the trunk of the hollow veine groweth to the backside of the Liuer.
 H 2. A Ligament which tieth the Liuer to the midriffe.
 I 2. A Ligament tying the left side of the Liuer to the midriffe.
 K 2. A part of the Gate-veine.
 L 2. The bosome of the Liuer into which it admitteth the left orifice of the stomacke.
 MN 3. Certaine branches of veines proceeding out of the Liuer.
 OO 3. Smal branches which are thrust out of the Liuer to the hollow veine.
 PP 3. The roots of the hollow veine disperfed thorough the Liuer.

The fourth figure sheweth the roots of the Hollow and Gate Veines disperfed through the Liuer and their Anastomoses or inoculations.

- A. The trunks of the hollow veine arising vpperward from the Liuer.
 B B The trunk of the hollow veine, as it getteth out of the Gibbous part of the Liuer, which is bent downwards, and watereth all the parts of the body vnder the Liuer.
 C C C C. The roots of the hollow veine which are in the substance of the Liuer.
 D D D D. The ends of the roots of the hollow veine which pierce or open into the midst of the roots of the gate-veine.
 E E The principal trunk of the gate-veine.
 F F The roots of the gate-veine, even all those that are black, disperfed through the substance of the Liuer, which vnder the lower part of the Liuer do meet, and make one trunk.
 G G G G. The ends of the rootes of the gate-veine which pierce or open into the midst of the roots of the hollow veine.

requires

requires no proper figure: but a sufficient magnitude and thicknesse.

The forme of it is outward or inward: the outward forme or surface which is the vpper & more backward part is smooth, equall and conuexe or embowed [Tab. 8. B G. Tab. 2. lib. 4. bb, Table 13, Fig. 1 AA, Fig. 8 CC] round (which is called *parts gibba*, the gibbous part or the head) that it may giue way to the *Diaphragma*, and may agree with the cavity of it; but backward it hath a [Tab. 13, Figure 2, at FG] long bosome sufficient to embrace the stumpe of the hollow veine [Tab. 13, Fig. 2 FG] lest it should be pressed eyther with the Liuers waight or the motion of the Midriffe.

The Figure,

The inward face of the Liuer which is the lower, is [Tab. 8. CC. table 11. BB. table 15, Fig. 1. BBC] hollow, vnequall, and is called the *Sinus* or saddle side, that it may giue way to the stomacke strutting [Table 9. FF. Table 11 E. Tab. 2, lib. 4 CC] with plenty of meate, and couet it immediately to cherish the first concoction of the Chylus.

In this part there are two hollowes or bosomes, one on the right side to receive the body of the bladder of Gall, [Table 15. Fig. 1, F] the other on [Tab. 13. Fig. 2, L. tab. 15, fig. 1 H] the left side, where it giueth way to the passage of the stomacke. In Dogs it hath a priuate hollownesse, whereinto it admitteth a part of the right Kidney. But where the gate-veine getteth out of it, it is vnequall, because it riseth somewhat high, least the Veines should be pressed by the racke bones. On the right side it is round [Tab. 9 CC, Tab. 13, Fig. 1, AA] and very thicke; on the left it groweth thinner by degrees, and endeth somewhat sharpe in an acute Angle; [Table 13, Fig. 2, from L to I] in the forepart also it is thin in the bought or compasse. There is but one Liuer, for the largenesse makes recompence for the number; and it is the greatest in a man of any creature for his proportion, and in the biggest men biggest, because it must make blood for the vse of the whole body; not onelie for his nourishment, but also to serue for his expence of spirits: for there are more functions of the soule in a man, then in any other creature; which functions spend more animall Spirits, and those are engendred of the vitall spirits, and the vitall spirits of blood; therefore a man had neede of good store of blood, and by consequent of a great Liuer wherewith to make it. In fearefull men and such as are giuen to their paunches, it is greater then in other men. In fearefull men, because the weakenesse of their vitall faculty comming of the cold temper of the body, might be supplied by the strength of the natural faculty. In ravenous gourmandizers, because of the abundance of the meate they eate; for as the Liuer is more plentifully nourished, so it groweth greater. For the most part the Liuer of a man is whole (that when a man goes right vp, it might couer the stomacke with the hollow part of it) [as is shewed in the 6 Tab. lib. 2. and in Tab. 5] excepting the fore and right part where there [Tab. 13. Figure 1 at B, tab. 15 Fig. 1. E] is a cleft like an outlet, which was necessary for the passage of the vmbilical or Nauel vein. [Table 6, lib. 3, from D to B, tab. 5 e. tab. 8 1. table 13. Fig. 1 B.] On the backside a part of it filleth the cavity, which both the mouths of the stomacke do leaue.

The quality of it,

The waste of spirits in man above other creatures.

In what men it is greater or lesser.

But in brute beasts it is diuided into foure, fise, or six Lobes or Finnes, which are continued or coupled together, onely by the mediation of Veynes, within which lobes their stomackes are couered as it were with the fingers of a hand, because they haue no cloathes to keepe it warme, as men haue. For if in them it were whole, when they go groueling it would not so lap about the stomacke, but hang off. Wherefore Birds because they stande more straight vp, haue it diuided but once.

It hath in men no Lobes or diuisions.

It is knit to the spine bone of the Loynes, to the *Diaphragma*, and to other parts by the helpe of the Rim or *Peritoneum*, of whom it receyueth three strong Ligaments, least being heauy, it should at any time fall. The first and right is thin [Tab. 5 D, tab. 8 H, tab. 2 lib. 4, d. Tab. 13. Fig. 2 H] like a Membrane, broad, neruous and very strong, proceeding from the Rim where it compasseth the Midriffe; and tyeth the Liuer (into whose coates it doth degenerate) forward to the *Diaphragma*, and is called *Suspensorium* or the heauing Ligament: wherefore, when the Liuer growes heauy, the Midriffe is drawne downe and in that case in respiration there is more difficulty when a man stands, then when he lies along. The second and left Ligament is also very strong, round, [table 11. C. table 2, lib. 4. e. table 13, Fig. 2, 1. table fiftene, Figure one, G] and proceeding from the Rim; it knitteth also his thinner part to the *Diaphragma*, that the sides of the Liuer may on either hande bee held vp, it sometimes also cleaueth to the Cartilages of the bastard ribs. The third Ligament is the vmbilicall or Nauell veine, now dried after [table 6. lib. 2. from D to B. tab. 5. E. tab. 12. fig. 1 B] the birth, whereby at the Nauell the Liuer is tyed down to the *Abdomen*, [table. 23.

The Connection.

Three Ligaments.

Figure 7, 8. from Z to R] lest the falling down should draw the *Diaphragma* after it. Moreover, where the beginning of the Gate-veine is [Table 11. 7] there groweth to it a portion of the *omentum*. So on the backside in the compassed face or gibbous part where the hollow veine passeth through it, it cleaueth to the Rim.

The mem-
brane.

The Paren-
chyma.

It hath a most fine and slender membrane, and but one growing from that membrane of the veines which arise from the *Peritoneum* or Rim; & this incloseth all his substance.

That substance is nothing else but blood poured out of the veines, whence it is red and soft, and standeth round about and betwixt them, as the earth about and betwixt the small bearded rootes of a tree; which blood being held in by the membrane wee last spake of, cloddeth together, and therefore of *Erasistratus* is called *παρέγχυμα*, that is, an affusion or pouring out. *Galen* calls it flesh, *Hippocrates* a fleshy *viscus* or entrall: wee with *Galen* call *παρέγχυμα*, the flesh as well of this as of the other entrals.

The empty spaces betweene the rootes of the Hollow and Port veine this substance filleth vp, as may appeare when the flesh is taken away, for so it may be we haue seene it elegantly performed, and so haue by that oculte Anatomist *Petrus Pauus* of *Leyden* neere 30 yeares since, then my first Maister and moderator in Anatomie; a lively resemblance whereof wee haue here annexed, albeit it may partly be perceiued by the precedent Table.

Table 24. Sheweth the rootes of the Hollow and Gate veines, disseminated through the *Parenchyma* or flesh of the *Liu*er, and their *Anastomoses* or inoculations: also the trunks of the *Naue*ll, *Hollow* and *Gate-veines*. Into euery one of the trunks you may put a sticke before you boyle the *Liu*er and separate his substance from the vessels, that so the vessels may appeare open, and not corrugated or crumpled vp together.

TABVLA. XIII.

- A The trunk of the hollow veine where it pierceth the midriffe.
- B A part of the midriffe.
- CC A part of the trunk of the hollow veine which groweth to the back part of the *Liu*er
- DD The trunk of the hollow veine which is carried thorough the lower belly, his branches being remoued.
- EEEE The roots of the hollow veine dispersed through the substance of the *Liu*er: these appeare here all white.
- FG The vmbilicall veine, without the *Liu*er at F. within the *Liu*er at G.
- HH The trunk of the gate vein without the *liu*er.
- II A part of the right side of the gate veine torne from his left side, that the vessels might better bee demonstrated: but the trunk of the gate veine HH. should haue ridden ouer the hollow veine DD.
- KKKKKK The roots of the gate vein dispersed through the substance of the *liu*er, which here appeare all blacke.
- LLL The *Anastomoses* or inoculations of the gate veine with the rootes of the hollow veine.
- M This inoculation is like a Pipe or trunk, and it is a common and continued passage, into which you may put a good big Probe: from this there are open passages into the last strings of the gate or hollow veine.

The rootes of
the great veins

There are also a few Arteries inordinately shed through his substance amongst the other vessels. But there are more rootes of the port veine [table 13. Fig. 4. Tab. 14. the blacke rootes belong to the gate veines] in his lower part, and fewer in his vpper, and on the contrary

trary many more [table 13, Fig. 4. Tab. 14. the white rootes belong to the Hollow veine] roots of the Hollow veine in his vpper parts, then in his lower, (wherefore there is more plentiful sanguification or making of blood in the hollow side, and more abundant distribution in the conuex or embowed part) but all of them committed acrosse or mixt together by Anastomosis, [Tab. 13. Fig. 4. GGGG. Tab. 14. LLL] which most resemblerh the inoculation of plants; althogh sometimes the roots of the hollow Vein do fasten their ends into the midst of the roots of the Gate-vein, by which the blood runneth out of the roots of the Gate-vein into the Hollow vein, so that these roots do make *plexum mirabilem*, or the wonderfull web, texture, or plat of Veines (in respect of which it is likely the Liuer is saide to be the beginning or originall of veynes) for the perfecting and absolute confection of the blood. But there is one peculiar and notable Anastomosis or inoculation to bee obserued [tab. 14. M] which is a manifest and open pipe and continued passage into which you may passe a good bigge probe, and from which there lyeth an open way through all the least threds of the Gate and hollow Veines. And so much the rather are these inoculations of the Veines one with another, more diligently to be obserued, because through them the humors offending passe when the habite or vtmost region of the body is by Pur-gation emptied by the sidge.

Anastomosis
what it may
best be com-
pared to.

The lower [tab. 13, Fig. 4. FF. Tab. 14. KKKK] of these roots, are by little and little gathered into greater, and these into other, till at length in the lower part of the Liuer they consent together into the trunk of the port or the Gate veine [Tab. 13, Fig. 4. EE. Tab. 14. HH] as broad as a mans thumbe or broader.

The port or
Gate veine.
The Hollow
veine.

The vpper roots are in like manner [Tab. 13, Fig. 4. CCCC, Tab. 14. EEE] vnited by degrees; till at length they fall into two notable and great [Table 13, Fig. 3. MN] branches, reaching to the fore-seate of the Hollow veine, where it groweth to the Liuer, and lyeth vpon the *Diaphragma*, and there make one trunk. [Tab. 13. Fig. 2, F Fig. 3. D. Fig. 4. B. Tab. 14. AC.] Hence it is that the Gate-veine [Table 8, a] is said to arise out of the hollow side of the Liuer, and the Hollow veine, [Table 8, K] out of the conuex or embowed part.

Amongst these roots, certaine fine tendrils [Table 15, Fig. 2. Q Q. Table 16, Fig. 1. DDD, Figure 2, aaa] hauing the bodies of Veines, and being gathered into one stumpe or stalke [table 15, Figure 2, a. Table 16, Figure 1, E] are disseminated, which carry the choler from the Liuer to the bladder of gall, which also are ioyned with the rootes of the gate-veine, that the blood before it come into the branches of the Hollow veine, may bee purged and clenfed from that cholericke excrement.

The passage
of Choller to
the bladder of
Gall.

The same substance of the Liuer whereof wee spake before, by compassing about these vessels, strenghtneth them, and warranteth their tender threds from danger; by whom also it receiueh in lieu a proportionable good, for it is nourished by blood laboured in the roots of the Port veine, and out of those small ends powred on euery side into his lap: the remainder which he refuseth, is carried into the roots of the hollow vein, and thence both thrust out, and drawne for nourishment into the whole body.

How the Li-
uer is nour-
shed.

There are a few small Arteries [Table 4, Figure 1 M] from the *Celiac* diffused in his substance (which do appeare more white then the Veines) on the hollow side where the branches of the Gate [table 4, Figure 1 t, and Figure 2, t, table 11. L] veine do ioyne together into their common trunk or stumpe, that they might ventilate and so preserue the naturall heate of the Liuer, wherefore they runne onely through the hollow part; for the embowed part is waisted with the continuall motion of the *Diaphragma*, as with a Fan. They also carry vitall heate, that the heate being doubled, the sanguification might better succeed; and that the Liuer also might not be destitute of the vitall faculty: for in the whole bodye, the Veines and Arteries are in a league and helpe one another: these ministring spirits to the veines, the veines blood to them.

The Arteries
of the Liuer.

It hath two smal Nerues [Table 4, Fig. 2 y, tab. 11 M] from the sixth paire: one from that branch that is sent to the vpper mouth of the stomacke; [Table 15, Fig. 10, table 16, fig. 10] the other from the branch [Table 15, Figure 2 f] which passeth to the roots of the ribbes on the right side; both of them disperfed into his coate, that he might not be altogether like a plant without sense, albeit seruing onely for nourishment it stood in no need of any quick or notable sense, wherefore his Nerues are so very small. Hence it is, that the paines of the Liuer are not acute or sharpe, but obtuse or dull, and grauatiue onely. But the bottome or center of the Liuer is altogether without sense, because of the many motions of the humors therein

Why there is
no cavity in
the Liuer, but
a web or net
of veſſels.

The naturall
inſtinct of veſ-
ſels.

The vſe of the Liuer is by his affuſed ſubſtance to part and ſeparate the veſſels that they cleaue not together; to ſuſtaine and eſtabliſh them: to cherriſh them with his heate; be-
cauſe in that place their coats are thinner, ſaith *Galen 4. of ſuperpartium* 13. than in any other
part of the creature. For by this helpe, ſanguification which is celebrated in the rootes of
the gate veine, which are in the ſubſtance of the Liuer, is duly adminiſtered: to affoord vnto
them the Naturall Faculty as it were by irradiation, euen as the veſſels of ſeede receiue the
faculty of Seed-making from the Teſticles; as alſo to procreate the Naturall ſpirite, which
ſome denie, but *Archangelus* by many arguments doth eſtabliſh: and laſt of all to preſerue
and maintaine the Nouriſhing Soule as they call it, which is ſeated in euery particular part
of the body.

But becauſe there are many opinions concerning the manner of ſanguification, I haue
heere thought good to ſet downe *Baubines* conceite, as the opinion of a man to whome I
am eſpecially in this worke beholding.

All Aliments as well ſolid as liquid are taken by the mouth and after maſtication or
chewing as there is more or leſſe neede, are ſwallowed into the ſtomacke and there conco-
cted and turned into Chylus. This Chylus, aſteward when the pylorus or lower mouth of
the ſtomacke is opened, is thruſt downe into the guts: and if any part of it eſcaped elabo-
ration before, is there reuiſed and re-concocted. The thin and lawdable part of the Chy-
lus (for the thicke excrements called *Aluinaſeces*, are forced into the great guts) together
with that humour which is as it were a watery excrement, and was engendred in the con-
coction of the ſtomacke, is ſuckt away by certaine branches of the Gate-vein deriued from
his trunk (which is fixed in the hollow part of the Liuer) vnto the ſtomacke, but eſpecially
vnto the guts. Theſe veynes which are called *Vena Meſeraica*, and wee muſt call the Meſe-
raick veines, do attenuate the Chylus which they receyue, prepare it and giue it the fyrſt
rudiment of blood, ſo that now it beginneth to be called *Chymus*, that is, a Humour: which
when it approacheth to the trunk of the Gate-veine, is vnburdened of his thicke part, the
Spleene drawing it away by the Spleenicke branch, as hath bene ſayd in the vſe of the
Spleene.

That which remaineth of this *Chymus* or *Humour*, is conueyed out of the trunk of the
Gate-veine into his rootes which are very many and very ſmall, diſperſed through the hol-
low-part of the Liuer. Their coate alſo is very thin (as is alſo the coats of the veſſels of the
Spleene, the Teſticles and the Paps) that the Sanguifying Faculty might more eaſily inſi-
nuate it ſelf into them from the *Parenchyma* or fleſh of the Liuer, without which the blood
cannot be made profitable for nourishment; and from which thoſe veſſels receiue by irra-
diation the Sanguifying Faculty, as the ſpermatie do the Faculty of Seede-making from
the Teſticles. In theſe veſſels, therefore the *Humour* is changed into blood, for no Chylus
is powred out of the roots of the Gate-veines into the fleſh of the Liuer but *Chymus*.

Now that this *Humour* might be longer reteyned, and paſſing through many alterati-
ons be diuided into as ſmall portions as was poſſible, or rather be perfectly laboured, Na-
ture ordained no ſuch cavity in this place as in the ſtomacke; but of infinite & ſlender bran-
ches of Veines made a texture, net or web wherein the Chymus is better thinned, mitiga-
ted and parted into ſmall portions; that the fleſh of the Liuer on euery ſide compaſſing
his diſſeuered parts, might better worke it into a Maſſe of blood. For if there had bene a
cavity formed in the Liuer, then muſt the Chymus haue had a Canel or pipe for his egreſſe
and regreſſe through which it woulde haue ſalne away crude and not perfectly Sanguified,
and therefore vnfit for the nourishment of the parts.

After the blood is thus abſolued and perfected in the roots of the Gate-veine, they haue
a naturall inſtinct to part with it, partly to powre it into the fleſh of the Liuer for his nou-
riſhment that before did them ſo good an office; partly to vnload their burthen into the
rootes of the Hollow Veine, which are eſpecially diſſeminated through the Conexe or
gibbous and embowed part of the Liuer, which rootes alſo haue an inſtinct or deſire to
draw it into themſelues, and to deliuer it ouer into their boughes and branches (in which it
receyue a farther degree of elaboration) pure and defacated from all excrements, to be
distributed vnto the parts of the body.

The rootes of the Hollow and Gate-veines, although they be hand ouer head as we ſay,
without any precise order diſtributed through the fleſh of the Liuer, yet in manie places
they are ioyned by an Anaſtomofis or inoculation (excepting the branches which ſerue for
the nourishment of the Liuer it ſelfe) as they touch in their paſſage ouerthwart one ano-
ther,

ther, or else the extremities or endes of the gate veines are fastned into the midst of the rootes of the hollow veine; or contrarily the ends of the hollow veines into the midst of the gate veines: for after no other manner but this, can the blood be translated out of the rootes of the gate veine into the rootes of the hollow veine.

Anastomosis
how it com-
meth.

But that the blood might better passe through the narrow & straight passages of the vessels, it is wested by a thin & watery humour which is most like to whay; & therefore is called *serum sanguinis*, we call it commonly the Vrine, a humour which is not fitte for the nourishment of any part, but only mingling it selfe with the blood, it maketh it more thin, and so readier to passe along; wherefore *Hippocrates* called it *ὄχημα τῆς τροφῆς*, *The Wagon of the nourishment*.

The use of the
whay.

And whereas no Aliment is so simple, but that it consisteth of diuers and different parts; we must know, that all those parts cannot be changed into laudable blood; wherefore as in the first concoction celebrated in the stomach and the smal guts, there was a segregation of the excrements of the belly: so in the beginning of the second concoction, which was in the meseraicke veins, there was a segregation made of the crasse & foeculent part of the *Chylus*, from the pure & laudable, which was sent away to the spleene. But in the concoction which is accomplished in the veines of the Liuer, two excrements are separated, least if they remained mingled with the blood, they should be with it transported into the whole body. These through their proper passages are conuayed and stored vp in the peculiar and appropriated receptacles or places of receipt, The first of which, is the bilious or cholerick excrement, which is disposed partly into the bladder of gal, partly sent away into the guts, as we shall say in the next chapter. The second is, the *serous* or whaey humor, the greatest part whereof, when the blood is arriued out of the rootes of the gate veine into the hollow vein, becommeth an offensive burden vnto it; and therefore the Kidneyes by the emulgent veins and arteries draw it out of the hollow veine and the great artery into themselves.

The blood thus cleansed and depured from all manner of excrements, is distributed by the trunks and branches of the hollow veine through the whole body, in which passage it receiueeth an alteration or disposition of nourishment, that no time should be lost. These branches of the hollow veines doe with the blood carry also a part of the aboue mentioned whay or vrine, to make it more fluxible, that it might the better passe through the Capillary veines of the parts to nourish them; where when it is arriued, it is as it were sprinckled vpon the flesh, into which by little and little in manner of a vapour or dewe it soaketh and sinketh, cleauing like glew till it be wholly conuerted into the proper Aliment; which glew by nourishing and restoring, maketh good the Radicall moysture and the substance of the parts. But the whay which accompanied the blood thither in the third concoction, that is, in nourishment which is accomplished in every particular part, as an vnprofitable excrement is exhaled in sweat and insensible transpiration: thus far *Banbinc*.

CHAP. XIII.

Of the Bladder of Gall.

THe Bladder of Gal [Tab. 15. Fig. 1.2. PP] called *vesica biliaria*, or *folliculum felleum*, in greek *χοληδόχος*, is the receptacle of pure choller; and hath his seate in the right and hollow part [tab. 15. BB] of the Liuer, that it may be fitter to receiue the choller, which being a mad and hare-brain'd humour, had neede at the first generation of it be sent away, lest it should set all the body in an vprore; & therefore Nature placed his receptacle in the very bosome of the Liuer; his owne acrimony also hastneth his euacuation. The Liuer therefore hath as it were engraued in it a certaine cavity or bosome, wherein the vpper & middle parts of the Bladder are tyed firmly to it; the lower part in the meane time hanging loose from the body of the liuer, so as it toucheth the right side of the stomach and the *Colon*, dyeth them both oftentimes with a yellow colour; yea further affecteth them with his iuice sweating through his coates; whence it is not vnlike, that the burnings & flaming heates of some mens stomachs doe arise. The Figure of it is [tab. 15. Fig. 2.] long, that it might not be pressed by the stomacke, round also with his length and hollow, which hollownesse by degrees becommeth narrower, till at length it endeth in a necke.

It is small in respect of the spleene and the Kidneyes, albeit it draw a iuice both of a mid-

The situation.

The figure.

Why so small.

Table 15. The first Figure sheweth the lower belly wherein the stomacke with the guts are thrust into the left side: the Liver is lift up also, that you may better see the hollow side of the Liver, the bottome of the bladder of gall, the vessels which passe thereunto, and the passage of gall called Porus biliartus, which goeth unto the duodenum, and certain branches beside of the gate veine, together with a part of the mesenteric.

The second Figure sheweth the bladder of gall, his passages and vessels, as commonly Anatomistes make demonstration of them.

FIG I. Branches from the fore said vessels to the Peritonæum. & 1. The vessell of seed called deferens, or the Leading Vessell.

dle quantity and consistence in respect of the iuyces drawne by them both: but the reason of his smalnes is, because the number of his drawing orifices is both greater & more commodious then those of any other instrument whereby the liver is depurated or purged.

His Substance

The membrane.

The crust of the vesicle.

His substance is membranous, to the end that being full, it might be dilated or stretched, and when it is empty it might fall together againe. For it hath a double membrane; one common from the Peritonæum (Vesalius saith from the coate of the Liver) wanting Fibres wherewith that part onely which hangeth off from the Liver (which onely stands in neede of a defence) is cloathed; and with this coate it is tyed to the cavity or bosome of the Liver. Another proper, thin indeede, but firme and strong and of such a nature that it is not to be hurt or offended by choller, by which other membranes are much affected. Wherefore though it be but single, yet the number is supplied by the strength and fastnes of it; for it hath all kindes of fibres, that the substance might be stronger and fitter for dilatation; the inmost are right, the outward transverse, the middle oblique and those not many. It is within incompassed with a crusty substance ingendred of the excrements of the third concoction of the bladder it selfe, least it should be hurt by the acrimonie and sharpnes of the choler contained therein.

His

His Vessels are: Two slender veins from the trunk of the Gate veins, called *Cystica gemelle*, the twins of the bladder [Tab. 15. fig. 2. gg. Ta. 16. fig. 1. PP] which (as in the white coate of the eye) are distributed for his nourishment. For it is nourished as all other parts of the body with blood not with choller: & by other vessels [tab. 15. fig. 2. Q. Q. Tab. 16. fig. 1. DD. fig. 2. aaa] draweth his proper excrement pure and unmixed, faith *Galen* 5. *usu part.* 7. blended with blood, as doe the Kidneyes.

The arteries it hath are very small, from the Coeliacall artery which ascend [tab. 15. fig. 2. c. Tab. 16. fig. 1. N] vnto the hollownesse of the Liuer, that being (as it were) wrought by their continuall motion, it might be kept from corrupting.

A Nerue it hath, but scarce conspicuous or visible [tab. 15. fig. 2. f. Tab. 16. fig. 1. O] from a little branch of the sixth paire, that creepeth ouer the coate of the Liuer. All these vessels are fastned in the same place at the neck [tab. 15. fig. 2. b. Tab. 16. fig. 1. C] to the body of the bladder, and dispersed into his coate do reach vnto his bottome, [tab. 15. fig. 2. P. Tab. 16. fig. 1. A.]

The first Figure sheweth the Naturall scituation of the bladder of Gall taken out of the Liuer, his fashion and vessels.

The second Figure sheweth the bladder of Gall growing to the Liuer, but opened, that you may see his valves: it also sheweth the *Portus biliaris*, which passeth from the Liuer to the Duodenum.

TAB. XVI.

FIG. I.

FIG. II.

A I. The bottome of the bladder of Gall, in his naturall scituation.

B I. A bosome or denne at the beginning of the necke of the bladder, at which place within are the valves placed.

C I. The necke of the bladder of gall.

s 2. The out side of the bladder of gall.

t 2. The bosome or denne proper to the vesicle or bladder of gall.

u 2. The neck of the bladder.

v 2. Three veines at the necke, sometimes but two.

w 2. The *Portus biliaris* open, which carrieth the thicker choller directly from the Liuer, to the end of the gut *duodenum*.

x 2. The meeting of the necke of the bladder, and of the *Portus Biliaris* into one. aaa 2. Certaine small passages out of the bottome of the bladder, carrying the thinner part of the Choller into the Liuer.

The vessels.
The twin-
Veines.

Arteries.

Nerves.

It is divided into a bottome, a neck, and the passages of choler, which are called *Meatus* or *pori Biliarij*. The bottome is the greatest [table 15. Fig. 1. 2. P. tab 16. Fig. 1. A] part of the bladder, and looketh downward [as appeareth table 16. Fig. 1.] when with the Liuer it remaineth in his naturall seate. It is round, and dyed with the colour of the yellow choller it containeth; sometimes it is blacke, when the choller being long kept in the place is adust or burnt, which also now and then is condensed or hardned into smooth stones of diuers forms, which stopping the lower passages, we haue knowne to breede perpetuall laundises and incurable.

The necke.

The necke is the narrower part [table 16. Figure 2. b] of the bladder, much harder then the bottome, to whose end is set a peculiar bosome or cavity. [Table 16. Figure 1. b. Fig. 2. f.]

The figure.

It is also long, looking vpward, and by degrees ending in a narrow passage [table 16. fig. 1. C] which making a semi-circular Figure, as of a halfe Moone, determineth into the passage of choller, called *Porus* [tab. 16. Fig. 1. H] *Biliaris*, where the common passage is made [table 16. Figure 1. I.]

The passages of it.

The passages of the bladder of gall are double (called *ποροι χοληδόχοι*, because they carry choler) for that the cholericke excrement is two wayes purged out of the liuer, to wit, pure and vnmixed, or mingled and thicke according to *Galen*, 4. *usu part.* 12, and 13. For the vnmixed and pure choler is drawne by small vessels [tab. 15. Fig. 2. 22, tab. 16. fig. 1. DDD, Fig. 2. aaa] sent into the Liuer [tab. 16. fig. 2.] with infinite strings: shed abroad betwene the rootes of the hollow [tab. 15. fig. 2. S. tab. 16. L] and gate veines, [tab. 15. fig. 2. R. tab. 16. fig. 1. F] and at the length ioyned together into one [tab. 15. figure 2. b a. table 16. figure 1. E] passage, and thence powred into the bladder, and it is continually filled and as continually emptied (the bladder being pressed as some say in those creatures that go vpright by the Liuer, in others by the stomacke) by a passage [table 15. figure 2. b. table 16. figure 1. G] determining into the pore or hole of choler, [table 15. figure 2. C. table 16. figure 1. I] which is very fine and threddy, that it will scarce admit a Probe, especially where there are certaine small Membranes about the necke [tab. 16. figure 2. X] which hinder the recoyling or regurgitation of the choler.

The way of the mixed choler.

The thicke and mixed cholericke excrement is drawne from the Liuer by another passage called *Porus Biliaris* [Table 15. Figure 1. 2. C. table 16. figure 1. H, figure 2. Y T] the pore or hole of choler, supported by the inferior membrane of the *omentum* or *Kall*. This is a long vessell, which from the liuer is inserted in a circular or round figure not into the bottome of the stomacke, least the choler with his biting sharpnesse, should prouoke the stomack to put ouer the Chylus before it were concocted, nor into the seat or place of seidge, not so much for feare least in so long a passage it should be broke; as because this excrement being powred forth into the small guts (for this passage being stopped men become full of laundise, and their excrements white) attenuateth and cutteth a great quantitie of Flegme cuer heaped vp in them, scoureth their inward superficies, and being mingled with the excrements gathered in the great guts, doth prouoke them to excretion, that so together with the dry excrements it may be auoyded by the stooles. But this pore of choler is inserted into the small guts, not at their beginning, least the Choler should flye vp into the stomacke (although where there is plenty of it it vseth to regurgitate or recoyle to the stomacke, which is ordinary in cholericke natures when they fast long) but into the end of the *Duodenum* at the entrance [table 15. fig. 2. D. tab. 16. fig. 1. M] of the *teinum* or empty gut betwixt the two coats of the gut, obliquely, the orifice being couered with loose membranes or rather with the foulds of the inmost coate straightly ioyned and closing vp the passage least any thing should returne back, much like the passage of the water into the bladder. Sometimes the pore is parted in twaine, with a small distance betwene the partitions and both of them inserted into the same gut. And it carrieth mingled choler together with more pure, to stirre vp the faculty of the guts to auoyde the excrement after the Chylus is sucked from them.

A third passage not perpetually found

There is also found sometimes a third passage, inserted into the bottom of the stomack, into which it powreth choller; and such men doe continually vomit choler, and are called *πυρροχολοι ἀνω*, that is, purgers of choller vpward, as those men who haue it at the end of the empty gut, are called *πυρροχολοι κάτω*, that is, purgers of choller downward, and these mens stooles are alwayes bilious. The vse of this bladder of gall is to receiue and expell yellow choler

The vse.

choller exactly sincere vnmixt and familiar into it selfe immediately from the Liver and so out of the whole body, which other wise running at randon through all, would defile the spirits, raise a continuall vlcereous sence his acrimony gnawing the flesh and rending the membranes, cause all our motions to be head-strong and giddy, our sensations phrenetick and mad; and beside diuerse other inconueniences would breed a continuall laundise.

CHAP. XIII.

Of the Kidneyes.

THe Kidneyes are called *Renes* of a word which signifieth to flow, because the vrine flows away by them; and *νεφροί* as it were Pissers. All men and foure-footed beasts which beget by generation haue them, but no fowle or fish with scales, saue onely the Torroise, saith *Aristotle* in his 4. book *de partibus animalium*; for their humour is spent into scales and feathers, and beside they drink little because their longues are not so bloody

The lower Belly emptied of the Membranes, Guttes, and Stomacke, together with many of the vessels which are therein.

TABVLA. XVII.

yet is it very necessary as long as the nourishment is contained in the veins of the mesentery and the Liuer, that by the thinnesse of this humour or whay being made fluxible, it might passe those straight veines, whereupon *Hippocrates* called it *vehiculum alimenti*, or the wester of the nourishment, as before is said. But when the bloud is gotten into the hollow vein, it then needeth not so much helpe, because it is to passe through large and patent passages, and, beside is made of it selfe more fluxible by the heat of the heart and the liuer.

Why placed
one above
another.

Their positio.

An vncouth
forme of the
Kidneyes ob-
serued by *Bau-*
hine. An. 1589

They often stand not one opposite to the other [*Tab. 20. and tab. 2. lib. 4.*] left in their ioynt strife they should hinder one the others attraction, as *Galen* hath conceiued; but we, sayeth *Bauhine*, imagine that the cause of this position is rather to be attributed to the arising of the vessels [*Tab. 20. b.*] and properly of the emulgent or sucking veines, because their attraction is greater and of more vse. They lie with their f. sides vpon the muscles of the loynes which they call *Ios*, appointed for the bending of the leg; about their heads not much lower then the lowest ribs, in those voyde spaces which are betwixt the rootes of the ribs and the hip-bones. They lie betweene the two membranes of the *Peritoneum*, one of which lyeth vnder them, the other vpon them; whence it is that in fits of the stone, the leg on that side where the stone lieth is benumbed, sayeth *Hippocrates*, because of the compression as well of the muscle we spake of before, as of a sinew which descendeth that way.

But before we proceede further in the particular description of the Kidneyes, giue mee leaue to insert a story out of *Bauhine*, wherein he describeth a strange fashion and position of a kydney, with all the vessels thereto belonging; which we haue caused also to be cut in the following Table for thy better satisfaction, gentle Reader. In our publique Anatomy saith he, *Anno Dom. 1589.* we found a very vncouth forme and scituation of a left Kidney, as also of the emulgent and spermaticall vessels: For the Kidney was placed iust vpon the diuision of the great Artery and hollow veine at the *os Sacrum* or holy-bone [*Tab. 18. d e*] in that cavity wherein the bladder marked with [*f*] was scituated; but in the Table we haue removed the Kidney a little from his place, that the implantation of the emulgent vessels might better be demonstrated: for there were three emulgent veines, & two arteries fastned into it. Two of these veines proceeding out of the middest of the trunk of the hollow veine [*tab. 18. 6. 6*] and descending directly downeward, were implanted into the right side. The third emulgent arising out of the left side [*tab. 18. 9.*] of the hollow veine, and descending vnder the trunk of the great artery, was a little mixed with the left spermaticall vein [*tab. 18. 16.*] and after inserted into the left side of the Kidney.

As for the emulgent arteries, one of them had his beginning vnder the bifurcation, out of the right Iliacall branch [*tab. 18. 7.*] The other did arise a little about the bifurcation out of the great artery; [*tab. 18. 8.*] the first was simple and inserted into the right side of the Kidney; the second was diuided into many branches and did insinuate it selfe into the left side. So also the left vreter was very short, arising out of the lower end of the kidney, [*tab. 18. 19*] and was inserted into the bladder [*Tab. 18. 20*].

Finally, in that place where the left Kidney is vsually placed, Nature had set a glandulous and fat substance [*tab. 18. c*] to which both an emulgent veine and artery were disposed [*tab. 18. 4. 5.*] as also from the vpper emulgent veine, the left spermaticall veine [*Tab. 18. 4.*] did arise. It may be that those men who are by fits tormented with grievous paines about the Holy-bone, and haue all the *Nephreticall* signes, haue such a position of one of their kidneys as this was: now we returne to our description.

The seate of
the right kid-
ney.

Of the left.

The true causes
of their diuers
position.

The right Kidney lieth iust vnder the Liuer, and because of his waight in a man [*tab. 18*] it is lower then the other Kidney, as if it gaue place to his better; his end reacheth to the third racke-bone of the loynes. It is very rarely higher then the left, and then onely when it is shorter, or when the part of the Liuer lying next it, is hollowed: they are also rarely of an equall height, because of the different position and quantity of the Liuer and Spleene; some also adde because of the higher or lower beginning of the emulgent vessels.

On the left side, the Kidney lyeth vnder the Spleene, and is often (yet not alwayes) higher then the other, because there the Spleene is thin and slender; so that the Kidney ascendeth sometimes to the first racke-bone of the loynes, sometimes to the 11. of the breast, yet neuer is one so farre above the other, that the middle of the higher doth reach about the top of the lower. But in brute beasts because of their groueling gate, and because their Spleen reacheth further downeward, the scituation of the Kidneyes is contrary, so that in Dogges there is a hollownesse or bosome made in the Liuer (which in a man hath neither hollownesse nor diuision) that the right Kidney might ascend higher. Indeepe the true causes of their

their diuerse scituation, are the different magnitude of the kidneyes, the different length of the vessels, and their position either more or lesse oblique. They are knit by the help of an externall Membrane arising from the Rim (which like a ligament stayeth them firme-^{Their connexion.}

ly in their proper places) to the loyns, the *Diaphragma*, and the right to the blind gut, sometimes to the liuer; the left to the *Colon* (whence it is that nephreticall paines, that is, inflammations or other paines of the Kidneyes, become more grievous by reason of abundance of wind or excrements, and the collicke is often hardly distinguished from the paines of the Kidneyes) and to the spleene.

Their fibres.

Beside the membrane aboue named, they haue also other fibres from the *Peritoneum* inserted into their gibbous part, which are happely those *Hippocrates* calleth Nerues, in his Booke *de natura ossium*. They are also tyed by the emulgent vessels to the hollow veine and the great Artery [tab. 17. ab, table 2. Lib. 4. m n, tab. 22. bi.] Finally to the bladder it selfe by the vreters or passages of vrine, of which we shall heare more by and by [table 17. p c d, table 22. m n e.]

Why two.

The Kidneyes are two, because one would not haue beene sufficient for the euacuating of so great a quantity of waterish excrement, which is fare more abundant then both the excrementitious chollers, yellow and blacke. By this meanes also there is a stronger attraction of serous blood, and both sides draw alike; and if one happen to be stopped with the stone or grauell or ought else, yet the work of attraction standeth not, but the vrine is auoided; (although *Archangelus* will not yeelde to this, because Nature hath created nothing against casualties,) whereas if there should be but one (which is very rare) it must haue beene of necessity as big as both, because of the abundance of this excrement, and so the body should not haue beene equally ballanced, vnlesse that one had beene seated in the very midst of the backe, iust vpon the hollow veine and great Artery, which scituation would haue hindered the free descent of blood and spirits by compression. Wherefor Nature for one greater made two smaller, that neither the belly should bunch out, or the creature incline and hang too much to either side. It is also as rare to see three or foure, which when it hapneth they keepe not their ordinary conformation. *Eustachius* obserued three together, the right was naturall, the left had nothing like a Kidney, but onely the substance of a triangular forme, and wanting an vreter, for the vreter proceeded out of the third which was almost foure square.

The figure.

The Figure of the Kidney is long and broad, yet broader aboue then below; before and behinde pressed somewhat flat, yet a little more rising before like a bean which thereupon we call a Kidney beane. On the outside (which they call the backe [tab. 22. Fig. 1. c.] of the Kidney) toward the flankes gibbous or embowed and round: on the inside where they looke toward the hollow veine, partly gibbous and partly concavous, flatte or sadled, and as it were crooked into the forme of a line turned with a blunt angle, for such must it of necessity be, both for the admission of the vessels, and for the forming of the hollownes or caviities therein.

The magnitude of the kidneyes.

Their magnitude is proportionable to their office of purging the whaeye humour, although for the most part they are not of a like [tab. 22. Fig. 1.] bignesse, nor their proportion answerable to the body; yet the greatest disproportion is in their longitude, which commonly equalleth foure rack-bones, but their breadth for the most part is but of three fingers, and the left is often shorter then the right.

The fat of the kidneyes.

About the kidneyes cleaueth fat plentifully [tab. 2. Lib. 4. oo pp] because it hath peculiar vessels by which it is nourished; so that in fat men they are almost all couered: the vse of which is to cherish the heate of the Kidneyes, lest by reason of the continuall distillation of so great quantity of the vrine or whay, the heate by degrees languishing might at length be extinguished, and so all their action faile; and beside, lest the vessels should be endangered by distention; wherefore in a man it is on the inner side of the Kidney layd as a soft bed or couch betweene the membrane compassing about the distribution of the vessels and the branches of the vreters: in a Dogge betwixt the membrane which formeth the saddle side of the Kidney; besides, this fat with his smooth and slippery moysture dulleth the acrimony of the whay or vrine.

The vse of it.

There cleaueth to both the Kidneyes in the vpper part, where it regardeth the hollow veine, a glandule or kernell, the inuention or finding whereof is due to *Eustachius*, which sticketh fast to their outward membranes, so that oftentimes if a man take not heede in the taking out of the Kidneyes, he shall leaue it hanging to the Membrane of the *Diaphragma*. This glandule somewhat answereth in substance and figure to the Kidneyes themselues, yet is often more flat and liker to a cake then to a kidney; as long it is as two fingers, as broad as one, of a moderate thicknesse; but they are not alwayes of an equall greatnes, but most

The glandule of the kidney.

com-

commonly the right is the larger. Among the new writers (some say) there are manie of them, but will not haue them to be found in euery body, but to bee engendred when the matter is too plentifull; but how soeuer we haue the things, yet hitherto we want their vse or at least the knowledge thereof.

The vse of these Glandules not yet knowne.

To this Glandule there is sometime sent a certaine Tendril from the hollow veine neere the Liuer, sometimes it taketh it from the Veine which we call *Adiposa*, which goeth to the fat of the Kidneyes to nourish it, of which wee spake euen now: sometimes it hath both Veines.

Table 19. sheweth the Kidney of a man. The first figure the whole Kidney; with the Glandule set a-boue it. The second Figure sheweth the Kidney Dissected, that you may see the inward face of it.

TABVLA XIX.

FIG. I

A 1. The Kidney of a man whole.

B 1, The Glandule placed vpon the Kidney.

C 1, The emulgent veine and Artery.

D 1, 2. The Vreter.

ccc 2. The Vreter open, and how it parteth it selfe into the substance of the Kidneyes, as it were with many pipes.

FIG. II.

fff 2. Caruncles or teats, with very fine perforations, which opening into the foresaide pipes of the Vreter, doe as it were through a fine strainer passe the Vrine into them, to bee conueyed to the bladder.

The Kidnies are couered with a double Membrane, one outward arising from the *Peritoneum* neere the lower part of the *Diaphragma*, where it is knit vnto the *Peritoneum*: this cleaueth not very straightly to them [tab. 2. lib. 4. OO, PP] but they are as it were wrapped in it, whence it is called *fascia renum*, that is, the Kidneyes swathing band. This Membrane receyeth the *vena adiposa*, [table 17. XT, table 2. lib. 4. lb] and is rowled in plentifull fat, and so serueth the Kidneyes instead of a couering, of a tye, and of a soft pillow or bolster.

The Membranes.

The other Membrane which is proper to the Kidnies is very thin, and produced out of the common coate that compasseth the vessels (but dilated) and growes to them exceeding strongly, so that it maketh their flesh otherwise of it selfe firme, yet more fast and compact, And although it make the outside glib and shining, yet it wanteth fat, neyther is it wouen with any vessels. This accompanieth the vessels, bent inward it pierceth into their hollownesse, and compassing them round about, makes them more strong.

The substance of the Kidnies [table 21. Figure 2] is a hard flesh most like the heart, fauouring that it wanteth fibres, which yet the threds of the veines do supply. Fast and compact that the inherent heate may more strongly and easily draw the vrine that is so neere (for to draw an excrement from farre, a loose and lax instrument is more meete) and expell it; and againe, leaue the blood which is their nourishment should slippe away with the vrine, which would come to passe if their flesh had beene immoderately loose, whereas now it is

Their substance.

fitly

fitly reteyned, and hath time to bee diffused all ouer their substance. But on eyther side at the hollownesse [Table 22, e e] where the emulgent vessels are divided into greater braunches, their substance is but loose and vnequall, and is on the inside perforated with passages running through it from the vreters, where are obserued certaine parts rising somewhat from the flesh, which in their substance, figure and office do imitate the nature of glandules or kernels, whence some of the ancients haue esteemed these parts of the kidneyes to bee Glandules. Without, his superficies or face is like the Liuer smooth and glib: his colour duskish in a mans health, and not much vnlike a red Beane (seldome very red) and shining. It is also very rare that a mans kidneyes should be outwardly vnequal, and made as it were of many kidneyes or small glandules like the Liuer of a Beare or Oxe, yet *Eustathius* found

TABVLA XXI.

Fig. 1. sheweth the fore side of the right Kidney.

Fig. 2. sheweth the back side.

- a The body of the Kidney, consisting of eight lobes or partitions.
- b The Vreter distended with Vrine.
- c The emulgent vessels.
- d The lower part of the Vreter, far narrower then it vseth to be.

This Table sheweth the figure of a Childs Kidney, which died the fourth day after it was borne, in the Hospitall of *Argentine*. The child was opened by Doctor *Iohannes Rodolphus Saltzmanus*. He did indeede sucke, but auoided nothing either by stoole or Vrine. His guts were full of winde, but his Fundament was not perforated. His kidneyes were by lines distinguished into eight parts. His vreters wel stretched with water, but at the bladder they were so smal that a smal probe could hardly without violence be entred into them, which being stuffed with slime, did stop the descent of the Vrine, so that in the bladder, there was nothing but a little of that slime: the kidneyes were somewhat like the kidneyes of an Ox.

FIG. I.

FIG. II.

It shall not be impertinent also, to annex this strange forme of the kidneyes which *Bauhine* receiued from that excellent Philosopher and Physitian, D: *Leonard Doldius*, the ordinary Physitian of the City of *Norinberge*. This kinde of Kidnie and Vreters was obserued in the body of *Andrew Helme* of *Weissenfeld*, who dyed at *Norinberge*, the 17. of October, in the yeare of our Redemption, 1602. and the sixteenth of his life, hauing lyen long hurt of a blow he receyued in his belly about the groyne.

such

such in two Infants, a Maide of a 11. yeares of age, and a Man at Rome. The forme of a kidney of that kind discovered in a young Childe by Doctor *Saltzmanus*, and by him sent vnto *Basilius*, we haue here a little before annexed.

They haue two *venters* or cauities, the outward and inward: the outward improperly so called [Table 22. d] which *Fallopian* calleth the Gate, is in the saddle side, where the kidney being like a bent bow returned at either end, it is most what diuided into three parts. The first is a bunch or prominence like a smal hillocke, at either end of which there is a bosome or cauity ending in another prominence before you come to their gibbous part. Into the corners of these bosomes the diuided vessells [Table 22. l b] doe offer themselves, thence to be dispersed into the substance of the kidneyes, one branch into the vpper angle of one bosome, another into the lower angle of the other, out of which also the *ureter* proceedeth.

The cauities
of the kidney.

The vessells which are sent vnto the kidneyes are of all sorts, Veines, Arteries & Nerues. The Veines proceede out of the hollow veine one of them [table 17. x r] is that fatty vein whereof we haue spoken, and it is double; one on the right hand, and another on the left: The right issueth very rarely out of the trunk of the hollow veine, but most what out of the emulgent; the left alwayes out of the hollow veine, and is diuersly distributed to his vtter coate to water or bedew the same; sometimes also it offers a little branch to the glandule which we spake of adioyned to the kidney, which when it hath perforated it is againe consumed in this coate of the kidney.

The vessells,
Veines
Vena adiposa.

The other veine, of his office is called the emulgent or sucker [table 17. a b, table 22. h i] most commonly one on each side; for in the framing of these vessells Nature often diuersly disports her selfe, so that they differ oftentimes not onely in seuerall bodies, but euen in the same. This Emulgent is a notable vessell, and the greatest of all that arise out of the hollow veine; not that the Kidneyes stand in neede of so great store of nourishment, but that the serous blood may haue a free and expedite passage. It ariseth seldom directly out of the trunk of the hollow vein, but is carried with an oblique but short progresse downward, and being parted into 2. branches, is inserted into the saddle side of the Kidney, carrying thither the serous or watery blood out of the hollow veine. In these emulgents wee haue obserued certaine valves or floud-gates which hinder the recourse of the whay or vaine into the hollow veine. With these is vnited a branch one or two of the veine *sine pari* or without his fellow, (of which we shall entreate more fitly in another place) that there might be a consent betweene the Kidneyes and the breast.

The Emulgent
veines.

Why the Emulgent
is so great.
Whence the
Emulgent arises.
The values of
the Emulgents.

Arteries it hath of each side one [table 17. vnder a b, table 22. vnder h i, table 18. character 3, 5.] from the trunk of the great Arterie; great emulgents or suckers also, which do purge waterish moysture (plentifully containd in the Arteries) from the blood, and withall doe allow heate to overcome the cold of the Kidneyes, which *Galen* sayth they acquire by the passage of the watery moysture through them.

The arteries
of the kidneyes.

Their use.

These vessells first parted into two, do then get into the cauities of the Reynes and are presently diuided, commonly into foure braunches, and so are disseminated diuersly into the whole substance of the Kidneyes [table 21. Figure 1, G G] till at length they are so by degrees seuered by manifold partitions, that they become as small as hayres: then they approach vnto the Caruncles which are *spongy* peeces of flesh, through which the whay is filtered or streyned.

The Kidneyes needed no other third veine differing from these whereby they should be nourished, because they doe not draw a pure excrement as the bladders doe, which therefore needed particular veines to carry their nourishment; but these vessells being full of blood as well as of whay, doe nourish the kidneyes with the blood, and send away the whay to be auoyded. They haue nerues on either side from the stomachicall branch of the sixth paire (whence comes the great consent betweene the stomacke and the kidneyes, and the subuersion of the stomacke, and frequent vomits in Nephriticall passions or diseases of the kidneyes) which descend downward to the rootes of the spondelles or racke-bones of the loynes; and are distributed into the proper membrane of the kidneyes. Moreouer from about the originall of the Arteries of the mesenterie, there doe proceede a fewe tendrils of sinewes mingled together; part of which goe vnto the kidneyes and the glandules that lye vpon them, the other part together with the emulgent Arteries doe insinuate themselves into the hollownesse of the kidney, and are distributed through their substance. Hence it is that Nephriticall patients haue not onely a certaine dull sence of paine, but also most vehement

Why the kidneyes
haue no particular
veins to nourish them.
The nerues of
the kidneyes.

hement torments in their kidneyes; not onely therefore because their holes or denues, as *Galen* sayth, are not wide but narrow, & the kidneyes because of the firmenes of their substance cannot be stretched as the bladder may, but especially because of these nerves distributed through their substance; notwithstanding the paine of the stone is greater when it entreth into the vreter, both because of his exquisite sence, as also because of the straightnes of the passage through which the stone falling, must needs teare it almost with stretching, which paine wee see not alwayes to follow those whose passages are dilated by the often coming downe of stones.

The inner
venter of the
kidneys,

The inner venter or cauitie of the kidney, hath a hollownesse made of a sinewey membrane which the emulgent vesselles doe not produce, for they determine into exceeding hairy threds; but the vreters, which becomming first broad in the hollownesse [table 21. Figure 1. F] of the kidneyes are the matter of it. At whose side on either part before the vessells are diuided into lesse branches, the substance of the kidneyes appeareth loose and vnequall (the Anatomists call it *Cavernosa, spongi-formis, erosa*) when the fat that compasseth it about is diligently removed.

The Vreters,

The vreters are diuided into great branches, first double or treble (as in the next chapter shall appeare) and then into many others, not (after the manner of other vesselles) still lessened into hairie threds, but broad in the end (so that a man may obserue eight or ten branches like canels or pipes) that they may better receiue the Caruncles before spoken of. For those Caruncles which are like small glandules in the endes of all the vessells (and of a paler colour because they are of a harder flesh then the rest of the kidney) being produced out of the substance of the kidney, and somewhat sharpe like vnto the nipples of breasts, insinuating themselues into the said vessells in manner of a couer or stopple, doe stoppe them vp; which if they be cut according to their length, a man may obserue in them certain furrowes and tunnelles as small as hayres. Wherefore, being so finely bored that they will scarcely admit a haire; by them the whay or serous humour coloured with choler, is separated from the blood, and is insensiblie percolated or drayned into the pipes of the vreters or membranous tunnels (this is called the *Colatorie*) and gathered together in that common hollownesse, and thence is sent downward by vreters into the bladder: it may bee these furrowie passages are hollowed in the substance of the kidney like as the holes in the nipples of the breasts. And these spongie Caruncles had neede to be so finely bored, least the blood which together with the vrine and choler is drawne by the emulgents but for their proper nourishment, should with them also passe away into the bladder (which we see sometimes to happen and that without paine; when either the separating or reteyning vertues of the kidneyes are decayed or those small passages widened) considering that this separation is made not by concoction where Nature is her owne chooser, but by transfusion; although wee doe not deny but that these excrements do here receiue a kinde of elaboration though not a concoction.

The colatorie

The separation of the
whay is by
transfusion
not by concoction.

How the kidneys are nourished.

This blood thus remayning behind, is as it were sucked by the flesh of the kidneyes, and is sprinkled vpon it like a kinde of dew; from whence by degrees after the manner of a vapour it is scattered into his whole body, cleaueth, is vnited to it, and finally becommeth the nourishment of the kidneyes. But because being so thin it nourisheth but slenderly, it is continually and in great quantity drawne in, together with much vrine, which (the blood remaining behinde) insensiblie droppeth through those Caruncles.

The triall of
the truth in
this discourse
of the passage
of the vrine.

These things, although they differ from the common opinion of some others yet, may they fitly be demonstrated if you put a Probe into the vessells as they enter in, and the vreter as it goeth out, and then make incision at the saddle side of the kidney; and yet much better and more elegantly are these passages shewed, if you separate the flesh of the kidney from his vessells; which separation hath abundantly satisfied vs in this point: and therefore we haue exhibited it in the 21. Table and the first Figure.

But because these things doe not so appeare in Dogs as we haue now saide, and yet young Students for want of Mens bodies are often faine to dissect the kidneyes of Dogs: wee thought it not amisse, here briefly to insert the description of Dogs kidneyes also.

The structure therefore of a Dogges kidney delineated in the second Figure of this 21. Table is on this manuer.

The description
of a dogs
kidney.

The membrane immediately couering the kidney entreth into his cauity where it is reflected or returned and on both sides spread abroad, like as is the membranous bodie from which the Vreters do proceede. To this Membrane cleaueth the fat whereupon the dis-

stri-

Fig. 1. sheweth the vessels of the Kidneyes separated from the flesh. Fig. 2. sheweth the Kidnies Dissected according unto Vesalius. The first is the Kidney cut according to the length through the gibbous part, so as the slit reacheth unto the second sinus or cavity of it, no part of the kidney taken away. The second exhibiteth the Kidney where all the substance or partition which is called Septum renis is sliced away in a compasse, that the second cavity may better appeare.

The third sheweth all the branches of the first cavity or sinus, the flesh of the Kidney being quite taken away. Fig. 3. expresth the devise of some men concerning the percolation or streyning of the whey; the first sheweth the Kidney dissected from the gibbous part toward the Hollow part, together with the Cribrum or Sine, the second sheweth the middle part of the Kidney.

$\theta\theta$ 2. The backe part of this sinus is marked with η , the forepart with θ .

Fig. 3. The emulgent veine and artery.

B B. The sinus or cauitie into which the vrine is streyned out of the first cavity.

CC. The cavity into which some think the vessels do powre the serous or wheay blood,

DD. The substance of the kidney compassing this cavity round about.

EE. The Drain of the Kidney called Colatorium, or the Membrane perforated like a sieve, through which the vrine passeth say some, together with the Choler that coloreth it out of the cavity marked with B, into the cavity marked with C.

FF. The Vreter which receyueh the vrine out of the second Cavity, and leadeth it into the bladder.

distribution of the emulgents into the Kidnies doth leane, as vppon a pillow or boulder for their security. It hath also many holes through which the vessels enter into the Kidneyes. Next followeth that which is called *The membranous body*, which is diuided into manie branches and as a couer compasseth the vessels, it maketh a cavity which conteyneth the vessels and the fat.

Vpon this *Membranous body* lyeth the cavity of the Kidney, in the middest whereof hangeth a part of the substance of the Kidney regarding the gibbous side, differing in colour from the rest, and wanting the Membranous couer before named. It is like a new Moone, and hangeth like a partition, so leaning vpon the *Membranous body*, that the cavities of the same Kidney seemeth to be double. But in the Kidney of a man there are no such cavities to be found, but the emulgent vessels and the Vreters are diuided through his substance into many branches, and the cavities which are in the Kidneyes are wrought as it were out of them.

The vse of the
Kidneyes.

The vse of the Kidneyes is to draw from the whole masse of bloode, as well that of the Veines, as that of the Arteries, the serous humour through the emulgent vessels by a proper attractive faculty arising from the similitude of substance betweene it and the kidnies, and so to purge both kinds of the blood, arteriall and venall from that excrement. For those parts which through large orificies do draw their conuenient and familiar iuice, cannot draw it pure, simple and sincere, but with the admixtion of some other of a diuers kind. Wherefore together with the Vrine is drawne both much moyst and thin blood out of the Liuer, and much yellow choler, which the bladder of Gall did not attract before. But the Vrine or whey by the force of the kidneyes is segregated from the blood in the very concoction of their Aliment, & beside their attractive faculty gathereth the blood into their substance for the nourishment of it: but the Vrine as an vnprofitable excrement, the expelling vertue straineth through the furrowes or tunnels of the Caruncles (thorough which also the grauell passeth from the body of the Kidney together with the Vrine) into the membranous pipes of the Vreters: which vrine is gathered together in the greater hollownesse of the Vreters, and from them is sent into the bladder, where againe it is kept a certaine time, and at length is expelled thence at our discretion through the Yard, the Sphincter. Muscle being relaxed or loosened. The choler also passeth along with the vrine, from whence it hath his yellow tincture: for when the choler gaddeth vpward to the braine (as in phrenies it is not very rare) then are the vrines very pale.

How the v-
rines are colo-
red yellow w.

The common
opinion of the
way of the
vrine before
Vesalius time

Before *Vesalius* time it was a common receiued opinion, and reteyned yet by some, that in the Kidneyes there are two bosomes or cavities running according to their length; one higher, another lower, which are distinguished by a transuerse or ouerthwart Membrane perforated like a Siue which they call *Renis colatorium*; and that the emulgents did powre serous blood into the vpper cavity, and thence the choler and the vrine did passe through the fine searcing holes of the Membrane into the lower bosome; the blood remaining behinde because of his thicknesse. Out of the lower cavity yssueth the Vreter, which receyueh the streyned vrine, and conuaiteth it into the bladder. The manner of which deduction of the vrine we haue expressed in the third *Figure* of the 21. *Table*. Thus.

Vesalius opi-
nion.

The emulgent vessels which powre the serous blood into the first cavity at *A*. which is strained through *E*. into the lower cavity *C*. and then receiued by the Vreter which is marked with *F*. Afterward *Vesalius* (who counselleth to Dissect either a Dogges Kidneyes or a Goats, fearing to deale with a mans because of the fat) and almost all before *Fallopins*, were of opinion, that the Kidneyes had two cavities, the one wouen of the extremities or ends of the emulgents which passe into the kidnies. This texture is hollow like a Vessell, and is distributed through the body of the Kidney, and at length diuided into a forepart & a backe part, each of which produceth fixe, seauen, or more thick branches equally distant one from another, yet so that the fore-most are vnited with the hindmost in the out side where they make a circle, and so do agree together to make a cavity to receiue the serous blood. The other bosome or cavity is on the backe side, betwixt the branches of that *membranous body*. And this by the interposition of a part of the Kidney, is diuided into two parts, where it receyueh the whey distilling from the substance of the Kidney, and fendeth it into the Vreters. This cavity in Dissection is found moyst, but without bloode, but the former is alwayes found full of blood, and this conceite is answerable to the *Figure* of the Dogs kidneyes. [*Tab. 21, Fig. 2*] And thus much of the Kidneyes.

CHAP.

CHAP. XV.

Of the Vreters or passages of urine.

THE Vreters or urine leaders or vessels of Urine, the Greekes call *uplūpas*, as a man should say the pissers. *Hippocrates de Glandulis* calleth them *oxetis* or conduit pipes. They are two vessels [Table 27, c. d. Table 2. lib. 4. qq. Tab. 22. mm] on cyther side one (sometimes, but seldome two or more, yet meeting in one before their insertion) which lying vpon the Muscles of the Loynes, and a little inflected or turned inward to make an oblique passage, doe descend betwixt the two Membranes of the *Peritoneum* or *rimme* of the belly vnto which they are knit, and soare ioyned to the bladder. [Table 22. f. Table 16, char. 18, 20.]

Their figure is round, a palme; long and of the bredth of a straw; in those that are much troubled with the stone dilated to the proportion of a chickens gut; hollow and running aside or obliquely like the letter *f*. In women larger then in men, but right and short, and hence it is that they auoide stones with much lesse pain then men. Their substance is properly white (whence some call them the *white veines*) without blood thicke and neruous, (whereupon other men call them *neruosi canaliculi* or the neruous Tunnels) which makes them so strong.

Table 22. sheweth the Kidneyes with the vessels of urine and of seede; a part of the Hollow veine and of the great Arterie, the Testicles, the bladder, and the yard. The first figure sheweth the fore-side, the second the hinder side.

The proper
coate of the
veffels
Their diuani-
cation in the
kidneyes.

This kinde of substance is found in no other part of the bodie vnlesse it be in the bladder, to whose inward substance they are verie like, and to which they are continuat; by reason of which substance, & beside, because they may not be seuered frō the bladder without breaking (whereas they may from the kidneyes whole and sound) it may be lawfull to say, that they haue their original from the bladder, although our great Ancients, *Hippocrates*, *Aristotle* and *Galen* haue taught otherwise, namely, that they arise from the Cautie of the kidneyes. This substance, gifted with oblique fibres for distinction sake, if any man will say is the proper and peculiar coate of the vessel, which a common membrane doth inuest, giuen him for further strength from the *peritonaeum*, we will not gaine say him.

But these vreters after they haue incompassed [Table 21. Fig. 1.] the inward venter or cautie of the kidnie and made 8. or 10. pipes, they passe out at the saddle side, or if you will rather say thus, when the vreter is gone into the kidnie (of a man not of a dog) becomming somewhat broader, it is diuided into three branches like the emulgents, and is distributed into the vpper, the lower, and the middle region of the kidnie, of which the vpper and lower are againe subdiuided each of them into 3. and the middle into two; these being short and large haue broad ends, wherein euerie one of them receiue the glandule which we said was like the nipple of a womans breast, arising out of the flesh of the kidneyes in the manner of a fleshie stopple, that so through them the vrine might be streined into euery one of the pipes or runnels. Often times many of these braunches are perforated in the middle likewise, where in their vtter mouthes they receiue a glandule also.

Their implan-
tation into
the bladder.

The reason of
this implanta-
tion.

They are implanted into the backward and lowest part [tab. 22. 4.] of the bladder (for their implantation could not be more commodious because the bladder cleaueth to the right gut) not farre from the neck betwixt his two proper membranes hauing the distance of two fingers betweene them, and so with an oblique insertion they pierce the cautie of the bladder, but their passage or entrance is very narrow; by which kind of insertion the returne of the vrine toward the kidneyes againe is foreletted. Some ascribe this hinderance of the reflux of the vrine to certaine transuerse membranes like vnto valves, or the *small membranes of chaffe or husks of corne*, or like the leather latches of bellows, little differing from the substance of the bladder and placed vpon the insertions of the vreters, whose office also it is to giue place to the vrine when it flowes into the bladder and to hinder it from returning, either when the bladder is distended or in the compression of the belly, by stopping the orifices of the vreters; and trulie those orificies are so close shut vp, that when childre blow a hogs bladder and tie it freight at the neck, not so much as the aire can be pressed out. Wherefore *Galen* speaking of these passages, breaketh out into admiration of the wisdom and providence of our Creator, whereof he taketh this (and iustly too) to be a great document or argument.

In 6. Epid.
Com. 5. lib. 4.

Their vessels.

Their vessels are very hairie and fine, their veines and arteries they haue from the neighbor parts. Their nerues from the sixt paire or coniugation and from the marrow of the loynes, whence comes their exquisite sense and so exquisite paine when either the stone is in the head of them or passeth away by the flanks.

The vse of the
vreters.

Their vse is, that in their channels the vrine together with a chollericke excrement seuered from the blood by the power of the kidneyes, might passe into the bladder which is far distant from them and placed as a cisterne in the lowest part of the *Abdomen*, they are also thought to giue to the vrine a kinde of alteration, but more manifest it is that they do good seruice in freeing the kidneyes from the burden of grauell, or of the stone to which all ages and sexes are very prone and subiect.

CHAP. XVI. Of the Blader.

The bladder.

The bladder of vrine called in Greeke *κυσίς*, of a word that signifieth to hide, because it hideth the vrine, is seated in the *hypogastrium*, which therefore we cal the water-course, in that hollownes [Table 6. lib. 2. H. Tab. 2. g. tab. 2. lib. 4. Y.] which is made by the holy bone, the hip bones & the share bones meeting together, all which cautie is taken vp by the bladder (for it is a large cistern or vessell) and the right gut, close to which the necke of the bladder lieth connected or fastened. In women the bladder lieth betweene the womb [ta. 6. li. 4. T. sheweth the bladder, L. the womb, but ta. 27. of this booke shewes the bladder & the

The scituatiō.

p the womb] & the share bone, as wel because the draining vessels for the excrements of aliment are most conveniently placed in the lower parts for their easier euacuation, as also because of the entrails serving for nourishment, that those which are the most noble might have the vpper place. These bones also are ordained for defence of a part so verie necessarie, and of so exquisite sense, albeit the cavity which they make, was made for other vses, of which wee shall heare more hereafter. His seate is betweene the two coates of the *Peritonaeum* which make as it were a particular *venter* (whence haply it was that *Diocles* diuided the bodie into the head, the chest, the belly, and the bladder) vnder the Sharebone when it is empty; and in Dissection it can scarcely bee found at the first view, for it exceedeth not the greatnes of a reasonable peare, but when it is full it is stretched out into the hollownesse of the very belly, and may be felt about the groine.

Between the
two coates of
the *Peritonaeum*.
Diocles.

The bottome and the fore-part are tyed to the *Peritonaeum*, [table 6, Lib. 2, I. table 2.*] but loosely by two ties. The first is a Ligament [table 6, Lib. 2, b. table 2, I. table 23. Fig. 7. 8. 22.] originally arising from [table 23. Fig. 7. 8. Q.] his bottome and carried to the navill, [table 23. Fig. 7. 8. r.] which they call *Frachus* in the infant. And this ligament is fastened to the middle of the bladder. The other tie is of two vmbilical [tab. 6, lib. 2. a d, tab. 2. k l, tab. 23. Fig. 7. 8. x.] arteries dried, that when a man goes vpright, it might not fall vpon his owne necke and so hinder his excretion. In dogges the bottome of it groweth not to the *Peritonaeum*, but hangeth by a certaine proesse, moreouer in them it is very white, smoth at the bottome and slipperie, as it is also on the inside [tab. 22. Fig. 1. e.] and lined ouer with a phlegmatike humour.

The connection.

His figure is long, a little round, [tab. 22. fig. 3, 7, 8. fig. 2, e, 14. 23. Q.] which some haue likened to a sphere, some to a gourd; for if it were round as a bowle is round, it would be too much pressed by the parts that lie about it. It is hollow that it might receiue a great quantitie of liquor & from a large bottom by degrees growing narrower it endeth in a streight neck; wherfore the parts of the bladder, are two, the body and the necke. The substance of it is partly membranous or neruous, both for the more commodious extension because it is often to be filled & to containe the vrine, that we might not always be constrained, but within conuenient time to yeeld it forth; and also for his corrugation or knitting vp together after euacuation; Partly also the substance is fleshie. It hath three membranes, one common and two proper. The common is the vtter and is from the *Peritonaeum*, a strong and thicke one wherewith it is couered ouer and strengthened, that though it be distended with abundance of water it should not be broken or rent: by this also it is tyed in men to the right gut, and in women to the necke [Tab. 27. f, is the necke of the bladder annexed vnto the necke of the wombe about the priuities at u; tab. 8. lib. 4. Fig. 1. o. the neck of the bladder, and Fig. 3. e. the necke of the bladder, and d the neck of the wombe] of the matrix or wombe, and to the bones of the hippes which are next vnto it.

The figure.

The parts of
the bladder.
The substance

The membranes 3.
One common

The two proper membranes ioyned together are now thicker now thinner, as they are distended or angustated or streightned; but in the vppermost part of the bottome and about the necke because of the insertion of the vreters they are harder and thicker. The inner of these is transparent, very white, thinne, neruous, wouen exceeding thicke with all kind of neruous fibres, as also are all other membranes which stand in neede to be much distended and contracted. The right fibres are inmost, the transuerse outmost, the oblique in the middle according to the order of the functions, that is to say, of attraction, retention & expulsion; which were ordayned for the better conteyning and expelling of the vrine.

Two proper.

The fibres of
the inner
membrane.

This inner membrane (if the bladder be a little blowne) may be separated from the vtter. But that this fine membrane should not be hurt by the acrimonie of the vrine, because it is of exquisite sense, the inner cauitie of his bottome is rugous and full of folds and plights, and mucous or slimie, (some say this slime is a kind of *Fibrous* substance) or rather it is defended with a crusty coate engendered of the excrements of the third concoction of the bladder. The vtter of the proper membranes is thicker sprinkled with fleshy fibres, yet not red as are the fibres in the muscles, but whitish such as appeare in the coates of the stomacke, and the guts: such they seeme because they are placed betweene white membranes: although sometimes by affluxio or affluence of blood they become rednesse so conspicuous, that a man would say it were a fleshy membrane.

The vse of the
fibres.

It hath these fibres as well for the preseruacion of the heate which otherwise would bee very weake; as to keepe also the vrine from falling by the fibres of the inner membranes much distended in repletion: so that these fibres being contracted or drawn toward their

their originall by like little Muscles; by strengthening the bladder (which by the helpe of these fibres knits it selfe together) makes it more able to exclude or shut out euen the least thinges conteyned therein.

The passage.

It hath three holes or perforated passages, two in the backward and lower part a little before it end in the necke, where is the insertion of the Vreters [Tab. 22. Figure 1, 4, Tab. 8, Fig. 1, H] betwixt the two proper coates, by which the Vrine driven downe from the kidneyes, is of it owne accord powred into it, not by resudation or sweating through, but by open passages, [Tab. 8. lib. 4. fig. 1 M] To which (that the Vrine might not recoile or flow backe, no nor the very winde when the bladder is distended) beside the oblique insertion

Tab. 23. demonstrateth the Muscles of the yard, of the Fundament and of the Bladder, and the three bodies of the yard.

The first and second Figures shew the yard excoriated, cleaning yet to the bottome of the share bone.

The third sheweth the same separated with his Vessels.

The fourth and fifth, the yarde cut away, and Dissected overthwart.

The sixth, the Canell or pipe of the yarde divided at the entrance into the bladder.

The seauenth, the fore-part of the bladder and the yarde, together with the umbilicall vessels.

bb 5. The Artery distributed through the body of the yarde.

TABVLA XXIII.

of the Vreters, there is set on either side a smal Membrane or valve, after the maner of the leather latches of Bellowes; but this is an improper acception of a Valve.

The outlet of the bladder.

The third passage or the outlet of the bladder, yeeldeth way vnto the vrine, and is in the necke which is long enough, but straight, conueyed vnder the Share bones, and placed vnder the substances or bodies of the Yarde, and therefore a little crooked, and is carried

ed vpward from the Fundament vnto the beginning of the virile Member, to make his pipe or hollow Canell, and common passage.

In women this outlet is shorter [Table 23, fig. 8. about N] and broader [Table 27. 1] carried right downward, and is inserted into the necke of the Matrixe at the vtter and vpper end. Through this passage women auoide their vrine; men both their vrine and their feede, therefore men haue behind it [Tab. 22. Fig. 2, nm, table 23, Fig: 3, 7, R] two Glandules placed, called by *Galen prostate*, thicke and white, receyuing the insertion of the Vessels, which leade the feede called *vasa deferentia*. Gal. 16. v. 11
part. Cap. 9.

The necke of the bladder is most what fleshy wouen with many Fibres, some right vnder which lye hid transuerse also, which are placed at the beginning of this necke about the faide Glandules, and do contract it so, that the Vrine cannot drop out against our willes in any compression of the *Abdomen*, and strong retention of the breath; wherefore from the vse it is called the *Sphincter Muscle*, and from the Figure of the Greeke Letter *sigma*. *figmoides*. These Fibres being loosened not without a voluntary and strong compression of the Muscles of the *Abdomen* and *Diaphragma*, the vrine eyther by his quantity or quality and acrimony prouoking the bladder, is with contention or strife puffed forth: for if the vrine runne against our will, and without feeling, it is because the Muscle is either paralyticall, or too much cooled. But if this compression of the vpper parts againe do cease, the Fibres are contracted, and so the drops or remainders that continue yet in the passage are expelled. The necke of
the bladder.

The Sphincter
of the blad-
der.

If any man would see this transuerse Muscle lying betweene the right Fibres of the vtter coate and adioyned to the body of the glandules, hee must boyle the bladder lightly, or as we say parboyle it.

Furthermore below the glandules there are to be seen certaine transuerse fibres encompassing [Table 22. Figure 20, Tab. 23. Figure 3, 7, 8, 9. N] the canale or passage which Anatomists haue hitherto shewed for the sphincter. But if these were so, then seede coulde neuer passe without the vrine, as it hapneth in the *Gonorrhoea* or running of the Reines: for in the accompanying of a man with a woman, the muscle in this part must needs bee dilated, which being so, the vrine together with the seede must needs fall away, as it commeth to passe in them that want the vpper sphincter or the vse of it.

His vessels are veines, arteries, and sinewes; the veines and arteries are on both hands at the sides of the necke that they might not be carried farre without a conuoy, and might bee also safely inserted; and are doubly diuided; one part of them is distributed into the whole bladder with many small threds. The other part which is the greater in man because of the yarde, and the lesser in women, is carried downward according to the descent of the necke. The veines serue for his nutrition, for it is not nourished with vrine, neither doth it as the Kidneyes receiue any portion of blood with the vrine, but onely the pure excrement, and therefore stands in need of proper veines for his nourishment. The arteries serue for the recreation and refreshment of the life and heate: both of them proceede from the doubly diuided *Hypogastricall* braunch [Table 8. u u] of the hollow veine and great Arterie: wherefore in the inflammation of the bladder the inner ankle veine is to be opened, but in women they arise from the vessels which come vnto the necke of the Matrix. The vessels of
the bladder.
Veines.

Arteries.

A good obser-
uation.

It hath notable Nerues from the branches of the sixt coniugation which reach to the rootes of the ribs and from the marrow of the holy-bone, that the sence of excretion might bee stirred vp at those thinges which molest it; whence also come those exceeding sharpe paines that a man suffers when it is vlcerated, or but raw. Nerues.

His vse is to receiue like a bottle not only the vrine, which is the excrement of the moist Aliment, by degrees strayned through the Kidneyes and brought downe by the vreters; but also all dry excrements of which the stone is ingendered; which excrements the bladder doth not draw downe, but they are partly put downe by the kidneyes, partly they fall with their owne waight and of their owne accord, whence some call it the vrinall of the body. It also by constriction of the passage keepeth the water till a fit time of excretion, which it doth by a faculty mixed, that is partly Naturall and partly Animall, but the retention belongeth more properly to the Animall faculty, and the expulsion or excretion to the Naturall. The vse of
the bladder.

CHAP. XVII.
Of the Fundament.3. muscles of
the Funda-
ment.
1. Sphincter.

NExt to the Bladder lyeth the Fundament called in Latin *Podex* and *anus*, in Greeke *πρωκτος και ἀρχή*. It is the end of the right gut [Tab. 6. Fig. 2, 3, a] and hath belonging to it three muscles.

The first is called the Sphincter [Table 24. Figure 1. E] a round muscle (whence it is called also the *Ring*) compassing about the end of the right gut to hinder the exiture of the excrements: for it shutteth the passage so close that not so much as any winde can get out. This affordeth a beginning [Tab. 23. Fig. 1. 2. M] to the muscles [Tab. 23. Fig. 1, H I] of the yarde. The other two muscles are called *Leuatores ani* [Table 6. Fig. 2, 3, b c. Tab. 24. fig. 1. BC]

The first Figure sheweth a part of the right gut, with his Muscles cut from the body, which part when we take away the guts, wee vse to leane.

TABVLA XXIII.

A. A part of the right gut,
about which a string is tyed.

B C. Two Muscles drawing
vp the fundament after
excretion.

D. A Musculous substance
which groweth to the
roote of the yarde, but in
women it ioineth to the
very lower part of their
lap.

E. The Sphincter or round
Muscle of the Fundament.

2, 3. *Leuatores*, the lifters of the fundament. They are inserted into the vtter coate of the gut, and into the vpper part of the spincter, [Tab. 24. Fig. 1. E] and grow also to the roote of the yarde and the necke of the wombe. [Tab. 24. Fig. 1. D] Their vse is after excretion to retract the Fundament, and if they be weakned, men are constrained to vse their fingers to doe that office; but because we shall speake more of these muscles in another place; this at this time shall bee sufficient.

CHAP. XVIII.

The muscles and Nerves situated in the cavitie of the lower Belly.

BEside the Muscles of the *Abdomen* mentioned and but mentioned in the ninth Chapter of the second Booke, and the muscles of the Fundament named in the former Chapter, there are also other muscles appearing in the lower belly when the parts aboue named are moued. And those are two paires lying vpon the spondels or rack-bones. The first is the sixt muscle moouing the thigh or the first of his *benders*; they are called in Greeke *ΐσας*, in Latine *Lumbales*. The second is the seauenth mouing the thigh or the second of his *benders*, and it is called *Iliacus internus* the inward flanke Muscle, of which wee shall heare more in the history of the muscles of the thigh.

There are also two sorts of nerues disperfed through the lower belly. Some proceeding from the fixt paire of the marrow of the braine, from which are distributed branches to all the entralles therein contained, of which wee haue spoken particularly in the particular history, yet their production and continuation shall be better insisted vpon afterward. Other sinews there are arising from the marrow of the back, as it is contained in the rack-bones of the Loynes and the holy-bone; Of the loynes sometimes foure sometimes five paire, of the holy-bone alwayes five paire, of which we shall entreate in their proper place.

CHAP. XIX.

The bones of the lower Belly.

THe Bones which together with the fleshy parts doe make the lower belly, although they compasse not the belly round about as the other two Regions are compassed, yet are there some of them on his backe part, some on his sides, and some before. On the backe part are the rack-bones of the Loynes, the holy-bone, and the Rump.

Of the loynes there are five rack-bones [tab. 25. fig. 1, 2. from b to c] which are knit together with Cartilages and thicke ligaments, and aboue are tyed with the spondels [tab. 25. fig. 2. a] of the Chest, below they rest vpon the Holy-bone. [table 25. figure 1, 2. c.] The first of these Loyne racks is called *uerrigins* from the Kidneyes, which leane vpon it, the last some haue called *ασφαλινς*, that is, the Vnder-propper.

Finally the bones in the fore-part of the lower belly are called ossa pubis, [tab. 25. fig. 1, 2. pp. Tab. 26. fig. 13, 14. that which is below R and p] the share bones; they are tyed together in the middest of the share with a Cartilage [tab. 26. fig. 15.] they are very thunne, and haue the greatest perforation of the whole body. [Ta. 25. fig. 1, 2. qq. Tab. 26. fig. 12, 13, 14. q] These bones, together with the Holy bone, make that pelvis or Dish which containeth part of the guts, the bladder & the womb, marked in the 25. Table and in the first figure.

Of all which, we haue heere given you but a view, referuig the fuller Discourse vnto our Booke of Bones.

CHAP. XX.

Of the Breasts or Paps.

The reason why the Discourse of the breasts is here placed.

Their Names.

What creatures haue breasts.

The situation.

AL though the breasts or paps are not contained in the lower venter or compas of the Abdomen, yet as before the Gullet, so now these, because they bee parts which serue chiefly for nourishment, we haue thought this place fittest for their history. But because there is nothing so much vse of them in men as in women, therefore wee will first intreat of the breasts or paps of women, and then of men.

The Breasts therefore are called in Latine *Mamma*, in Greeke by Hippocrates *μαστος*, by Aristotle *μαστος* of *μαστω*, which signifieth to seeke, because in them Infants seeke their nourishment euen by a naturall instinct: Galen calls them *τις*. No creatures haue paps but such as can beget a perfect creature. And amongst those that haue them, none haue them set afore in the middest of their Chest but onely a man, & indeede this place is most fit for them. For being made for the milke sake which they containe, it behooued they should bee seated in that place where soonest and with most ease, because of the neighbourhoode of the heart which is the shop of heat, the blood might be altered & laboured thereinto; & where also the greatest quantity of the benigne & pleasant superfluity of the nourishment may be gathered.

Moreover, this situation serueth also for more conuenient suckling. For because the infant cannot go, it is necessary that it should bee embraced in the handes and armes of the Nurse; being so embraced it can apply it selfe to no place so fitly as to this; & out of doubt our wise Creator by this position of the breasts did set a marke of distinction between man and

and beast, for beasts do onely nourish their young, and afterwards neglect them: but men doe transfuse out of their heart into their young ones *την καρδιαν*, that is, a naturall affection, which the Latines hauing not beene able shortly to expresse, haue called *Pious loue*, or *piety*. For the Mother doth not onely nourish her Infants, but embraceth them and kisseth them; and so loue being neuer forgotten, at length growes reciprocall and mutuall. But least the heauy breasts should flage downe too lowe because a woman goes alwaies vp-right, they are knit and tyed by their whole *basis* or bottome to the bony part of the chest. They are two, (euen as the whole body almost is diuided into two partes) that like good handmaides they might serue their dame the wombe, which it selfe is as it were parted into two (for the Milke doth not come vnto the breasts til the infant be thoroughly perfected.) And that if there be two Infants, yet they may both at once haue wherewith to satisfy and nourish them, and therefore those creatures which accustomably bring forth more young, haue also more dugges to suckle them with. But if there had beene but one fastened to the middle of the Chest, neyther would the blood haue gotten so well to it, because it should haue had one continued bone vnder it which we call the breast-bone; and beside the infant could not haue bin so handsonly applyed vnto it:

The piety of parents.

Why two.

Why not one.

Their Figure.

Their forme is halfe round, they are hardish and seuered asunder by a middle distance, & in virgins before they be fit to conceiue they are imperfect, so that scarce anything appeares of them but Nipples; but as they grow fitter and fitter for conception, they begin to strut out, become hard and like pleasant Apples, whereupon *Aristophanes* calles them *μῆλα*. They represent as it were a halfe bowle, and when they arise two fingers high, then commonly the monthly courses begin to flow. In women that haue neuer conceived, they remaine knit and as it were gathered vp, but they grow as the belly and the infant in those that be with child. When the Infant is perfect and that the time of deliuerance draweth neere, they swell proportionably as much as the wombe: for there is great consent betweene them by the mediation of vessels, as we shall heare afterward. This consent appeareth, when the infant in the wombe either is not well, (for if it be weake the breasts are full of milke before their time, sayth *Hippocrates*) or is like to abort. Neyerther is it maruell, seeing their offices haue so great affinity, for the wombe was made to receiue the seede, and to perfect the creature, and the breasts to nourish it being brought into the worlde. Also when the infant begins to moue, then beginne they to rise and the nipples to strut: and moreover the infant is lodged on that side where the breast growes greater, whether it be the right or the left.

Their magnitude.

How the Breasts shew the weaknesse of the Infant.

In fat folke they are greater, and in some because of their great weight they hang lowe downe, as it is common among the women of *Ireland*, who neuer vse to tie vp their breasts. In some they grow euen to a monstrous greatnesse as long as they giue sucke, and fall afterward. In olde women they be long and flaccid or loose, so that in extreame age the Kernels and the fat being consumed, onely the skin and the nipples do remaine; sometimes, in such people they are knit wrinklingly vpward.

Irish women haue long and flaccid Breasts.

The parts of the breasts are externall or internall: without, they are cloathed with the Slogh or Cuticle and the true skin, in the middle is the nipple, of which afterward: the internal, are the fleshy Membrane or panicle, the vessels, the kernelly substance and the Fat. The membrane inuesteth their glandulous substance and their fat and knitteth them vnto the Muscles vnderneath by certaine Fibres sent thorough their substance, betweene which Membrane and the skin are the vessels, the Glandules or Kernels and the fat dispersed.

The parts of the Breasts.

Their Vessels are two sorts of veines [Table 27, ab] The first are *cutaneous*, proceeding from the branch of the Axillarie & Humerarie veins which often look very blew, especially in women with child and in nurses, and are distributed into the skinne of the Chest and into the breasts. Their inward veines are about the rootes, which doe not arise from the trunk of the hollow vein at the *Diaphragma*, but when the hollow vein hath first attained to the heart and thence to the collar or patell bones, it lendeth two branches accompanied with two Arteries downward through the whole Chest, and two veines from them are inserted into the Paps, which therefore go so long a iourney that in them the blood might be perfectly boyled; for as it goeth upward it passeth by the heart, and againe descending it is mooued and wrought by the motion of the *Thorax* or Chest which helpeth his more perfect concoction; and these are called the *Mammarie* or Pap-veines and Arteries.

Their vessels. Their outward Veines.

Their inward Veines.

The *Mammarie* descending veine commonly ariseth one on each side from the trunk of the veine called *sub-clauia*, that is, the veine vnder the collar-bones which are called *clauia*.

The mammarie Veines.

The Anastomosis of the mammary veins with the Epigastrick

The consent betweene the wombe and the breasts.

The milk cometh from the wombe to the breasts. How it is that the breasts draw more blood then is needfull for their owne nourishment. Why a milke nurse hath not her courses.

The mammary arteries.

The nerves of the breasts.

The Glandules of the breasts.

The final outlets of the breasts.

nes or clauiculae, and is carried vnder the breast-bone close by the gristles of the ribs, & getting out of the Chest, is vnder the right muscles of the *Abdomen* about the nauell inoculated by *Anastomosis* with the *Epigastricke* veine (which ariseth from the same branch with those which are propagated to the matrix and the necke thereof) which creepeth vppward vnder the right muscles with certaine small tendrils. From the *Mammari* veine betwixt the fourth and the fift ribbes, sometimes higher sometimes lower, there are sent certaine outward boughes through the middle spaces of the Cartilages which ioine the ribs to the breast bone; in men for the nourishing of the interior muscles; but in women (in whome sometimes they perforate the very breast-bone it selfe) both for the nourishment of those muscles, as also to carry the matter of the Milke to the glandules of the breasts in those that giue sucke and to nourish the breastes; for through them a great number of webs of veines are deriued, which nature hath endowed with the faculty of Milke-making. By these vessels sayeth *Baubine* (although others are of other minds) is made the consent betweene the wombe and the breasts (which is so great that onely contraction of them will prouoke lust) which are by them ioined as it were together, so that when the Infant groweth in the wombe, certaine common veines arising from them both doe afford it nourishment; and when the Infant is borne, that attraction of blood ceasing which was strong whilst the Infant remayned in the womb, all the ouerplus of blood floweth towards the breasts, and the breasts like cupping glasses doe draw and pul it blackward and from below. For *Hippocrates* sayth, The Milk cometh from the wombe to the breasts, which after the birth is to be the nourishment of the Infant; and when the woman hath brought forth, the beginning of the motion being once made, that is, if she haue once giuen sucke, the Milk is carried with full streame to the breasts. And this it doth not onely voluntarily, but the Paps draw more blood then their nourishment requireth: which traction or drawing is caused by the Infants sucking, by the amplitude of the vessels, by the motion of the Paps, and for the auoyding of vacuity or emptinesse: for the veines being exhausted by sucking, doe draw blood into themselves on euery side.

Hence it is that a woman cannot well at the same time haue her courses and giue sucke, and *Hippocrates* sayth that milk is German Cousen to the menstruous blood. But to speak as the thing is; the blood is not carried to the Pappes so much by reason of this consent of vessels, as because when the motion of the blood from the whole body to the wombe ceaseth, then the whole body exonerateth or emptieth it selfe into the glandules of the breastes. Wherefore their substance like that of a sponge is very rare or porous, that they might bee able to receiue the greater quantity of liquor.

There are also internall *Mammari* Arteries from the vpper trunke of the great Artery, which doe accompany the veines and are ioined with some branches of the ascendent *Epigastricks*. It hath nerves from the sinewes of the Chest which are carried through the skinne partly to the nipples; but the thicker nerue is that which cometh to the nipple from the first nerue of the Chest, and doeth communicate thereto exquisite sence, and is the cause of the pleasure conceiued by their contraction.

The Glandules or Kernels (which they cal in Latin *mamilla* or *mamma*, or rather glandulous bodies) which make the body [Table 27, 28,] or bulke of the Pap, are the greatest of the whole body; white, and do not as in most of the other creatures make one body, but are many and distinct, spongiuous and rare or porous that they might better drawe the Aliment vnto them and conuert it into milke; of these one is the greatest, placed vnder the nipple, and about it are set all the other small ones which cleaue to the muscles of the Throax or Chest.

Among these are infinite vessels with many windings and turnings wouen together, that the blood before in the veines and arteries perfected & receiued by the breasts, might in these boughs and turnings through the glandulous bodies, bee conuerted into milke, which is a surpluse of profitable Aliment.

These Glandules in Viginis are hard, in women with Child especially such as haue giuen suck when they are ful of milke they strut more, afterward they grow flaccid & loose, and are as it were consumed. About these is a certaine fat disposed, that it might cherish the heate of the vessels and glandules, and also make the breasts equall. But that the milke that is ingendered in the breasts might better passe out, the breastes are foreward acuminate or sharpned, and that it might not runne at wast but the Infant get it out by sucking, they haue exceeding narrow and straight outlets which are perceiued when the breast head

Table 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

is pressed that the woman that giueth sucke out of it, then and teates of the breasts, and about them, and teate should euery a more vnequall then a pimple, whele, or yard, whence it is more flaccid or looser and vnequall, very longer and blower. About this teate name it hath, vnequall men with childe and vnequall. From the disease crates saith, a man in his ring which was nipples and the ring gasses drawing heat take them, which is the proper vse of theirs owne childe, is

Table 27. sheweth the breast of a woman, with the skin flayed off. For the rest of the Table belongeth to another place.

- aa The Veines of the Pappes comming from those Veynes which are brought from the top of the shoulder to the skinne.
- β The Veynes of the Pappes comming from those veynes which thorough the arme-hole passe into the hand.
- γ The body of the Pap.
- δ The Glandules or Kernelles of the Pappes, together with the fat amongst them.
- ε The Mammary vesselles descending from the Patell bones vnder the brest-bone.

is pressed that the milke spinneth out, but especially when the Nipples are vlceraed in a woman that giueth sucke. And because the childe cannot take holde of the Pap it selfe to sucke out of it, therefore Nature hath provided the nipples to stand out, as it were the heads and teates of the breastes, which the Infant may enclose with his lips, and lap his tongue about them, and so draw the milke through the outlet or passage. But least this nipple or teate should euer and anon slip out of the childs mouth, it is made rough and rugous, and more vnequall then the rest of the skin.

The Nipples.

Why rugged.

Plato calleth it *σάκος* of *σάκος* to bud forth, in Latine *Papilla*, because it is like *Papula*, that is, a pimple, welke, or wheale. It is of a fungous or Mozy substance, somewhat like that of the yard, whence it is that by touching or sucking it groweth stiffe, and after will againe grow more flaccid or loose. In virgins this teate standeth not much out from the brest, and is red and vnequall, very like a strew-berry; in nurses, because of the childes sucking, it groweth longer and blewer: in old folkes it is long and blackish.

About this teate is a circle, called in Latine *Areola*, in Greeke *ὄρεα*, we know no English name it hath, vnlesse we call it the ring of the pap, but in virgins it is pale or whitish, in women with childe and nurses it is dusky, in olde women blacke, and the skin more rugous and vnequall.

The circle of the Teate.

From the disease of the wombe it is also sometimes yellow, somtimes blacke. For *Hippocrates* saith, a man may iudge of the wombe by the colour of the nipples, for if the nipple or his ring which was wont to be red grow pale, then is the womb affected. The colour of the nipples and the ring about them is also often made dusky and blacke by setting drawing glasses, drawing heades or such like vpon them to make them stand out that the Infant may take them, which may notwithstanding be preuented if care be had.

A good note for women.

The euil cuent of drawing glasses to the Nipples.

The proper vse of the breast, is to be a Magazine or Store-house of meate for the Mothers owne childe, or, that in them so long milke should be generated, as the Infant for his

The vse of the breasts.

nourish-

nourishment should stand in neede of it. For whereas it was accustomed in the womb to be nourished by the Mothers blood conueyed vnto it by the vmbilical veines, it could not so suddenly change that liquid for more solid nourishment, for it could not digest it, because when it is new borne, it is but tender and weake; beside sudden changes are very dangerous, wherefore it had neede of such a nourishment, as should not be too remote from the nature of blood: and that it might more easily be nourished, should also be liquid, sweete, and after a sort familiar vnto it; but such is milke which is made in the breasts. For so in growne men and women, the Aliments are in the stomach turned into Chylus, which is a Creame or substance like vnto Milke. Wherefore according to *Galen*, the first and chiefe vse of the breasts, is the generation of milke, that they may be ashamed, who for nicity and delicacie doe forfeite this principall vse of these excellent parts, & make them onely stales or bauds of lust.

A secondary vse of them, is in respect of their scituation, that they might be a kinde of couering and defence for the heart, and that themselves hauing receiued heate and cherishment from the heart, might again returne vnto it warmth, such as we get by garments we buckle about vs; especially this vse is manifest in women, in whom these breasts grow oftentimes into a great masse or waight, so as they being farre colder then men, their Entrals vnder the *Hypochondria* are warmed by them. It may also be added, that they are giuen for ornament of the Chest, and for a mans pleasure, as is partly touched before.

Note this.

Hippocrates in his booke *de Glandulis* addeth another vse of the Paps, that is, to receiue excrementious moysture: for if, sayeth *Hippocrates*, any disease or other euent, take away a womans Pappes, her voyce becommeth shriller, she proueth a great spitter, and is much troubled with payne in her head.

The Paps of Men.

And thus much of the Pappes of women. Now men likewise haue Paps by nature allowed them, scituated also in the middle of the breast, and lying vpon the first muscle of the arme called *Pectoralis*. They are two, a right and left, but they rise little aboue the skin (as they doe in women) because they haue scarcely any Glandules, for they were not ordained to conuert or containe milke. Yet we do not deny but in them is generated a humour like to milke, which *Aristotle* in the 12. book of his history of Creatures calls milke, but it will not at all nourish, albeit we haue seene it in some men something plentifull.

What humor is in them.

The comparison.

The Paps of Men are compounded of skin, fat, and nipples, which appeare yea sometimes hang forth in them because of the abundant fat which in corpulent bodies is more about that place then in any part of the Chest beside: the nipples of men are somewhat fungous and also perforated.

Their vse.

They haue Veines, Arteries, and Nerues, for their nourishment, life and sence. Their vse is to defend the heart as with a Target or Buckler; or it may bee sayed, that they are giuen for ornament, that the breast should not be without some representation in it. The Nipples are the Center in which the veines and nerues doe determine, which also are therein conioyned.

And here we wil put an end to the History of Parts belonging to Nutrition or Nourishment, and prosecute our intent to discusse the Controuersies and Questions which may arise concerning them.

A
Dilucidation or Exposition of the
Controuersies concerning the parts
belonging to Nutrition.

QUEST. I.

Whether the Gutes haue any common Attractive faculty.

THe Physitians of old time haue beene at great difference among themselves, whether the Guts haue only an expulsive faculty, or all those foure which serue as Hand-maides to nourishment, the Drawing, Reteining, Assimulating, & Expelling. The occasion of the strife was given by certaynes places of the Greekes and Arabians which were of doubtful construction, for sometimes they acknowledge those foure faculties, sometimes deny them. Our purpose is to skanne and fan this question as neere as we can, beginning our disputation at the Attractive or drawing faculty. But because we would not be puzzled in the equiuocall or want-way betwixt a Faculty and an Action: it shall not bee amisse to sticke downe some stakes, to lay some foundations for our better direction: such are these.

Of Actions some are Common or official, others Priuate or peculiar. The common actions were ordained either for the behoofe of the whole, or at least for more parts then one. So the liuer doeth sanguifie the aliment, not for his owne vse alone, but for the nourishment of the whole body. The heart and the braine doe ingender vitall and animall spirits, to giue life and sence to the whole man; not only for their own particular and priuate vse. The stomach chylieth the meate, not for it selfe (though it take some pleasure in it) but for the liuer. The spleene, the bladder of gal and the kidneies, do not draw the melancholy iuyce, the fiery choler, and the whaey vrine for their owne nourishment, but to depurate and cleanse the Liuer and masse of blood: wherefore these actions are called officiall, because they serue and minister vnto many.

Priuate Actions or peculiar, are such as serue only for the conseruation of priuate and peculiar parts. So the stomach beside his chylickation hath also a particular action whereby it intendeth his owne proper nourishment, drawing, reteining and concocting blood familiar vnto it selfe and expelling the reliques of the same. These things are so notoriously knowne to all men that they neede no curious demonstration.

Another foundation to be layde is this: that for peculiar and priuate Traction & expulsion, there is no neede of the helpe of fibres, but only for the common and officiall; because the priuate is accomplished alwayes without locall motion, but the common with it either alwayes or for the most part. Bones, gristles and ligaments, doe draw and expell without any contraction of fibres; for who euer obserued them to moue in their traction? But as the Load-stone although it moue not, by an inbred and occult propriety draweth yron; and plants which sticke immoueably in the earth, doe suck & draw out of the same earth a iuyce familiar vnto their nature: after the same manner the particular and singular parts of the body out of the masse of blood by a propriety of their own, doe draw and drink into themselves a proper and peculiar nourishment. But the common and officiall traction or expulsion, because they are almost alwayes made with locall motion doe therefore stand in neede of the helpe of fibres. So the motion of the hart although it be naturall, yet is not accomplished without the helpe of fibres, for in his *diastole* or distention, it draweth by right fibres blood through the hollow veine into the right ventricle and ayre by the veynal artery into the left; againe by the transuerse it expelleth spirits, blood and fumed vapors. In like manner the wombe by right fibres draweth the seed of man, and by transuerse is contracted for the exclusion or birth of the Infant.

Two kinds of
actions.
Common or
officiall.

Priuate or
particular.

There is no
need of fibres
to the perfor-
mance of pri-
uate actions.

primus.

Their reasons.

Answer to the
arguments.

These foundations being laide, the state of the question standeth thus. When it is demanded whether the guts haue any attractive faculty, we doe not enquire about the priuate & peculiar attraction of the guts, for that is beyond controuersy, considering that life is sustained by nutrition, which is alwaies accompanied by those foure in-bred faculties, attraction, retention, concoction, and expulsion; but the question is concerning a common or official Traction, that is, whether the guts haue power of drawing the Chylus from the stomacke. We thinke they haue not, and *Galen* fauoureth also our opinion; for in his books of the *use of Parts*, he sayeth, *The Guts stand not in neede of an attractive faculty*, and againe, *The Guts haueing no neede either to draw or to reteine because their motion is simple, haue also but simple Fibres*; and in another place euery Gut hath in each coate circular fibres, *For they are contracted only but draw nothing*; the same also he auereth in his 6. booke *de Locis affectis*.

But you will say, if the guts draw not the Chylus, what power or faculty is it which bringeth the same vnto them? Doth the stomack driue out of it selfe so profitable an Aliment? We answer, *Galen*s meaning is, that the Chylus is boyled in the stomack, & that the *Pylorus* or lower mouth all the time of concoction is closely shut vp, that nothing either thicke or thinne may be able to passe away before it be concocted, leuigated and perfectly laboured. When this concoction is throughly celebrated, then is the stomack delighted with the chylus, imbraceth it a while, as being now become familiar vnto it; afterward Nature in a wonderfull prouidence openeth a certaine small membrane, and then the Chylus as it were an ouerplus or superfluity, is driuen forth and falleth into the guts; in whose boughts & circles while it maketh stay, the thinner part like vnto creame is sucked away by the veines of the mesentery; but the thicker by his waight falleth vnto the great guts, and by the circular fibres is thrust forth. Such is *Galen*s true and sound Philosophy concerning this question whereby we are taught that the Chylus is not *drawne* by the guts, but *driuen* into them by the stomacke.

Notwithstanding there want not many among the late writers, who perswade themselves that the guts, especially the smal ones, haue this common tractive faculty inherent in them, and I am perswaded that they build their opinion vpon the authority and som light reasons of the Arabians. *Anicen* writeth that the Chylus falleth from the stomack into the guts, by the helpe and assistance of two faculties; one expulsive of the stomack, & another attractive of the guts; and this also he repeateth in his thirteenth booke *de Animalibus*.

To this authority they adde a threefold reason: First, no man will deny but all the parts do draw a familiar iuyce vnto themselves. Now the Chylus, say they, is the familiar Aliment of the guts, by which they are nourished as the stomack is. Again, if the Chylus be onely driuen out or excluded by the stomacke, then is that motion violent; but it is absurd that nourishment should be made by force or violence, for then it would not endure; the nourishment therefore is drawn not driuen. Lastly, the guts haue right fibres extended in their length and those wee know are onely prepared by Nature where traction is necessarie as being their proper worke.

But those arguments are so sleight & triuiall as a nouice may see their weaknes as he runs. For, first we may not admit of that *paradox* which they obtrude concerning the nourishment of the guts and the stomack; for indeede the stomack is not nourished by the Chylus, but onely delighted with his presence, otherwise, for his nourishment, it draweth bloud by the *Gastricke* and *Coronary* veine, which also it assimilateth as in due place we shall proue. And the guts neither are they nourished by the chylus, but by bloud which is brought vnto them by the meseraick veines; the guttes therefore draw not the Chylus for their nourishment. Whereas they say that the motion of the stomack driuing out the Chylus is violent, I thinke they are farre out of the way; it is rather naturall because it followeth his contraction; against which the natural form of the Aliment, that is, his gravity or waight doth not repugne.

Lastly, we altogether deny that which they affirme concerning right fibres, for in either coate of the guts there is only one kinde of fibres and those circular; & if any right Fibres do appeare, yet is it not in the smal guts which containe the Chylus, but only in the last which is called the *right gut*, in which the excrements are reserued for immediate euacuation.

But let vs grant, that in both the coates of the guts there are right Fibres, yet it followeth not that there is any such drawing faculty as they dreame of, for right Fibres are not alwaies ordained for traction. And this *Galen* doth excellently declare in his fourth booke of the *use of parts*, where he saith, *That the right gut only hath right Fibres allowed it not for traction, but for preservation of the transverse*. For it was to be feared, least the circular Fibres should sepa-

rate

rate or drawne asunder, vnlesse on the outside they had been strengthened by right, as it were by bands or ties; so the Coates of the Veines haue right Fibres not for attraction, but onely *propter duritiem*, as wee say, that is, to hinder an inconuenience. So Chyrurgions for the better reteyning in their due place circular bands, do strengthen them with right Ties or Deligations. And thus much shall be sufficient to haue saide concerning the Attraction of the guts.

QUEST. II.

whether the Guts haue any common Retentive Facultie.

THE authorities of *Galen* aboue alledged do prooue but one facultie of the guts, to wit, the Expulsive; yet there are some which striue out of *Galen* himselfe to prooue common and officiall-Retentive and Concocting Faculties also. Concerning the Retentive we will first see and then of the other. *Galen* discoursing about the nature and causes of the *Lienterie* (a disease wherein the meate is auoyded whole and vndigested as it was eaten, without any notable alteration) referres it to the weakenesse of the retentive vertue; not of the proper Aliment that is of bloud, but of the Chylus containd; the same also doth *Auicenna* determine. Moreover *Galen* 3. de *symptom. causis* sayeth that the concoctiue facultie in Children is stronger, but the retentive and expulsive weaker, because they haue tender bellies, or doe oftentimes vnburden nature; now those things that are auoyded are containd in the guts, the retentive facultie therefore of the guttes is the weaker.

Againe in his booke of *experienced medicines* he prescribeth stipticke or binding medicaments for the fluxe of the belly, to roborate or strengthen the vertue of the guttes; and wee in the *diarrhea* doe apply outward strengthening and astringent things. Adde hereto that most men are somewhat bound rather then soluble, the cause of which action they referre vnto the strength of the retentive vertue, out of *Galen*s commentarie vpon the xx. *Aphorisme* of the second section. Lastly the retention of the Chylus & of the excrement is necessary; of the Chylus, that the Aliments should not suddenly slip away & wee thereby become slaues to our insatiable throates and paunches; of the excrements, least we should be contrayned continually and vnseasonably to auoyde them.

These and such like things they propound, to teach that there is some force and power in the guttes to retaine the Chylus and the excrements, which because they seeme to bee very strange, and abhorring from the determinations of *Galen* and the ancient Physitians, it shall not be amisse to make interpretation of *Galen*s wordes. The *Lienterie* is a disease not of the guttes but of the stomacke, and it is a *symptome* in the ouer hasty egestion or expulsion of meates scarcely at all altered or changed; for *Galen* thus defineth the *Lienterie*, *when the meate is auoyded by the sledge not at all altered or concocted*; and therefore they doe ill that call it a *leuitie* or smoothnesse of the guttes because it may be sometime when they are rough, being an affection of the stomacke onely and not of the guts; for although they be smooth and slippery, yet if the stomacke doe sufficiently boyle the Aliment, we are neuer troubled with the *Lienterie*, because the nature of it consisteth in the priuation of the first concoction, which is celebrated in the stomacke, and in a heady or sodaine egestion; wherefore they conclude amisse that the *Lienterie* proceedeth from the weakenesse of the retentive facultie of the guttes, for that *Galen* conceiteth not; who discussing the causes thereof, referres them to the distemper of the stomacke dissoluing the strength of all his faculties and to a light and superficiall exulceration, whereby that cometh to passe in the stomacke prouoked by the *Lienterie*, which hapneth in the bladder through the strangurie. It is true that the distemper of the guts doth also breed a *Lienterie*, but not at the first had, vnlesse the stomacke also doe sympathize with them, or be drawne into consent by reason of their mutuall society, communion and neighborhood.

And whereas *Galen* writeth that Children are oft troubled with vomitings and loosenesse, hee referres the cause thereof to the weakenesse of their retentive vertue; not of the guttes but of the stomacke, for their fibres are softer; beside their liquid eiections are caused by their continuall eating and greedy appetites, the strength of their naturall heat desiring more then it can containe or concoct; whence it cometh to passe that the fibres, as it were

cines in fluxes.

Galen.
The true cau-
ses of costive-
nes.

The reason of
the conuoluti-
ons of the guts

The conclusi-
on.

Those things which they obiekt concerning stipticke medicines which corroborate the guts, and stay the fluxe of the Belly, are but of small moment; for we doe not therefore apply them to strengthen the Retention of the guts which is none at all, but to bind or Contract the veines of the mesenterie, which are dispersed in infinite braunches through the coates of the guttes, and doe empty into them malignant and superfluous humors; or else to thicken, refrigerate, or appease those raging humors which in substance are very thinne, in their Temper very hot, and in their quality very sharpe and coroding; that so they might become more vnapt to moue with such violence and force as they are wont. And what I pray you is more absurde, then to referre the cause of the striction of the belly to the strength of the Reteining vertue? Let them rather harken to *Galen*, who in the third booke of the causes of *Symptomes*, elegantly assigneth the causes of slowe deiection, sometime to the weaknesse of the expulsive power, sometime to the dull sence of the guttes, sometime to the thicknesse, stipticke, or binding nature and small quantitie of that which is eaten; sometime to the weaknesse of the muscles of the *Abdomen*, who haue a great hand & beare a great part in the auoyding of the excrements; but concerning the Retentive power of the guts he addeth not a word, neither maketh mention thereof.

Lastly, whereas they obtrude vnto vs, the necessity of their Retention of the Chylus and the excrements, we admit it very willingly; but doe not ascribe it to the retentive faculty of the guts: for toward the reteyning of the Chylus, the wisdome and prouidence of Nature hath provided the manifold boughts, doublings, and conuolutions or writhen complications of the guttes; so that in so long a iourney and intricate a passage, it is not possible that almost any part of the Aliment should ariue at the port. Esquiline which before was not met withall by the sucking mouthes of the almost infinite veines of the mesenteric. And for the Retention of the excrements, it is not a naturall but an Animall action; because it is performed by the helpe of muscles, to wit, the sphincters, which doe constringe or gather together the lower part of the right gut, that the excrement might not bee auoyded without the commandement of reason and consent of the will. It is therefore hence manifest that the guts haue no Naturall power to reteine the Chylus or the excrement.

QUEST. III.

Whether the Guttes haue any Concocting Facultie.

Three things
required in all
concoctions.

That in euery Concoction there are three things necessarily required; a Preparation, the Concoction or boyling it selfe, and a Perfection after it, *Galen* is a plentifull witnesse. So the preparation of the first Concoction is in the mouth, the Cotion it selfe in the bottome of the stomacke, and the absolution or perfection in the small guts: the preparation to the second Concoction is made in the veines of the mesenteric, the Cotion it selfe in the *Parenchyma* of the Liuer, and the absolution or perfection in the great vessels. In like manner the seede attaineth a kind of rudiment in the *Preparing vessels*, but his *Idea* or forme in the testicles and his perfection in the *Parastata*. The Animall spirite hath a delineation in the wondrous nettes or webbes of Arteries, his forme in the middle ventricle, his absolution in the latter ventricle of the braine; so that in the workes of Nature these manifold degrees of operations doe euery where appeare.

This Concoction of spirites or of Aliment whether it bee priuate or officiall is performed without the helpe of fibres, onely by the assistance and inbred proprietie of our naturall heate, and therefore by *Galen* it is called *Alteration*, and by him not denyed vnto the guts, for so he writeth in his fourth booke of the vse of partes: *The guttes though they were not ordained to Concoct the Chylus, but onely to containe and distribute it, yet because Nature is neuer idle, it attaineth in the passage through them, a more perfect elaboration, even as in the greater vessels there is a certaine facultie of perfecting the blood which was before made in the Liuer.* And this opinion of *Galens* doeth *Arctens* and *Auerroes* follow, which also is seconded by good reason: for the substance of the guts and the stomacke is all one, whether you regarde the Temper or the Color or the frame and texture of their coates. Wherefore

Galen 4. de usu part. lib. 3. de nat. facult. cap. 1. de causis & signis Chronic. morb. cap. 15.

fore the Chylus is concocted in the stomacke, and there attaineth the *species* and forme of Chylus, but as it stayeth in the conuolutions of the guts, and the rugged foldes of their inmost coate, it acquireth also a further alteration.

I am not ignorant, that there is a new Paradoxe maintained by some, to wit, that the guts haue more power to concoct the Chylus then the stomacke, and that in the time of concoction, the *pylorus* is not shut, but that the aliment not yet throughly boyled, falleth thorough the stomack into the guts; and they instance in wounds of the *Hypochondria* and small guts, whence (say they) doth issue a Chylus not yet perfectly concocted, and therefore it hath not his forme or perfection in the stomack.

A paradoxe.

Furthermore, in *Exomphalos* or the rupture of the nauell, the meate passeth forth not perfectly laboured; & in the heighth of Summer when we drinke small drink, we doe instantly feeble the cold in our guts. We answer, that they do not perceiue that in the cases instanced, the guts are ill affected, and the stomack out of hand drawne into consent with them, as well because of their communion and similitude of substance, as also because of their vicinitie: for *Hippocrates* in his Booke of humors hath this golden saying, *These partes which are neere Neighbours, or haue community of substance, are at the first hand and very notably affected.*

Obiection.
Exomphalos,
Answer.

Hippocrates.

It is therefore no wonder that crude or inconcocted and liquid Aliment should flowe from a wounded gut. I confesse that liquid things do sodainely fall downeward, so also is their alteration sodaine and quicke. But they can hardly be perswaded, that the great abundance of meate deuoured by Rauen-stomackes and Trencher-friends can be conteyned in the stomacke alone, seeing *Hippocrates* saith, that the amplitude thereof exceedeth not five handfuls. Yet they must know, that the substance of it is Membranous, and is easily distended into all dimensions: beside, these great gourmandizers do not perfectly concoct the Chylus, because the portall Membrane is loosed before due time by the weight of so great a quantity. We conclude therefore, that the Chylus is concocted in the stomacke and perfected in the smaller guts.

Obiection.

Hippocrates.

Answer.

QUEST. IV.

Of the Expulsive vertue of the guts, and their Peristaltick motion.

That all the guts haue their expulsive faculty very strong, not only for the auoiding of their proper, but also of common excrements; is so manifest, that it needeth no demonstration; as that wherein we are conuincd by the authority of learned men, by the structure and frame of the guts themselves, and by the necessity of this kinde of action. To repeate *Galen*s words out of his sixth Book of the vse of parts in many places, out of his Books *de locis affectis* & *Naturalibus Facultibus*, were to abuse my owne time and your patience. In the structure of the guts if it be well considered, wee shall finde both coates wouen onely with circular and ouerthwart Fibres, ordained for expulsion.

Authorities.
Galen.

And if these things will not moue the froward minds and headstrong wits of men, yet the necessity of the action, which is the snall cause (and cheefe in Nature) must necessarily conuince them. For the excrements being of necessity to be auoyded, the Facultie by which they are auoyded, must needs also bee necessarie; yea more necessarie then the attractive, Nature being ever more diligent to expell that which is noxious or hurtfull, then to attract that which is profitable or behoouefull; and that is the reason why in men that lye a dying, the expiration is stronger then the inspiration, because in expiration the fumed or smoaky vapour which is offensive to the heart, is thrust out; in inspiration ayre is drawne in, which is naturall and familiar vnto it. The expulsive vertue therefore of the guts, is stronger then the rest.

Arguments

The necessity
of the expul-
sive faculty.

Why in the
instat of death
the expiration
is greater then
the inspiratio.

But all this while the manner of this expulsion is not manifested, which in the next place we will endeauour to make plaine vnto you. The excrements are expelled by locall motion; and this motion is double, one Naturall another Animall. The Naturall is proper vnto the guts, the Animall to the Muscles of the *Abdomen*. I call that Naturall which is not voluntary, and that Animall which is done with choyse and discretion. The Naturall motion, which the Ancients called *peristaltic* is accomplished by transuerse and orbicular Fibres contracting the Guts. And this naturall motion is againe double, One According to Nature, another Against Nature. The first is accomplished when the Guts doe contract and gather them-

The motion
of the Gutes
double.
Naturall mo-
tion double.

themselves from above downward, in which motion offensive humors, winde and excrements are driuen down; the other quite contrary when the circular Fibres do gather themselves from below vpward, which is called *ἀνακίνησις*: and in this motion the wind, the Chylus, & the excrements are auoyded by the vpper parts, nothing by the lower although such euacuations be prouoked by sharpe Clisters. *Galen* saith, *This motion hindreth the wind from coming downward, yea it maketh it flye vpward.*

Galen;

Hippocrates.

The causes of the depraued motion.

The manner.

Hippocrates acknowledgeth a threefold cause of this depraued motion, *Inflammation, a confirmed oppilation or stopping, and sometimes a light exulceration.* Inflammations streighten the passages, oppilation altogether shutteth them. So then the excrements hauing no current passage, the expelling faculty following first of all the order instituted by nature, beginneth her contraction in the vpper part, to expell the excrement downward; and this it endeoureth againe and againe, but being frustrated because of the streightnes or stoppage which opposeth her, she inuerteth the order, and begins her contraction from below, and that with such violence, that (alas the while) the Chylus and the excrements are thrown out by the mouth: so diligent and circumspect is Nature to vnburden it selfe of that which is noysome or offensive.

Againe, a light exulceration may cause this depraued motion; as, when the gut is afflicted by the pruritatio or goading of the vlcer it transmiteth vpward such things as would offend it, & as it were altering her saile, beares her course vpward against nature, which before she held downward. This *Peristaltick* motion which is contrary to the naturall, those haue miserable experience of which are afflicted with the lamentable and odious disease called *Ileos* or *Miserere mei Deus*, wherein the seate or fundament is so closed, that a Needle cannot be thrust into it, & if any Clisters be with much ado administred, they are incontinently sucked vp, the circular Fibres contracting themselves from below vpwards. This disease *Hippocrates* in his book *περί τῆς πάθης* calleth a head-strong, sharpe and dangerous affect.

The Ileos.

Hippocrates.

The naturall motions of the guts.

The manner of it.

The vse of the midriffe in the auoyding of excrements.

There is another motion whereby the excrements are auoided, which is *Animal and voluntary*, wrought and accomplished by the help of the Muscles of the *abdomen*; which being contracted do presse and straine the guts and so shut out the excrements, which motion is also furthered by the Midriffe and the Rim of the belly. For the eight Muscles of the *Abdomen*, compressing equally the paunch and the guts, doe alike and indifferently drive the excrements both waies, as well toward the stomach as toward the seate; it was needfull therefore that there should be some assistant part which should drive it downward and turne it from above, which office the Midriffe performs.

QUEST. V.

Whether Clisters can passe upward vnto the Stomacke.

Ecause I haue somtimes heard Physitians disputing about the ascent of Clisters, and haue read *Galen* and *Rhasis* their contrary determinations concerning this matter, I haue thought it fit a little to discusse the question in this place, the rather because the truth may be demonstrated by Anatomickall euidence. *Rhasis* is

Rhasis opinion

Continens is.

Galen opinion

of opinion, that Clisters may ascend vnto the stomach, and are often cast out by the Nostrils, his words are these. *If a Clister bee with great force and violence shot vp, it wil arise at the Stomack: if it be put vp gently and by degrees, it scarce reacheth aboue the great guts.* *Galen* on the contrary iudgeth, that though the Liquor be neuer so forcibly driuen vpward, yet it will scarce reach vnto the empty gut. For in the first book of his Method, he cureth Vlcers of the Lungs, Chest and Stomack by Medicines taken at the mouth; but the vlcer of the guts, both by things taken at the mouth, and also iniected at the fundament with this difference, that if the vlcer be in the great guts he vseth rather Clisters; if in the small, then he sticketh more to medicines at the mouth. The like he repeateth againe in the 13. of his Method, and to him we rather listen in this case then to *Rhasis*; for I haue obserued that the guts are seue times as long as the body of the man whose guts they are; and *Hippocrates* measureth them to be thirteene cubites; and yet that is not all, for the manifold girations or conuolutions whereinto they are circled do breake the force of any iniected liquor.

The great length of the guts.

I thinke therefore that such Liquors do nor reach aboue the blinde gut. For prooffe heereof saith *Laurentius*, I will tell you that which haply few hitherto haue obserued. Let the

the guts be dried and blowne vp a little, & poure some water into the gut called *duodenum*, and it will presently issue out at the right gut; but on the contrary if it be powred into the right gut it wil stay in the appendix of the blind gut because it can get no farther; which proueth that in the end of the blinde gut there is valve which Nature in great wisdom hath set to hinder the refluence or returne of the excrements and vnprofitable humors, such an one as appeareth in the passage of the Choler into the Guts & in the vessels of the heart.

Laurentius his instance that Clifters cannot passe vp to the stomach. The valves of the guts.

But it will be objected that *Galen* in his third booke of the Causes of Symptoms sayeth, That some haue had Clifters so giuen them, as they haue beene cast vp by the mouth, even as the faeces or excrements in that miserable disease called *Ileos* or *volvulus*. We answer that *Galen* here doth not contradict himselfe: for it is one thing to speake of the stomach when it is well affected, and another when it is ill affected. For if the stomacke be well affected the liquor can neuer arise vnto it, but if it be ill affected or affamished, as in the disease called *Boulimos*, it draweth from below not onely such humours as are iniected by the fundament but also the excrements themselves. For as the pined or greedy Liuer draweth from the veines crude & vnconcocted iuyces, so is it with the stomacke, yea with the mouth; for we see what raffe & what odious viands hunger maketh toothsome to such as are pinched therewith.

Objection.

Answer, and Galen expounded.

The force of hunger.

Againe, if the naturall motion of the guttes bee depraued, the circular fibres gathering themselves from below vpward may make a Clifter or other liquor ascend vnto the stomach. If it be objected that nourishing Clifters are carried vnto the liuer, I answer that they arise not thither either of their owne accorde, or by the violence of the liquor iniected, but they are drawne by the veines of the mesentery and thence transported into the Liuer.

Another cause that draweth liquor to the stomach.

How nourishing Clifters come to the Liuer.

QUEST. VI.

Of the Euill Saour of the Excrements.

Any men that are but sleightly seene into the course of Nature, doe wonder much why in a sound body and in a Temperate man the excrements of the Belly become so vnfaourie and abhominably sented, because all stench is the consequence of corruption: and corruption or putrifaction hath for her efficient cause outward and acquired not inbred heate;

Of the saour of excrements.

For whose better satisfaction we say that Physitians acknowledge a double cause of this fœtor or stench, an Efficient and a Materiall. Concerning the efficient they say, that our heate though it be one in regard of the subiect, yet in different considerations it is diuerse, and may be two wayes considered, either simply as it is heate, or else as it is inbred heate and the instrument of all the functions of the soule. As it is heate, it continually feedeth vpon and consumeth the moisture; as it is inbred it boyleth or concocteth, assimilateth and ingendreth; so from the same heate doe flow diuerse yea contrary motions.

A double cause of it. The efficient cause is heat.

Whilest the Chylus is made in the stomacke, the naturall or inbred heate insinuateth it selfe equally and alike into all the parts of the matter; gathereth together those thinges that are correspondent to our nature and separateth the rest: the first are drawne away into the Liuer by the veines of the mesentery, but the other which cannot bee assimilated are thrust downe into the great guttes; and there as vnprofitable are forsaken by the naturall heate; wherefore the heat worketh vpon it no more as it is inbred or direct from the soule, but simply as it is heate taking the nature of an outward heate, and thence comes the stench. Adde hereto the fitnessse of the matter: for these superfluities are crude and verie moyst whence comes putrifaction; but if the humour bee drawne away the putrifaction is lesse, and the saour not so noysome.

And this is the only reason why the excrements of a man most temperate, haue a worse saour then those of other creatures; because a man vseth very moyste nourishment and very diuerse, that is of seuerall kinds, and leadeth a life more sluggish and sedentarie: other Creatures feede vpon dryer Fother and so their excrements become dryer. And this cause *Aristotle* assigned in his *Problemes*: where asking the question why the excrements of the Belly the longer they are retained are lesse vnfaourie, and on the contrary the vrine the longer it is kept smelleth the stronger, he resolueth it thus: Because, sayeth hee, in the long stay, the excrements are dried, and so the nourishment of putrifaction is subtracted or drawne away, which is not so in the vrine.

Why the excrements of men are more stinking then those of other creatures. *Arist. Proble. sect. 13.* *Aprobleme.*

Now

Now the reason of the forme and figuration of the Excrements, is because of the Chambers and cels of the Collicke gut, wherein it swelleth into round and broken peeces.

QUEST. VII.

Of the substance and the scite of the guts.

Galen.
What the substance of the guts is.

Hippocrates.
Aphor. 20.
sect. 4.

Certaine places of *Galen* & *Hippocrates* reconciled.

The error of the Ancients about the scituation of the guts.

Galen.
Com. in 3. Epi.

Divers opinions.

Different conceits about the ascending of the Colon.

Why the pressing of the Spleene makes melancholy bodies to avoid wind downward.

BEfore wee passe from the guts, it will not bee amisse to reconcile some different places of *Galen* concerning their substance. In his Books of Method he saith, that if the guts be wounded or vlcated, they do very hardly ioine together againe, especially the smaller, because their substances is neruous & membranous: but in the 14. book of the vse of parts, he writeth, that the guts & the stomack because they are Instruments of concoction, have a fleshy Composition. And the same *Hippocrates* insinuateth in his *Aphorismes*, where he saith, That if upon a Dysentery or bloody Flux little Caruncles or ragges of flesh doe passe away by seidge, it is a mortall signe. The truth is, that the substance of the guts is neruous or sinnowy, but yet throughout also replenished with fleshy Fibres, so as it may bee saide to bee both Membranous, and also fleshy. Like as *Galen* calleth the wombe sometime a membranous, sometime a fleshy part.

Concerning the scite or position of the guts, the Ancients seeme to haue erred, because they thought that the great guts did occupy the lower part of the belly, and the smaller the vpper: but the truth is, that the Colon which is the greatest of all the rest, runnes vp vnto the hollownesse of the Liuer, and the bottome of the stomacke; but the Ileon is extended downward vnto the share-bones. I conceiue that the Dissection of Dogges and foure-footed Beasts deceiued them. *Galen* himselfe speaking to the capacity of the common people, calleth the great guts the lower, the small guts the vpper, yea and many Physitians at this day are mistaken, distinguishing the Dysentery of the smal guts from that of the crasse or thicke, by this, that if the paine be in the vpper parts then the disease is in the small; if in the lower, then in the great guts.

Concerning the scituation of the Collick gut, there are diuers opinions; some do therefore thinke it ascendeth vnto the bottome of the stomack, that by his contaction as also by that of the neighbor parts, the concoction of the stomacke might be furthered; others imagine, that it is therefore conueyed to the hollow of the Liuer, where the bladder of gall is seated, that the expulsive faculty of the Colon, which lyeth as it were a sleepe, might by the sweating issue of choler be better awaked and set on edge.

Another sort there are who imagine, that the Colon giueth way to the smaller guts, walling them about in manner of a ferce or rampert, comming not neere the center of the Mesentery, and that therefore it taketh vp the left side of the body, that the greater branch of the Port-veine called *Mesentericus*, might with a shorter cut be inserted into the guts and carry or transferre the Chylus vnto the Liuer by a neerer way.

Some there are, who thinke that the Colon adhereth or cleaueth to the bottome of the stomacke and hollow of the Liuer, that by their contaction the remainder of the Aliment which stayeth in the chambers of the Colon, might receiue more perfect concoction. Moreover, they giue this reason of his scituation aloft, that that part of the Chylus which is therein contained might not so soone passe away, and so there might be more perfect and accomplished exsuction of the creame, for which cause also the cels and chambred conuolutions of the Colon, as also the blinde gut were ordained.

This collick gut is indeede the largest or most ample of all the rest, but where it toucheth the Kidnies and the Spleene it becometh narrower, lest it should presse the spleene, whence it comes to passe, that those whose spleens do swel or be notably stuffed, can hardly auoide any winde downward, vnlesse the spleene be pressed.

And thus much concerning the difficulties or curious questions about the guts, wherein wee haue bene somewhat more prolix, that such as delight in the contemplatiue part of Anatomy might not go away from vs altogether vn-satisfied. The stomack followeth.

QUEST.

QVEST. VIII.

Whether the upper mouth of the stomach be the seate of Appetite.

Seeing the liue-tide of euery creature is inconstant, and like a poaste passeth swiftly away, because of the continuall effluxion or expence of the threefold substance wherein it consists, Nature being vigilant & carefull about her owne preservation, endeouoreth continually to make vp the breach by Respiration and Nourishment. By respiration the spirituous, by nourishment the fleshy & solide substance is restored. And hence it is that our nourishment is threefold, *Aer, meate, & drinke*. But because there can be no nourishment without Appetite, Nature hath dispensed to euery part a certaine desire, wherby as by goades they are pricked forward to draw and sucke into themselves conuenient and familiar Aliment. But this desire in the particuar parts of the body is without sense, for they feele not neither perceiue when they draw or sucke such conuenient aliment. Wherefore, lest the parts should pine away when they are exhausted & as it were hunger-starued, nature hath framed one part of exquisite and perfect sense, which alone fore-apprehending the suction and so the want of the rest, should stirre vp the creatures to provide and cooke their nourishment for them. For if the sense of this suction or traction were in euery part, then in the time of affamishment or thirst they would perpetually languish; and so the creature leade his life in a perpetuall disease.

This part so by Nature set out, is the vppermost mouth of the stomach, which the ancient *Grecians* as *Galen* witnesseth, called *καρδια*. And all men doe concur, that in it the Animall appetite or hunger, which is nothing else but a sense of suction, hath his peculiar residence. And this sense is exhibited in this place by two notable nerues called *Stomachici*, or the *Stomacke Nerues* arising from the sixt paire or coniugation of the Braine.

But after what manner this Animall appetite is stirred vp, *Galen* hath elegantly taught vs in his first book of *the causes of Symptoms*. For the better vnderstanding of which place, these things are first to be obserued, that the Animall appetite is double; one naturall, another depraued; to the first, these five signes or symptoms must necessarily cocurre: first, an *exhaustion* or deepe expence of the substance of the parts, next there must be in the same parts a *suction* or traction; for the exhausted parts do draw from their next neighbors & those from others, till by continuation it do come to some extreame; which extreame is the vpper mouth of the stomach where the traction ceaseth: from this traction ariseth the third signe, which is a *diuulsion* or kind of violence offered to the mouth of the stomach, which diuulsion or violence striketh the nerue, whence cometh *sense*, and from the sense the *appetite*.

In the depraued appetite, the same order and degrees of symptoms are not obserued. For in the disease called *Boulimos*, there is hunger without appetite, and in the Dog-appetite, there is appetite without hunger. In the *Boulimos* all the parts being exhausted or hunger-bit, do draw from the stomach, which on euery hand is torne and as it were launced, yet doth not that diuulsion strike the sense, and so no appetite followeth; in the mean time the other parts being defrauded of their alimēt, doe waste away and consume. The cause of this sensibility is the refrigeration of the nerue, the obstruction of the same, and the exolution or fainting away of the appetiue Faculty.

On the contrary, in the Dog-appetite there is no Inanition or emptinesse of the parts, but an exquisite sense of suction, by reason of a coole and sowre humor there impacted, and it is cured *Theorexi*, that is, by drinking of wine as *Hippocrates* witnesseth. Hence therefore it is manifest that the animall appetite is stirred vp in the mouth of the stomach, which is endued with so exquisite sense, that it is called the Organ or Instrument of touching by *Hippocrates* in his Book of *the Instruments of smelling*.

There remaineth yet one scruple, how the Appetiue faculty standing in reference to the sensitive, should haue his seate in the mouth of the stomach, seeing it is of al hands determined that the seate of all the Animall faculties is in the braine. The answer is easy & at hand, to wit, that the faculty it selfe is in the braine, but the work, efficacy & action thereof in the stomach. So the faculty of seeing is in the braine, but the sight is accomplished in the eye. The moouing faculty is likewise in the braine, yet is the Muscle the immediate organ of voluntary motion.

If any man object that the Luer is the seate of the Appetiue faculty, we answer that the

QUEST. IX.

Of the situation and consent of the uppermost mouth of the stomacke.

THe difference or controuersie concerning the seite of this Orifice is neither light nor vnprofitable, because the resolution thereof stineth the strife among the Physicians concerning the application of Topicall or locall medicines.

The seite of the vpper orifice.

Hippocrates
Lib. de art. med.
lib. sect. 3.

Where to apply locall medicines.

The reason of the paine at the breast bone, when the mouth of the stomack is affected.

The consent of the mouth of the stomacke, with the heart & the braine.

Why vomitings follow the wounds of the braine.
Galen.

All men doe agree that it inclineth rather to the left hand then to the right, but the question is, whether it be neerer the spine of the back, or the gristle and blade of the breast. Some thinke that Nature framed this gristle to be a defence for it and for no other cause, & therefore hath placed it there-under: for say they, those that vomit or reach, doe finde a paine at this gristle and none at the spine or racke of the back. And Hippocrates conceiueth that the extuberation or distention of the stomack at the orifice is not backward but forward; whereas he saith, *That the repletion of the stomack is a direction for broken ribbes.* Wee with Galen doe assigne the place of this orifice to be in the left part toward the spine, not that it lieth or resteth vpon it as the gullet doeth, but because it commeth neerer to the spine then to the breast-blade. And therefore it is that when the gullet or the vpper orifice are affected; we thinke it fit to apply locall medicines both to the back-part and to the fore-part. That that was propounded concerning the paine of them that reach to vomit, and the direction for the ribs, is to be referred to the bottome, and not to the vpper mouth of the stomack; for as we haue obserued, the meate which we eate is not contained in his mouths or orificies but in his cavity, which we doe not deny doeth rather leane to the breast-blade then to the spine.

But the reason why the breast bone is payned when the vpper orifice is affected is meerly Anatomical; the midriffe being tyed to the bone, and the mouth of the stomack adhering to the large passage made in the midriffe for his conueiance thereout; and therefore the breast-blade is payned by this continuity, because paines are rather felt in the extremities or ends then in the middest, as is to be seene in stretched membranes. Concerning the sympathy or consent of this orifice with the heart and membranes of the braine, Hippocrates & Galen are very plentifull; for this mouth being affected, the syncope or sounding, the exolution or fainting of the spirits, and such like symptoms doe ouertake vs as when the heart it selfe suffereth violence, whence this part amongst the ancients as we said before, is called *capula*. In wounds of the head, the skull being either broke or shiuered, & the *dura meninx* or thicker membrane of the braine exposed or laid open to the ayre, which is vncouth or strange vnto it, the Patient presently vomiteth yellow and *Eruginous* or greene choler, because the stomack by reason of society, is drawn into consent and sympathizeth with the membrane, as well because of the similitude and likenesse of the substance, as also of the community of vessels, which are the chiefe causes of consent or sympathy; as Galen obserueth in his *Commentaries* vpon the first section of the 3. book of Hippocrates *Epidemia*. For you must know that *Eruginous* or greene choler is only ingendred and contained in the stomacke.

QUEST. X.

Whether the Chylus be made by the heat, or by the forme of the Stomack: and why the Stomack doth not breede foure substances and excrements as well as the Liver.

Why the stomacke is incompassed with warme parts.

He remouing of these two obstacles and dissolution of the doubts arising in them shall neede no great curiosity; the first wee will determine thus. The Chylus is formed not so much by the power of the heate, as by the ingenite property of the stomacke. True it is that all concoction is accomplished by the help and assistance of heate, and therefore Nature hath provided that the stomacke should be cherished and comforted on every side, aboue and below, on the right hand and on the left, before and behinde; but this concoction belongeth not to the heate as it is heate (for by that reason fiery and aguish heate which corrupteth all things, should be

be the cause of concoction) but as it is the instrument of the soule. For that which wee call chylyfication or making of the Chylus, proceedeth alone from the *forme* and proprietie of the stomacke, because in other parts saving this, the naturall heate though it be very strong and intense yet doth not chylyfie. Now why the stomacke as the Liuer doeth not beget or breede foure kinds of substances, there may bee a double reason assigned; one from the matter, another from the efficient.

A double reason why the stomack breedeth not 4. substances.

The Efficient or working cause is naturall heate, which if it be very strong, it powerfully and effectually or really separateth *Heterogenia*, that is partes that are vnlike or of different natures. But all men know that the Liuer is so much hotter then the stomacke, as bloudy parts are hotter then those without bloud; for the Liuer is a fleshy bowell and the stomack a membranous; wherefore the heate of the Liuer diuideth the Aliment into more particles, which the weake heat of the stomacke cannot doe.

The first from the efficient.

To this efficacy of the Efficient may be added as we sayd the disposition of the matter; for liquid things are more easily altered then solid: now the stomacke receiueth the Aliment when it is solide which with great labour it boyleth, breaketh, and altereth; but the Liuer receiueth it already attenuated and wrought into an equality, when it is no great labor to separate the dissimilar and *Heterogenic* parts, or being separated to driue them into their proper receptacles.

The 2. from the disposition of the matter.

QUEST. XI.

whether the Stomacke be nourished by the Chylus or by Blood.

Inally, that we may passe from the stomack, we will end with that great contro-
uersie which is amongst Physitians concerning his nourishment. Some there are who thinke that the Stomack and the Guttes are nourished by the Chylus, some by crude or raw blood not laboured in the *Parenchyma* or substance of the Liuer; but only hauing an inchoated mitigation in the branches of the port or gate veine.

Divers opinions about the nourishment of the stomacke.

Auicenna thought that the vpper coate was nourished with blood and the inner with Chylus. *Zoara* writeth that the vpper or neruous part is nourished with the Chylus and the lower which is more fleshy, with blood. We with *Galen* determine, that the whole stomack as all other membranes is nourished with pure blood, which hath had his utmost and perfect elaboration in the Liuer. For the prooffe whereof beside the vulgar and ouerworn arguments which Physitians vse, these of no light moment may be cast vnto the heape.

Auicenna.

Zoara.
Galen.

The first is taken from Dissection, because through all the coates of the stomacke and his two orificies, there appeare notable and abundant veines diuersly dispersed, which doubtlesse were not idely or in vaine ordayned by Nature, neither yet to transport the Chylus to the hollownes of the Liuer, howsoeuer *Baubine* be conceited, (vnlesse happely in extremitie of hunger) for then they should carry it rawe, not yet hauing receiued his perfection in the guts.

1. Reason.

Moreover if the veines were especially appointed for the transportation of the Chylus, it being made rather in the bottome then at the sides or top of the stomack, there should haue been more veines and more conspicuous in the bottome then in the top, which experience teacheth vs to be otherwise; for the whole basis and circumference of the vpper mouth is incompassed with an ample vessel called *Coronaria stomachica* or the garland vein of the stomack, because the coats of the orifices are thicker then those of the bottome, and therefore neede more plentifull Aliment. We resoluue therefore that these veines were ordained for the nourishment of the stomacke; but wee will vnder-prop this reason with a stronger.

2. Reason.

In the Chylus although it be laudable and well disposed, yet there remaine some vnprofitable and excrementitious parts; to wit, Choler, Melancholy, and whay or vrine, which cannot be separated or purged therefrom but by the heate of the Liuer. Now nothing can nourish perfectly vnlesse it be cleansed from those recrements: how therefore shall the Chylus not yet defoecated, be sayd to be conuenient Aliment for the stomacke? And this *Galen* seemeth to intimate when he sayth; *That nothing can perfectly nourish which hath not passed through all the concoctions.*

Galen.

A third argument to proue our assertion, that the stomacke is nourished by blood, is because those creatures that mew themselves vp at wintre in holes and rockes and such secret places

3. Reason.

places are nourished by blood, and not by Chylus, because at that time they feed not at all. The infant likewise as long as it is contained in the womb, hath his stomacke without controuersie nourished with pure blood brought vnto it by the vmbilical vein. Hereto *Valerius* in his Controuersies answers, that the Stomacke is nourished by the more crude or rawe part of the Mothers blood which is not much vnlike vnto Chylus. But as well might he say, that the Braine, the Bones and all the Membranes haue their refection therefrom, because they are nourished with Flegmatick and crude blood.

Furthermore, in great weakenesse of the stomacke and loathing of meate, that the patient should not vterly consume, wee prescribe nourishing Clifters of the best sortes of flesh, Capons, Partridges, and such like boyled to a broath. This liquor arieth not at the stomacke, but is sucked away by the Veines of the guts, and transported to the Liuer where it attaineth the forme of blood, and after being carried in the veines as in water-courses vnto the parts, it watereth, nourisheth and refresheth them. Nowe who will say, that at this time the stomacke is nourished by Chylus when there is no chylification therein? and yet I hope they will not deny that it is then also nourished as well as the other parts. Finally this opinion of ours may bee demonstrated by the similitude or correspondencie of the nourishment of other parts like vnto it; and therefore seeing all the membranous parts of the body are nourished by blood, why should the Stomacke among all the rest bee exempted? We do therefore conclude, that the Stomacke is nourished by blood, and that not onely having an initiation or rudiment in the Port veines, but laboured and perfected by the power and efficacy of the *Parenchyma* or substance of the Liuer.

Notwithstanding these things are so, some learned men among the new Writers, as *Thomas Veiga* and *Laurentius Iobertus* doe thinke, and mightily contend by manie arguments, that the Stomacke should be nourished by the thinner part of the Chylus, to which we will make some satisfaction.

In the first place they oppose the authority of *Galen*, who in his third Booke of the naturall faculties, and in the fourth of the Vse of parts in plaine words teacheth, that the stomacke hath his refection and nourishment by the Chylus. For answer to *Galen*, out of *Galen* we say, that there is a double nourishment; the one perfect, which is *Assimilation*, the last vphot and accomplishment of natures endeaours in this kinde; the other imperfect, as it were the *Ape* or imitator of the former, which is a kind of delight the part conceiuet from a quality that is of kinne vnto it; and this kinde of refection *Galen* calleth *Lascina*, as if the entertainment were rather for dalliance then procreation. And in this latter kinde the stomacke according to *Galen* is refreshed by the Chylus, not in the former.

Secondly, they obiekt that no branches of the Hollowe veine are deriued vnto the stomacke and the guts, but onely certaine small rills from the Gate-veine, who haue but one vse, which is, to transport the Chylus vnto the Liuer, and therefore (say they) the organs or instruments of nutrition are not nourished with blood perfected in the Liuer for (there is no commerce by vessels betweene them) but onely with Chylus. This Argument I take to be very ydle and friuolous: for if onely the riuersets or channels of the Hollow-vein did containe Alimentary blood, and the branches of the Gate-veine were only ordayned to transport the Chylus, then should the Spleene, the Mesentery, and the Kell bee likewise nourished with Chylus, because they haue no allowance of Vessels from the hollow vein. In like manner the great guts should assimilate Chylus into their nourishment, in which it is certaine there is nothing conteyned but the excrements, the iuice being before drawn from them.

Their third Argument is taken from Dissection, because (say they) the Veines do onely open at the Stomacke, and are not disseminated through his coates, and therefore they suck iuice from it, rather then nourish it with their owne allowance. But (alas the while) what new Anatomy is this? Is there not a double Gastrick or Stomacke-veyne stretched through all the Coates of the same? Beleue me, the insertion of these and other veines is altogether alike.

The fourth Argument is that of the learned *Veiga*. The Organs (saith hee) of the first concoction are more ignoble, and are framed of farre impurer iuyce then the Flesh; and therefore it is fit they should be nourished also with impurer iuyce, before it is concocted in the Liuer. But this reason drawes many absurdities with it; for the bones are more ignoble then the stomacke or the guts, and colder by farre, and yet are nourished by blood conueyed vnto them from the Liuer by the Hollow-Veine, yea, and almost all the Mem-

branes

branes colde and base though they be, do draw that blood and no other, which is perfectly concocted in the *Livers parenchyma* or substance.

The Fifth reason followeth, which they put great confidence in, and it is such. If the Stomacke bee not nourished with Chylus, how then commeth it to passe, that presently vpon the taking of Meate both hunger and thirst is appeased? Wee answer, that there is a Double hunger, one Naturall and another Animall: the Naturall is without sense, and placed in the particular parts of the bodye. The Animall is with most exquisite sense, and proper onely vnto the Stomacke, yea especiallie to the mouth thereof: the first is appeased onely by Assimilation; the latter, because it is a sense or apprehension of Divulsion, when the Divulsion ceaseth, then it is also appeased, Vpon the eating of meate, the Animall hunger of the Stomacke presently falleth, because the stomacke being filled, his divulsion and compression ceaseth: but the Naturall hunger is indeede appeased some-what when the inwarde coates are moystened as it were with a pleasant Dewe, yet not altogether before perfect Assimilation, which is not accomplished without some distance or interposition of time. Thus farre their Arguments.

Now because *Galen* saith, that *what soeuer nourisheth must passe through three concoctions: Veiga* to saue his owne Stake, would interpret *Galen* as if hee meant this onlie of the nourishment of fleshie parts, when as in a thousand places he witnesseth that blood alone is the fit and conuenient Aliment of all the parts.

Againe, to establish his false Opinion, hee coyneth verie cunninglie, a three-folde Concoction in the nourishment of the Stomacke. The first (sayth hee) is Chilification, which is made in the bottome: the second, is Sanguification and perfourmed in his Veynes: the third, is Assimilation, which is accomplished in his coates, So that his pleasure forsooth is, that the Chylus is sucked by the Veynes, in them they are turned into Blood, and from them againe are they drawne by the Stomacke for his nourishment.

But in this Triple faigned Concoction, there is a threefolde errour. For first, it is most certaine that the blood by no meanes becommeth redde but by contaction or touching the *Parenchyma* or Flesh of the *Liver*. Againe, I see no reason why the Chylus shoulde bee rather drawne by the Veynes then by the Coates of the Stomacke, if there bee so great similitude of substance betwixt the Chylus and his Membranes.

Finally, if the Chylus were to bee drawne by the Veynes, and there did get some rudiment of blood, it followeth necessarily that the Stomacke is not immediately nourished by Chylus but by blood. And so much concerning the Appetite, Scituation, and Consent of the mouth of the Stomacke, as also of the Chylification and nourishment of the Stomacke it selfe. Now proceede we to the *Liver*.

QUEST. XII.

What is the Nature of a spirit, and whether the *Liner* do breede or get a Naturall spirit.

BEcause in the Schoole of Physitians the Controuersie concerning the naturall spirits is sufficiently bandyed, I wil not spend much time in a thing so notorious; onely for their satisfaction to whom these subtilties are most strange and lesse obuious, I will giue a taste or short assay concerning the nature of spirits.

Galen in his sixt Booke of the *Use of parts*, defineth a spirit to bee *A certaine exhalation of benigne or well disposed blood*: The Stoickes call it, *The tie or band of the soule and the bodie*; for the distance is not so great betweene the highest Heaven and the lowest Earth, as is the difference betwixt the Soule and the Bodye. It was therefore verie necessary that a spirit should bee created, by whose intermediate Nature, (as it were by a strong though not indissoluble bonde) the Diuine soule might bee tyed to the bodie of Earth. Wherefore there are some that say it is an Aetheriall body, the seat & band of heate & faculty, and the prime instrument whereby all the functions of the soule are performed. But to say as the truth is, it is called Aetheriall onely Analogically, because of his tenuity and diuine manner of working, for by his nature and in his originall he is meereley Elementary. Our definition of a spirit shall be this, *A subtile and thinne body alwayes moonable, engendred*

Spirit.
Reasons.

That it is a body Hippocrates witnesseth, when he reckons it in the number of those things whereof the body is compounded; for he diuideth the body into *Continentia*, *contenta*, & *impetum facientia*, that is, into parts containing, contained, and such as moue with a kinde of impetuous violence. Another argument that it is corporeall, is, because it stands in neede of a channell or passage wherein it may be transported, because it distendeth the parts in which it is entertained and occupieth a place; for when the creature is dead, both the ball of the eye is corrugated or wrinkled, and the Membranes thereof doe also fall, being no more illustrated by the beames of the spirits. It is therefore a body, but the finest and subtillest substance that is in this Little world. For as the winde it passeth and repasseth at his pleasure, vnscene, but not vnfelt; for the force and incurfion thereof is not without a kinde of violence: so the seede although it be thicke and viscid, yet passeth thorough vessels which haue no manifest cavitie; the reason is because it is full and as it were hoven with spirits. Galen in his third Booke of *Naturall Faculties*, saith, *That blood is thin, vapour thinner, and Spirits thinnest of all.*

I haide moreover, that it was alwayes in motion, for the spirits are continually moued, not by another onely as the humors (which whether they be drawne or driuen are alwayes moued by a power without themselves,) but also of themselves, that is, by an inbred principle of their owne. So that there is a double original of the spirits motion, one homebred, another but a stranger; by the homebred principle they are moued as the flame vpward and downward, as Galen teacheth. Upward, because light; for they are fiery and airy: and downe-ward toward their nourishment. If either of these motions bee hindred, the spirit is corrupted, and that by consumption or extinction; by consumption for want of nourishment when it cannot moue downward; by extinction from his contraries, when it is choaked by cold and moysture because it cannot moue upwards. Again they are moued by an externall principle, when they are Drawn hither or Driuenthither. They are driuen, the Naturall from the Liuer, the Vitall from the heart in his *Systole*, the Animall from the Braine when it is compressed. They are drawne, the naturall by the veines, the vitall by the particular parts together with the Arteriall blood; the Animall verie rarely, vnlesse a part be affected either with paine or pleasure. For in such a case neyther dooth the vehemency of the object suffer the faculty to rest, nor the heate cease to draw the spirits vnto it. The spirits therefore haue a body mouable.

It followeth in the definition, that they are engendred of blood and a thin vapour; so that they haue a double matter, an exhalation of the blood and aire; and therefore it is, that all our spirits are cherished, preserued and nourished by aire and blood.

The last part of the definition designeth the vse of the Spirits, as being the last and finall cause for which they were ordained. For the spirits are the vehicles or carriages, not of the soule, but of the faculties thereof; for if the Vessels, Veines, Arteries, or Nerves be tyed, the life motion and sense of the parts to which these vessels passe, do instantly abate and are in short time vtterly extinguished vpon the interception of the spirits, not of the faculties themselves which are incorporeall, because the band or tye dooth neither interrupt the continuity of the vessell with his originall, neither yet his naturall disposition. And this is the nature of spirits in generall.

Now some spirits are ingenit or in-bred, which are so many in number as there are seuerall kinds and sortes of parts: some influent, which flowe as it were from diuers Fountaines, and serue to rowze and raise vp the sleepey and sluggish operations of the former. Concerning the number of the influent spirits, Physicians are at great difference among themselves. *Argenterius* thinketh that there is but one sort of spirits, because there is but one soule and that hauing but one organ, one blood and one ayre which is breathed in. But the Ancients farre more acutely haue recorded three manner of spirits, because there are three faculties of the soule, the Naturall, the Vitall, and the Animall; three principles, the Braine, the Heart, and the Liuer; and three kinde of Vessels, Veines, Arteries, and Sinnewes.

That there is an Animall spirit, beside that Galen inculcath it in sundry places, many reasons do cunct. For to what purpose else was the braine hollowed or bowed into so many arches? To what purpose are those intricate mazes and labyrinthes of small Arteries which in the Braine we call *rete mirabile*, the wonderfull Net? And why are the sinewes

stored when it i

propagated into so many branches? But of this we shall have occasion to speake more hereafter, as also of the vitall which no man yet euer opposed, and of which the Poet maketh mention, calling it a *Diuinity*:

Est Deus in nobis, agitante calescimus illo.

In vs there is spirit seated,

And by his motion we are heated.

Onely concerning the naturall spirit there hath been some difference, many labouring to blot his name out of the rowle; whose arguments we will here cite before the tribunall of Reason to see how they acquite themselves. First they say that the naturall faculty needeth no vehicle or westage, because it is inbred in euery part, for which they auouch *Galen*. Again, there is no matter whereof this naturall spirit should be made, because there be no vessels whereby ayre may be conueyed vnto the Liuer; neither is there any place for his generation, there being no such cauities in the Liuer as are in the Heart & the braine. Adde hereto that there be no currents or channels to be found whereby it should be led through the body: for the coates of the veines are too thinne to hold or contain an aetheriall Spirit. And truly *Herophilus* well conceiteth that therefore the Artery is manifolde (sixe fold saith he) thicker then the veine, because it was made to containe the Spirits, which by reason of their tenuity, if they had not bene inclosed within stronger wals, would easily haue vanished away.

Moreouer, seeing the spirits as *Hippocrates* sayth, haue in them a kind of nimble violence and impetuous motion, if they were contained within the veines, they would make the veines to beate as do the arteries. Finally, if it be granted that the spirits doe passe and repasse through the veines, yet with what nourishment shall they bee preferred? For heate sayth the great *Dictator Hippocrates* is nourished by moderate cold; now there is no ayre led vnto the veines to serue that turne.

These and such like are the arguments whereby they casse this naturall spirit, which if they be weighed in equal balances will be found too light to sway an established iudgement. For first, *Galen* doth not absolutely deny that there is a Naturall spirit, onely he casteth in a doubt as it were by the by, as also he doeth concerning the vitall spirit, in the fifth chapter of the 12. book of his *Method*, when yet notwithstanding it is beyond all controuersy that it is contained in the arteries. But more plainly in the sixt of the *Use of Parts*, he writeth that there is a spirit contained in the veines; yet are there but few of them, and those darke as he sayeth and cloudy. Wee confesse that there is a naturall faculty bred and seated in euery part, but because the heate and naturall spirit of the parts wherein this inbredde faculty doth consist is but vncertaine like a fugitiue, and dull or stupid; it standeth in neede of another influent yet like vnto it selfe, whereby it might be stirred vp, established, and from a potentiall vertue brought into an operative act.

The Arabians imagine that the blood is transported and guided through the whole body vnder the conduct of the spirit; for although euery part like a Load-stone doe draw vnto it selfe such iuyce as is familiar vnto it, yet if the distance of place be too great, neither can the Load-stone draw yron, nor Amber chaffe, nor the part his nourishment. To their second argument that there wanteth nourishment both for the generation and preservation of this spirit because no ayre is conueyed vnto the Liuer; we answer with *Hippocrates*, that all bodies are *Transpirable* and *Transfluxible*, that is, so open to the ayre as that it may easily passe and repasse through them, though not so abundantly as it doth by the winde-pipe, of which abundance there is no neede, because this thicke and cloudy spirit needeth but a little ayre for his refectiō, which is supplied by transpiration. This transpiration is made in the hollow parts of the Liuer by the Arteries. In the round or gibbous parts although there be no Arteries, yet the midriffe with his continuall motion as it were with a fanne, ventilateth or fanneth, not the Liuer onely, but all the entralles.

Thirdly, whereas they say there is no cauity, no Cisterne, no place for generation of such a spirit in the Liuer; it is truly a very bold conclusion. But let vs stick to them with as great confidence hauing *Galen* on our sides equialent to a whole army of such inexperienced *Tyrones*. It was not necessary saith he that there should be any cauity or cell in the Liuer such as are in the heart, because those bowelles only which were either to receiue from others, are to affoorde and impart together-ward and at once a plentifull and abundant source of matter stood in neede of an ample cauity wherein it would be either treasured & stored when it is receiued, or wrought and framed when it is to be conueyed. The Conclusion.

rit as it is very fine and thinne and therefore quickly exhausted; so it behoued that it should as sodainly be regenerated that there might neither want plenty for necessity, nor abundance for sodain expence: it was therefore necessary that it should haue a large cavitie or Cauldron wherein it should be boyled and prepared for vse; as wee see Nature prouided large and ample vessels for the nourishment of the Lungs, because of their continuall motion, which requireth a supply answerable to the expence: but the naturall spirit as it cannot so sodainly spend it selfe, so there was no neede of any abundant affluence thereof, & therefore the beds or webs of the veines were sufficient for his generation.

Fourthly, whereas they say that the thinne coates of the veines are too weake to guide and safe-conduct the naturall spirit; we answere in a word, that a thicke and grosse substance or dull prisoner is easily held in durance.

To the fifth argument we answer, that the veines are therefore not moued, because the faculty of pulsation is not deriued vnto them from the heart; for we doe not thinke that the arteries are moued by the heate and spirits which they containe, but only by a vitall faculty streaming through them by irradiation from the heart, as we shall prooue hereafter.

Finally, they aske how we thinke these spirits should be nourished? We answere, that it is by transpiration which preferueth, refresheth, & maintaineth them, for euery veine hath his artery accompanying him continually, beside the manifold imbracements and inoculations, whereby they are as it were wedded one vnto another. We conclude therefore that there is a naturall spirit, the vehicle or guide of the naturall faculty and of the thicker sort of the blood which is from the Liuer diffused into the whole body.

QUEST. XIII.

Whether the Bladder doe draw the Choler vnto it for his Nourishment.

The seate of the bladder of gall.

Galen.
Falopius.

That there is a small Bladder tied to the hollow part of the Liuer, replenished with a yellow bitter iuyce which wee call *Choler* or *Gall*; there is no man ignorant who hath touched *Anatomy* as they say, but with his vpper lip. But whether this iuyce doe passe vnto the Bladder of it owne accord, or be drawne by the Bladder, or ablegated and sent by the Liuer, it is not altogether so manifest. That a meere *Elementary forme* should leade it by a kind of instinct or Naturall choice (for some choices may be naturall) or election vnto that place, I thinke few men of reason will auouch. More likely it is that it is either drawne or driuen; *Galen* is for both, so is reason also; although *Falopius* that subtle and ocular *Anatomist*, contendeth that it is onely driuen from the Liuer and not drawne by the Bladder, to whome and his arguments we will set our feet in the next exercise.

That the choler is driuen from the liuer.

Why the bladder of gall is fastned to the Liuer.
That it is drawne by the bladder of gall.
Galen.

That the choler is driuen from the Liuer, the very nature of the iuyce doeth sufficiently proue; it is an excrement, in his whole nature and quality hurtfull and noxious, to the Liuer especially; and therefore it ought to be auoided and that sooner and with more expedition, then the other two excrements, because his sharpe prouocations are more offensive, & for that reason the receptacle of choler is tyed or fastned close vpon the cavity of the liuer, but the spleene and the Kidneyes which receiue the other two, are set further off.

Againe that this choler is drawn by the bladder of gall, *Galen* teacheth in his 4. & 5. books of the *vse of Parts*; and beside, the fashion and conformation of the bladder it selfe and his passages doe aboundantly perswade vs therunto; for because there be diuers choler-conduits bending rather down to the guts then to the bladder whose scite is higher; vnlesse the bladder had a peculiar and in-bred traction; vndoubtedly the choler would rather fall downe into the guts then arise vnto the bladder. The bladder therefore draweth this bitter iuyce, and that sincere without admixtion of any more benigne or pleasant humor.

Robert. his opinion.

His reasons.
Galen.

But whether this traction of the Choler by the vesicle or Bladder bee for nourishment, or from a certaine consanguinity betwixt their qualities, or rather by a hidden and vknown propriety, it hath bene a question of old, and yet is not determined vpon record. *Laurentius Iobertus* sets forth a paradox concerning this matter, wherein hee determineth that this Bladder is nourished by Gall, as the Spleene by Melancholy, and the Kidneyes by *Serous* or whaey blood, which opinion may bee established by these reasons. First, it is an axiome in Philosophy and Physicke, which *Galen* often inculcateth and vrgeth in his bookes

bookes of naturall faculties, *That nothing draweth for the drawing it selfe, but for the enioying of that which is drawne*, that is to say, all traction hath some particular end for which it was instituted.

Now the bladder draweth the choler: to what end? No doubt for his nourishment; and this the colour of the bladder perswadeth, which is altogether yellow by reason of the choler assimilated vnto it. Secondly, the Veines that are dispersed and disseminated through the coates of the Vesicle are so small and hairy, that a mans eye can scarce finde them out, and therefore by them the bladder, especially the inner part cannot be nourished. Thirdly, *Galen* witnesseth that the Lungs are nourished by choler, why then may not the Bladder a more ignoble part bee nourished with more impure choler? These and such like are their arguments, who imagine that the traction of the choler is for the nourishment of the bladder.

On the contrary, we being guided by authority, and established by *Galen*s weighty arguments, do not thinke that the Bladder is nourished by Gall but by blood, conducted or led vnto it by the Veines; and that this traction whereof we haue spoken, hath some other end for which it is vnderaken and not for nourishment. *Galen* in his 5. booke of the vse of Parts & the 7. chapter writeth, that both the Bladders because they draw a sincere excrement altogether vnprofitable for nourishment, do stand in neede of bloody vessels or vessels full of blood by which they may be nourished. And againe in the 12. chapter of the 5. booke, he askes the Question why the stomack & the guts haue double coates, and both the bladders but one, and that proper? Hee answereth himselfe thus. Because in the Bladders there was to be no concoction made of those things contained in them; If no concoction of the substance, then no nourishment by the same. To these authorities reason also lendeth her assistance on this manner. All nourishment is by assimilation; but choler cannot be assimilated because it is an excrement; not offensive onely by reason of his quantity, but also in his quality distastfull and vnfauoury. The conclusion we leaue for them to gather who hold the contrary.

A second reason may be, because Nature neuer attempteth any thing in vaine, why then were the two Cysticke twinnes or veines which leade vnto this bladder ordained, if it were not for his nourishment? I confesse they are very small (though our grauer hath cur them large) but yet great enough for the nourishment of so small and vnbloody a part; and so much for the establishing of the truth.

Let vs now another while make answer to the arguments of our aduersaries aboue alleged. The bladder of choler, say they, is yellowish; and that cometh by the assimilation of choler. The conclusion hageth not wel vpon the proposition. For the Colon also in that place where it toucheth the Bladder of Gall groweth yellowish by the transudation or sweating through of the yellow iuice abounding therein; yet who will say for all that, that the Colon is nourished by choler? And whereas they compare the nourishment of the Lungs and the bladder of gal, they forget that choler is one thing and cholerick blood another. The lungs indeede are nourished with cholericke blood, that is very thin and laboured to a height of heate in the left ventricle of the heart, but with excrementious choler no part is nourished.

If they object that the spleene and the kidneies are nourished, the one with excrementitious and foeculent blood, the other with *Serous* & whey; we answer, that we will make any man iudge whether there be the like reason of all these parts, the Kidneies, the Spleene, and this Bladder. For albeit the Spleene doth draw vnto it foeculent blood, and the Kidneyes a *Serous* excrement, yet are not these pure and vnmixed; for their vessels, to wit, the Spleenick branch and the Emulgent veines are very large. Now we may remember that *Galen* saith, that those parts which draw any iuice through ample & large orificies cannot draw it pure and sincere, and therefore the Spleene and the kidneies do draw their excrements mingled with much benigne and alimentary blood, with which blood they are nourished, but the vnfauoury excrement they separate and auoid. But the Bladder draweth vnto it selfe pure and sincere choler, not mixed or adulterated with any other humor, as well because the narrowness of the passage wil not admit any thing thicker, as also for that the attractiō is stirred vp by a familiarity betwixt the bladder and the humour. It remaineth therefore cleared as we hope, that the bladder drawes not the choler for his nourishment.

If it be demanded why then it draweth it? We answer, that *Galen* thought it was by reason of a familiarity and similitude betweene them to vs vnknowne, it may bee also incomprehensible. For as the Load-stone draweth yron, and Amber chaffe; so the bladder draw-

eth choler, with whose presence it is delighted and tickled as it were with a fence of pleasure. For so he sayth in the 10. Chapter of the 5. Book of the *use of Parts*; *Choler is drawn by the bladder, by reason of a communion of qualities.* For as long as the Creature is aliue, though he liue very long, yet alwayes there is choler contained in the bladder of Gall, yea and after death, if wee will keepe the Gall long, wee may preferue it best in his own bladder; neither of them suffering violence by other in any reasonable tract of time, for those things that are familiar and as it were akin, will not offer violence one to another.

If any queasie stomacke shall aske the question how the bladder can be delighted with such an excrement whose rage and acrimony is so fierce that if it stay but a little in the guts it vlceraeth them, and if it be poured into the habit of the body, by irritating the pannicle or fleshy membrane it stirreth vp a rigour or general shivering; how the bladder which is membranous & therefore of exquisite sence, should not feele that acrimony or be offended with so impure a humor? We answer first with *Lucretius*, *That Nature couereth many things under a sacred veyle*, and that in this great vniuerse the sympathies and antipathies of things are secret and wonderfull. Againe, the Bladder is delighted with the presence of the choler, and therefore is not hurt by his acrimonie. Happly also because it is vsed to it, it is not afflicted by it; so those men that are accustomed to poyson, doe not feele the poysonous power thereof, and a drop of liquor strangeth well-nigh the Arterie, whereas full cups delight the stomacke. Againe, the stomacke is pained with a little ayre, and the guts torne thereby with cruell torments, but the Lungs because they are accustomed vnto it, do swallow the aire in great aboundance and are refreshed thereby.

Those men that will not admit of this familiarity or acquaintance betweene the choler and the bladder, doe referre the cause of this Traction to the necessity and prouidence of the vniuersall Nature; to wit, that the blood may be purged, least being defiled with such an excrement, it should become vnprofitable for nourishment.

QUEST. XIII.

Of the passages by which the Choler is purged, against Falopius.

The commendation of Falopius.

Dangerous to vary from the ancients.

The two passages of choler. Falopius his opinion.

Arguments against Falopius.

Abruel Falopius, the most acute and subtle Anatomist of our age, hath deserved exceeding wel in opening vnto vs many things which in the former ages were not knowne. He first of all men did accurately describe the History of a mans Eie, & obserued that gristly body which they call *Troclea*. He first found out the yarde of the wombe called *Clitoris*, beside the manifold nicities foulded as it were in a thousand difficulties, which he hath manifested and brought to light in the Histories of the muscles, the veines, and the sinews; yet notwithstanding this great learned man in his Assignment of the use of the bladder of gal, whilest he describeth the passages whereby the choler is led, in falling frō the authority of the ancients, falleth into an error wherof he cannot be excused.

The ancient opinion and indeede the very truth is, that there are two passages of the gal, one distributed into the Liuer with abundant shootes, the other passeth from the vesicle vnto the guts. By the first the bladder draweth the gall vnto it selfe; by the second it dischargeth it again into the *duodenum*. Falopius on the contrary, conceiteth that those passages of choler which are disseminated through the liuer runne directly not vnto the bladder but to the *duodenum*, and doe continually thrust out the choler thereinto. And because it hapneth full oft, that the guts are either distended with winde, or in the time of distribution are full of Chylus; so that the passage or out-let ordained for the auoyding of choler is intercluded or shut vp; least, saith he, the choler, should flow back and returne vpon the Liuer to defile the blood, Nature hath framed the bladder as it were a diuerticle or cisterne out of the way, wherein the choler might be gathered and reserued together, whilest the out-let in the *duodenum* should be opened.

Wherefore there bee two things which Falopius would haue; the first that the Choler passeth directly from the Liuer to the *duodenum*; the second that the Bladder draweth not choler, but that it returneth thither from the guts when they are distended. Which two assertions, by the fauour of this learned man, we cannot subscribe vnto; because we thinke that we are able to demonstrate the contrary both by reason and sence, the two most certaine Iudges and determiners of al controuersies. First therefore we say and lay as a ground, that

that in the whole frame and structure of the body there is nothing done or generated as accedentary, but onely vpon certaine ground and necessary vse. Now the vse assigned to the bladder by *Falopius* is accedentarie and casuall, for it is not perpetuall that the guts are distended with winde and their passages intercluded; but this happeneth rarely and but to some bodies and those of good constitution. Hence it will follow that the bladder must be vnprofitable, and idly framed by nature, which true and solid Philosophy wil neuer grant. For Nature at no time endeouureth against the causes of diseases, but against such as doe daily and necessarily happen. For it was the originall determination of the great artificer of this noble *Fabrick*, to create a sound and not a sickly habitation for the soule; and therefore he generated the parts at the first hand for themselves, and not afterward or at aduenture, albeit one and the same particle haue many and diuerse by-vses.

Nature ende-
uoureth a
sound body
not a sickly.

The second engine which we conceiue these paper walles cannot withstand, shal be this, that it is necessary that the *Bilious* excrement should passe vnto the Bladder before it went to the out-let in the *duodenum*. For if it should flowe by degrees and perpetuall vnto the guts, it would not moue them to excretion, because a little choler and that falling by drops, would haue beene too weake for this motion. But because it is drawn by the bladder, there- in gathered, and at length abundantly and at once powred forth into the waies of the ex- crements, it moueth them to excretion by certaine distance & with a kinde of suddainesse.

The cause of
euacuations.

Thirdly, vnlesse we admit the Traction of the bladder, and a propriety whereby it is con- tained & retained til a certain time, what would it haue auailed it to be separated from the blood? For if it alwaies descend directly from the Liuer to the gut, then must it be mingled againe with the Chylus and defile it; for the way is open, neither can the distribution of the Chylus as *Falopius* dreameth, interclude the passage of so thin and subtile a humor. Again, if the choler should returne vpon the bladder, onely when the passage into the *duodenum* is stopped, then should not the bladder be alwaies found full of choler, which is euermore to be seene in sound and healthy bodies. Ad hereto, that if the bladder were only provided for a diuerticle to set the choler as it were out of the way; what neede was there of so great a cavity? A little body would haue serued that turne, the first intention of Nature being not to send it thither but vnto the gut. Furthermore if the bladder had no power of Traction, why should the choler rather returne vnto it then vnto the Liuer, when the passage to the vesicle is longer, more crooked and oblique? For if there be nothing but a simple refluxion, it is most reasonable that should be by the broader and the shorter way, which seeing it is not, we conclude that it is drawne.

Finally, if the choler did only regurgitate and flow back and were not drawne, it would not be retained, but dispatched away againe in the same moment as an vnwelcome guest, & so this refluxion should be in vaine. For if it be not familiar vnto the bladder, why should it not prouoke it as it doth the guts and the stomacke?

Nature saith *Galen* vnburdneeth not the gall into the stomack because it was offensive, for if with his bare touch he moueth the guts to excretion, surely it would haue ouerthrowne the concoction of the stomack. *Galen* asketh the question why the guts haue two coates, and the bladders which containe so sharpe humors as the vrine and the choler but one apeece? he answereth himselfe, because the choler is noysome to the guts, but pleasant and famili- ar to the bladder, a little of it prouoketh the guts, and not the bladder, because they draw it not, neither is it familiar vnto them as it is vnto the bladder.

Galen his ob-
jection, cap. 4.
li. 5. de v. sup. par.

His owne an-
swer.

I thinke that the only reason which moued *Falopius* to father this conceite, was because he saw that the passage from the Liuer to the bladder was crooked or oblique, but direct and straight from the Liuer to the gut; and that therefore it could not arriue so soone at the bladder by the crooked passage as at the gut by the straight. Yet againe me thinks this argu- ment or reason should be too light to transport so wise a man; for the motion of the expul- sive faculty is one, and that of the tractive another, and the motion of the Elementary forme different from them both. That motion which followeth the Elementary forme is streight and direct, and rather followeth the shorter, more ample and straighter passages. In the mo- tion of the Tractive faculty which is from the soule, neither doth the obliquity of the pas- sages withstand it, nor the grauity or waight of that which passeth; for phlegmatick blood, although it be heauy ascendeth vnto the braine, and in the time of famine the stomacke re- calleth the thicker part of the Chylus that is passed from it. Seeing therefore the choler is drawn by the bladder, the crooked passage cannot hinder his ready obedience. Beside, the way from the Liuer to the Bladder could not be direct, because it is placed in the hollow-

ness of the Liuer, so that the passage must first descend, and then ascend. It will be objected, if the bladder do draw the choler because it is familiar vnto it, why doth it then discharge it selfe of it againe? For by the same propriety by which it draweth, it should also retaine & delight it selfe therewith. I answer, that the choler is not excluded vnlesse it be offensive either in quantity or quality; and sure it is, that by long continuance in the bladder, it becommeth more sharpe.

Now whereas it is objected by some, that the bladder draweth not the choler, because many creatures haue it not at all, they heereby conclude nothing. For where the bladder is wanting there he were wood that would say the bladder drew it; but we acknowledge this vse of drawing the choler in those creatures onely at the cauity of whose Liuer a bladder is set. That this bladder is wanting in some creatures, Aristotle writeth 2. de hist. Anim. cap. 15. The bladder of gall (saith he) in some is tyed to the Liuer, in some not: in the Hart and the Hinde it is obserued to be wanting, as also in the Horse, the Mule, the Asse, & the sea-Calf; the Harts called *Achani*, are thought to haue it in their taile; the Elephant & the Dolphin haue no gall in their liuers. In *Euboea Chalcide* an Island in the midland Sea neere Greece, the Cattle haue none; in *Naxos* they haue it double and very large. Finally, if as *Falopius* thinketh, it be so likely that the choler is at first hand led away from the Liuer to the gut because that passage is the shorter, let him giue me leaue to retort vpon him his owne weapon. It shall therefore, say I, retorne from the gut vnto the Liuer rather then to the bladder, because the passage is not so oblique, and so there will become no vse at all of the bladder, if it be onely destinated for a Diuerticle.

But let vs at length passe from reason to experience, which we will exhibite as plainly as we haue often found the same in our Dissections. I say therefore, that from the Liuer to the Bladder, there is an open or through passage and very conspicuous, but not from the Liuer to the gut. Again, from the Bladder to the *duodenum*, there passeth another hollow pipe, but none from the *duodenum* to the Liuer, and in each of these passages there are Valves which hinder the reflux of the choler. That this is so, may easily bee seene if you put a pipe or bugle into the passage of the Liuer, and then blow it, for the bladder will sooner be puffed vp then the gut, because the way is open from the Liuer to the bladder. Again if you put your Bugle into the bladder and blow it, then will the passage of the gut be distended, not that of the Liuer. So then, the choler passeth first from the Liuer to the bladder, and after from the bladder to the *duodenum*.

To conclude therefore, the bladder draweth the choler from the cauity of the Liuer, retaineth the same for a certaine time, and after in a season only knowne and appointed by Nature, dischargeth it againe into the guts. And this was the opinion of the ancient of our Art. *Hippocrates* in his fourth book of diseases, *Galen* in diuers places, and in a word the whole Schoole of Physitions haue receiued it without opposition. Now, where there is so great a consent of learned and wise men ioyned with the authority of all antiquity, I am not easily drawn to dance after the nouell musick of a wanton wit, which shall vary therefrom.

But that there may be nothing wanting in the history of these passages, it is worthy our obseruation, that the way by which the bladder emptieth himselfe, is some times found double, that is, there be two branches thereof, of which one passeth vnto the bottome of the stomacke, and the other to the *duodenum*. *Galen* made mention of both these in his second book of *Temperaments & in arte parua*: and *Vesalius* affirms that he saw it once. Sometimes this channell of choler is but one, & is by nature framed amisse, being inserted in some men into the bottome of the stomack, in others below the *duodenum*, the former sort do continually vomit choler, the later as continually auoide it by seidge; the first are called *πυρροχολοι* *Cholericke upward*, the other *πυρροχολοι κατω* *Cholericke downward*, both *cholericke* (saith *Galen* *ἐξ*, that is) *in their habite and conformation*.

To make these things more plaine, wee must obserue that according to *Hippocrates* and *Galen* there are two sorts of cholericke men, some are so by nature, some by euent or accident. By nature cholericke, is either in Temperament, or in Habite. In Temperament those are cholericke, whose Liuers are hot aboue measure; for a hot Liuer engendreth abundance of choler. In Habite those are called cholericke whose bladder of gall is so formed, that the Canell or passage of the gall runnes either to the stomacke, or the empty gut, and yet both these thus habitually cholericke, may in their temperament be Flegmaticke. There is an elegant history in *Galen*, in his Commentary vpon the second section of the book, intituled *de victus ratione in morbis acutis*, concerning *Paul* the Rhetorician, & *Eudemus* the Philosopher: the

the Rhetorician was the most part cholericke by euent, & leuerie by euent, salt and spiced. But whether they haue made question well practised in the bladder, by one meere imagination, and auoydeth choler in small twiggies, the inserted into the *duodenum* as appeareth in the hard (saith he) to cut times, if we consider the Spleene.

Here be of the Spleen, thirdly, absolutely, but the stomacke, and w of the Schooles maiefty, wisdom our bodies, wh wealth of the fam chronicum, &c. the organ of lang blood prepared & and structure of b vessels; because e dy, either double macke, the wom is in the right si one and the same hope to preuaile so ample bowels again should the tion, when one w of the melanchol vpon the bones an humor in vs, there to place ordaine away by sweats a whose arguments himselfe, partly gant and witty B thereof, that is, the nest part of the thorough the Ar

the Rhetoritian was altogether Flegmaticke, yet vexed with continuall vomitings, and for the most part costive: the Philosopher had many colericke euacuations downeward, but none by vomit. All these are called *Bilious* or cholerick by nature. There are also some cholericke by euent, that is by a temperament acquired, as by labour, watchings, anger, sharpe, salt and spiced meates.

But whether the bladder do draw and driue the choler by one and the same way, many haue made question. A certaine new writer, a great interpreter of *Hippocrates*, but not so well practised in Anatomy writeth, that there are two passages inserted into the body of the bladder, by one of which it draweth, by the other it driueth forth the gall. But these are meere imaginations; for the passage of the bladder is onely one, whereby it both draweth and auoydeth choler, though at seuerall times: yet from this common passage do spring two small twiggies, the one diuersified into the Liuer, by which it draweth onely, the other inserted into the *duodenum*, by which it onely expelleth. And this *Galen* vnderstood right well, as appeareth in the thirteenth chapter of his third booke of Naturall Faculties. *It is not hard* (saith he) *to conceine how traction and expulsion should be made by the same passage at seuerall times, if we consider that the gullet doth not onely leade meate into the stomacke, but also in vomiting casteth it out by the same way.* And thus much of the Bladder of gall, now we proceede to the Spleene.

QUEST. XV.

Concerning the vse of the Spleene against the slanderous calumniation
of Galens Aduersaries.

Here be diuers opinions as well of the Ancient as Moderne writers about the vse of the Spleene, *Erasistratus* thought it not of any great moment. *Aristotle* in his third Booke *de partibus Animalium*, confesseth it to be necessary indeede, yet not absolutely, but by euent, although he sayth it sometime draweth the excrement from the stomacke, and worketh it vnto his nourishment. Both these opinions haue beene hissed out of the Schooles of Physitians, as being neither established by reason, nor agreeing with the maiesty, wisdom, and policy of Nature, who vseth not to create any thing in the frame of our bodies, which is not necessary for the better gouernement and order of the common wealth of the same. *Alexander Aphrodisiens* sect. 2. problem, and *Aretaeus* lib. 1. *de causis & signis chronicorum*, &c. and the author of the booke *de Respiratione* do conclude, that the Spleene is the organ of sanguification, and they call it the bastard Liuer. In this, say they, is the venall blood prepared & concocted; yet doth their beleefe rest vpon coniecture, because the frame and structure of both the bowels is alike; for in both of them there are large and ample vessels; because nature vseth to make the common ministers or seruiceable parts of the body, either double, or if but single then that one is placed in the middest, as the heart, the stomacke, the wombe, the bladder, the mouth, the tongue, and the nose; now seeing the Liuer is in the right side and the Spleene in the left, they seeme to bee two organes ordained for one and the same actiō. But these bareconiectures are too weak to make a party that should hope to preuaile against a common receiued opinion. For how could Nature haue set two so ample bowels which were to serue the whole body in the midst vnder the heart, and how again should she not haue bin idle if she had mad more instruments then one for sanguification, when one was sufficient? *Rondeletius* was of opinion that the spleen is not the receptacle of the melancholy humor, because that humor remaining in his naturall integrity, is spent vpon the bones and other hard and dry parts of the body; and because there is least of that humor in vs, there is no part appointed to receiue the superfluities thereof, like as there is no place ordained to receiue the recrements of the blood, which for the most part do passe away by sweats and insensible transpiration. *Bauhin* runneth a middle course between these whose arguments we haue heard before in the history, and may receiue answere partly by himselfe, partly by the answere to others. *Plinius* a Physitian of *Poytiers* in France, in an elegant and witty Booke which he set out of the Spleene, hath deuised a new and vncouth vse thereof, that is, That in the Spleene the Vitall spirit is prepared: he meaneth that the thinnest part of the blood, which is the matter of the Vitall spirit, passeth from the Spleene thorough the Arteries into the left ventricle of the heart, where it is mingled with the aire,

Erasistratus.
Aristotle.Alexander and
Aretaeus.

Their reasons.

Confuted.

Rondeletius his
opinion.

His Reasons.

Plinius his op
nion.

His Reasons,

and perfected and so powred forth through the arteries, as it were thorough chanelles and water-courses into the body. And this new paradoxe he establisheth with reasons, which carry a shew of great strength and evidence of truth.

The matter (saith he) of the vitall spirit is double, Aire and Blood, and both these stand in neede of preparation and attenuation: the Aire is prepared in the Lungen, but the Blood not in the right side of the hart as *Galen* would haue it, because there are no manifest passages from the right to the left ventricle: not in the Lungen as *Columbus* thought, and therefore in the Spleene.

Hippocrates.

Moreover, we are perswaded (saith he) hereunto both by the structure of the Spleene it selfe, and by the Symptomes or accidents which follow those that are splenetick. For the structure, *Hippocrates* in his first booke *de morbis mulierum*, saith, that the Spleene is rare and spongy, as it were another tongue. Beside, there are innumerable foulds of Arteries therein; now these foulds are no where ordained but for a new elaboration, and therefore in the Braine is the wonderfull or admirable web formed, in the testicles many vessels, in the Liver millions of veines; wherefore it followeth that Nature hath ordained the spleen for the preparing and attenuating of vital blood. Add heereto, that al the Symptomes of splenetick persons, as a liuid or leaden colour, vnseasonable sweate, abouandance of lice, puffings or swellings of the feete, palpitations of the heart, are demonstratiue signes of a languishing or decayed heate and impure spirits.

Florus opinion
Confuted.

The probability of these arguments hath made many to stagger in their resolution concerning this point, and yet notwithstanding if they be called to the touch-stone, wee imagine they will proue no current Coine. For how may it be that the vitall spirit prepared in the webs of the Spleene, should be conueyed by the great Artery vnto the left Ventricle of the heart, when at his orifice there are three valves or membranes shut without & open within, which hinder the ingresse of any thing into the heart? And this *Hippocrates* in his booke *de corde* plainly auoucheth, whose words because they are sweeter then Nectar and brighter then the midday Sun we will willingly transcribe. *At the mouth or ingate of the Arteries, there are three round Membranes disposed, in their top like a halfe circle, and they that prie into these secrets of Nature, do much wonder how these orifices and ends of the great Arteries do close themselves: for if the heart be taken out, and one of these Membranes be lift up & another conched down, neither water nor winde can passe into the heart: and these Membranes are more exactly disposed in the mouths of the left ventricle, and that for very good reason.* Thus farre *Hippocrates*. From whence I gather, if nothing can passe through the Artery into the heart, how shall the blood attenuated in the Arteries of the Spleene passe thereinto, as *Florus* conceiteth? But I know what the answer will be, that those Membranes are not ordained altogether to hinder the passage too and fro; but that nothing should passe together or at once after a tumultuous manner. But this is idle to decline the force of the argument, for the blood that is brought into the heart for the generation of vitall spirits, must both be abundant, and at once abundantly exhibited vnto it; which these semicircular Membranes will not admit. But concerning this question, we shall haue occasion to dispute hereafter when we entreate of the preparation of the vitall spirit, for this time therefore thus much shall suffice.

Obiection answered.
4. vses of the
Arteries of the
Spleene.

Notwithstanding, whereas he objecteth that the large and manifold arteries which are in the Spleen were not ordained in vaine but for a further elaboration of blood, I answer that the vse of the Arteries of the Spleene is fourefold. The first, that by their pulsation they might purge and attenuate the foeculent and drossie blood; the second to solicit or call this blood out of the Veines into the substance of the Spleen; the third to ventilate or breathe the naturall heate of the Spleene defiled and almost extinguished by so impure a commixtion, least it should faint and decay; and finally, to impart vnto the Spleen the vitall faculty. And so wee see how these notable Arteries are not without especiall Reasons ordayned by Nature.

Answer to the
argument of
the Symptomes.
Perfect crea-
tures may liue
without their
Spleenes.

As for the Symptomes which follow Splenetick Patients, they happen from the impurity of the blood, not yet cleansed from this foeculent excrement, and are rather effects of a fault in sanguification then of the store house of the spirits. Moreover, if the Spleen had beene ordained for the preparation of the vital spirit, it should haue been found in all perfect creatures, because that spirit is of absolute necessity for the maintenance of life. Yet *Laurentius* saith, that a few yeeres before he wrote his Anatomy, hee cut vppe at *Paris* in *France* the body of a young man corpulent and full of flesh, wherein he found no spleen at all: the splenetick branch was there and that very large, ending into a small glandulous or kernelly body, and

A story out of
Laurentius.

and the two *hemorrhoidall* veines which purged the feculency of the blood. *Pliny* in the 11. Booke of his *Naturall* history, writeth that the Spleene is a great hinderance to good footmanhippe or swift running, and therefore some doe vse to feare it, yea and they say that a creature may liue though it bee taken out of the side. Againe those creatures which haue lesse of this droffie slime haue no spleenes, and yet it is not to be denied but they ingender vitall spirits. Hereof *Aristotle* is a witnesse, in the 15. chapter of his 2. Booke *de historia Animalium*, where he saith that the spleene is in al creatures which haue blood, but in many of those which lay egges it is so small that it cannot almost be perceiued, as appeareth in Pigeons, Kites, Hawkes, and Owles.

Pliny.

Aristotle.
Creatures that
lay egges haue
small spleenes.

These things being so, let vs now lay downe our opinion concerning the vse of the spleen. We will therefore with *Galen*, that the spleene is ordayned for the expurgation of feculent blood; and therefore Nature hath placed it opposite to the liuer, that the thick and muddy part of the iuyce being drunk vp and exhausted, the blood might be made pure. This melancholy iuyce by a wonderful prouidence and vnknowne familiarity the spleen inuiceth vnto it selfe, yet not pure and vnmingled as the bladder draweth choler, but allayed with much benigne iuyce and laudable blood; because as we sayed before, where the draught is made through large orificies, there the iuyce is neuer sincere, but mixed with some other humor.

Concerning
the vse of the
spleene, agree-
ing with the
truth.

This blood thus drawne and brought by the *Splenicke branch*, the abundance of Arteries doe attenuate, mitigate, & concoct, making it like vnto the Spleen, which is nourished with the purer part thereof. This *Galen* witnesseth where he saith, *That the Spleen draweth thicker blood then the Liuer, but is nourished with thinner, and the impure part sometime belcheth back into the bottome of the Stomacke, sometime falleth into the Hemorrhoidall veines*; and this is the true and vniforme opinion of *Galen* and the most Physitians concerning the vse of the Spleene, which it shall not be amisse to proue also by some arguments. It is most certaine that in the Liuer there are ingendred with the blood three kinde of excrements, one thinne and more ayry which swimmeth aloft and is called *Choler*; another thicker and more earthly answering to the lees of wine, the third watery and whaey. The Choler because his acrimony is more prouoking, is first of all sent aside; the melancholly iuyce as being more myrry and impure, needes the more forcible expurgation; for this expurgation, it was necessary there should be some receptacle and that not far distant from the place of concoction.

Galen.

Confirmed by
reasons.
The first.

This receptacle is neither the stomach nor the guts, nor the kidneies, nor the branches of the hollow veine: it remaineth therefore that it must be the spleene, which receiuerh a notable splenicke branch from the trunk of the gate veine and the lower parts of the Liuer. An argument hereof is the couler of the spleene, which is almost in all creatures blacke or brownish, as also sower to taste: now such as the couler is of any part, such is the humor that hath dominion therein.

From the cou-
lor and taste.

Moreover that the Spleene is ordained for the drawing and purging of the lees of the blood, these things doe sufficiently witnesse: First, because it is most subiect to obstructions and schirrous tumors, not by reason of his substance, for it is rare and fungous like a fast sponge or a smooth pumy-stone, not by reason of his vessels which are very large: wherefore by reason of the humor contained therein, which if it were thin would neither beget obstructions nor such schirrous hardneses. This *Galen* teacheth in the 13. booke of his Method. *The substance*, saith he, *of the Liuer is very liable to the schirrhous, as Naturally containing some myrry and grosse iuyce: the substance of the spleene is more rare and open then that of the Liuer, but yet is oftner afflicted with schirrhous tumors, because of a kind of aliment wherewith it is refreshed.* And againe in his 5. Booke of the *Faculties of simple medicines*. *The spleene hath ample passages.* From whence then proceed these frequent obstructions but from the grosse and feculent blood? In respect of this thicke humor, *Galen* in his 5. Booke *de sanitate tuenda* saith, *That the spleene is helped by the exercise of the upper and lower parts to attenuate it.* And in *Plutarch*, *Orchomenes the Lacedemonian* was very spleeneticke, yet he so exercised himselfe in running, that at length he obtained the prize in a Race.

2. Argument.

Why the spleen
is subiect to
obstructions
and schirrous
tumors.
Galen.

Plutarch.

Furthermore, that the spleene is the receptacle of feculent blood may thus be demonstrated: If the spleene bee obstructed, this muddy blood floweth presently backe vnto the Liuer, and infecteth that which is pure and laudable with his couler, & hence the habite of the body becommeth melancholy, and the patient ouertaken with the blacke Iaundise, euen as when the passage of gall is obstructed the choler returneth into the Liuer, whereupon the whole body becommeth yellow in a yellow Iaundise. For this cause I thinke it was that the Ancients placed the seate of laughter in the spleene, for it is a knowne Disticke.

3. Argument.

The cause of
the blacke and
yellow iaun-
dise.

Cor sapit, ac pulmo loquitur, fel continet iras,

Splen ridere facit, cogit amare iecur.

The seate of wisdom is the Heart, the Lungs our Tongues doe moue;

The Gall our Rage, the Spleene our Mirth, the Liuer holds our Loue.

Plato.

And the Diuine *Plato* alluding hereto, writeth that the Spleene is placed next vnto the Liuer to keepe it alwayes pure and bright and shining like a mirrour, fitte to returne the mages of those things that light vpon it.

Objection.

But there are many things objected against the trueth of this opinion, which is very reasonable we should answer and dissolue. If the Spleen had bene ordained for the drawing and purging of the melancholy iuyce, then Nature would haue provided some passages to leade it from the Liuer; there should haue bene also some cavity to receiue it, and some wayes by which it might be thrust forth. So there are certaine passages of the gal dispersed through the whole body of the Liuer, and hollow like arteries which leade the choler from the Liuer: there is also a notable cavity in the bladder receiuing it, and wayes by which it is thrust downe into the *duodenum*. In like manner, Nature for the vrine provided the emulgent vessels to leade it from the hollow veine; the membranous cavities of the Kidneies to receiue it, and the vreters and bladder to expel and auoyde it; but for the melancholy iuyce there are no proper and peculiar passages to leade it to the Spleene, no cavity or hollownes in the Spleene to receiue and containe it, nor any wayes whereby it might be auoyded; and therefore the Spleene is not ordained for the drawing and expurgation of this humor. That there is no pipe, passage, or vessel appointed for the transportation of these lees of the blood may be proued thus. Nature is so prouident that as soon as sanguification is perfected, she prouideth that the noysome and *heretogeny* parts should be purged and separated from the laudable blood, that it might not be adulterated with theit contagion. But if the melancholy iuyce should passe away by the splenicke branch, this counsell and law of Nature should be vtterly ouerthrowne, because it must needs passe through the trunke of the gate-vein, & defile with his slimy muddines all the branches that belong to the stomack, the kall, and the neighbor parts. Neither can the Spleene be a fit receptacle for this melancholy iuyce, because in it there are no hollow veines, whereas this thicke excrement would occupy a greater place then a thinne. Finally, there are no passages by which these lees might be thrust forth, for it is not returned into the *hemorrhoidal* veins, nor into the bottome of the stomack; because if it were thrust into the *hemorrhoidal* veins, then all men should be troubled with hemorrhoids, because all men haue this foeculent blood: adde hereto, that the blood that floweth by these veines is thinne and purple, not blacke and thicke. Againe, if the Spleene should belch out the reliques of this foeculency into the bottome of the stomacke, it should at length be auoyded either by vomit or by siege, and so we should continually haue sowre vomits or eructations, and blacke stooles.

Answer to the former arguments.

These and such like are the arguments by which the aduersaries of *Galens* opinion doe contend against him. But their blunt weapons will not fasten in the flesh, *Nullus sequitur de vulnere sanguis*. For we answer, that the splenicke branche is a fit vessell for the conueyance of this melancholy iuyce, from which although almost all the veines of the stomacke and the Kall doe arise: yet those parts doe not draw into them this impure blood, but onely the Spleene which by a kinde of familiarity challengeth it as his proper guest. So the Kidneies alone do sucke through their ample vessels the whay, not pure but mingled with the blood.

Galens objection.

His owne answer.

Why there is no notable cavity in the Spleene.

As for a cavity, we doe not thinke it necessary in the spleene, because there are an infinite number of beds and webs of veines and arteries therein, in which the slime and muddy blood is boyled and attenuated: so in the Liuer there are many of these webbes and yet no cavity, as also in the breasts and the testicles. *Galen* in the 4. book of the *use of Parts*, and the 6. Chapter, asketh the question why there bee two kidneies and but one bladder, and one spleene? he answereth himselfe, because the ferous or whacy humor is in greatest quantity, the choler lesse, and the melancholy least of all. The whacy thinnest, the melancholy Lees thickest, and the choler betwixt both. And therefore for a little and thicke humor which was hard to be moued, a great and rare organ was most fit; but it needed not to be hollow, because the melancholy iuyce was not sodainly to be remooued, but by degrees and length of time to be changed and altered. Now, if there be any reliques of this melancholy blood, who will deny that it is auoyded by the Hemorrhoidal veins at the seige, or by the venal vessell into the bottome of the stomacke. Neither doth it hence follow, that the stooles should

should bee alwayes blacke, or the vomits sowre; because a little quantity of this foeculent blood by the heate of the inward parts may bee digested and spent in a vapour, as the excrements of the bones, the gristles, and other parts. But if it abound as it hapneth in melancholy men, then the excrements of the belly, the bladder, and the hemorrhoid veines appeare blacke.

Tis true indeede, that sometimes a right thin, and purple blood passeth away by the hemorrhoides, because the Leeches sucke that which is thin, the thicker setling because of the streightnesse of the wound: or els we say, that there are two kinds of hemorrhoids, the one externall, the other internall; the internall arise from the splenick branch, and the externall from the Iliack: the first do euacuate ill disposed and foeculent blood, the other do empty the turgid and full veines, and therefore the blood that passeth from them is pure and lawdable.

Externall and
internall He-
morrhoids.

QUEST. XVI.

By what wayes the Melancholy iuyce passeth from the Spleene to the bottome of the Stomacke, and for what vse.

Almost all Physicians do agree, that a part of the Melancholy humor is discharged into the Stomacke, but by what passages and to what end, they cannot so well accord. *Auicenna* thought, that it is carried vnto the mouth of the stomacke by the Coronary veine before it enter into the Spleene. *This a strange thing* (saith he) *that the light choler should be sent downeward vnto the guts, to redeeme the stomacke from his acrimony, and the heavy and dull Melancholy should rise upward to the mouth of the Stomacke for the commodity thereof.* *Galen* seemeth to haue thought diuersly concerning this matter. In the 3. Booke of *Naturall Faculties* he writeth, that it passeth from the Spleene vnto the Kall, thence into the guts, and by them to the pylorus, and at length to the bottome of the Stomacke. In his Bookes of *the vse of Parts*, he openeth a neerer way, to wit, the *Vas breue & venosum*, that is, the short or venall vessell, reached from the vppermost branch neere the Spleene to the bottome of the Stomacke.

Auicenna opin-
on.

Galen

In his Booke of *the Dissection of Veines and Arteries*, hee affirmeth that this short vessell is not found in all creatures. For mine owne part (saith *Laurentius*) I haue alwaies obserued it neuer to be wanting. This passage therefore being so short and conspicuous, is most like to be ordained to conuey a part of the Melancholy iuyce, which is like vnto the lees of Wine, into the bottome of the Stomacke which could not bee mittigated and attenuated by the power of the Spleene. Yet I will not deny but that when this short vessell is stopped the grosse iuyce returneth into the splenicke branch, and from it sometimes into the Coronarie veine of the stomack, sometimes into the Hemorrhoidall, and sometimes into the veines of the Mesentery. But why should this Melancholy iuyce be sent back into the bottome of the stomack? the common and true opinion is, that it is done to stirre vp appetite, for it is cold and sowre; now all cold and sowre things because they astringe or binde and corrugate or contract the mouth of the stomacke, doe prouoke appetite. So *Hippocrates* in *Epidemics* saith, *That water is deuouring, and Melancholy men are great eaters.* *Auicenna* thought that this Melancholy did not onely by his astringe stirre vppe appetite, but also further retention & concoction; and of the same minde is also *Galen* in the 5. Book *de vsu partium*, *It streighteneth the Stomack, and contracteth it into it selfe, and maketh it streightly to embrace the meate, and to retaine it till it be concocted.*

Obiection.

Answer

How Quar-
tane agues are
often eased.

The stomacke
ill affected in
quartanes.

If it be obiected, that if it stirre vp the appetite, Nature should haue implanted the venall vessell into the mouth of the stomacke, which we determine to be the seate of appetite; We answer that it is not so placed by the prouidence of Nature, least continually gnawing and prouoking the mouth of the stomacke, it should induce a perpetuall and rauinous appetite. By the benefit and help of this branch, those who are diseased with a quartane Ague (who for the most part haue it very large) are much eased by vomits, whether they come of themselves, or are procured by Art both before and after the Paroxisme or fit, especially in the declination of the Disease. This same branch also is the cause why in Quartanes not onely the Spleene is affected, but also the mouth of the Stomack, yea, almost in all Diseases which proccede from Melancholy the Stomacke beareth a part of the burthen.

QUEST.

QUEST. XVII.

How those that are splenetick are purged by Vrine, and by what waies those purgations passe.

Hippocrates
calleth the
Melancholie
humor water.

And why.

Much sweate
and vrine in
Quartanes.
Melancholy
men great
spitters.

How to purge
it.

Vlcera sceler-
tyrica, how
cured.

Hippocrates
story of Bion.

Anicen.

Experience.

Black waters:
Hippocrates.

How Critical
waters becom
black.

The passages.

That all splenetick and Melancholy persons do abound with Vrine, as well the authority of Hippocrates, as also reason and experience doe perswade. Hippocrates calleth the Melancholy iuyce *Aquā*, that is, Water, in his fourth Booke de Morbis, where he saith, Both the Man and the Woman haue foure kinde of moystures, Flegme, blood, Choler, and Water. And in his Booke de genitura, there are foure kinde of moystures, Blood, Choler, Water, and Flegme. By Water all Interpreters vnderstand the Melancholy humour, because that of all humors hath most Whay or Vrine in it, for it is cold: wherefore when that aboundeth, the naturall heate of the Spleene, the Stomacke, the Liuer, and neighbour parts is wasted and dissolued, from whence proceedeth a great encrease of crudities and waters. Adde hereto that it heloued this crasse humor to haue much whay mingled with it, to be a weftage or vehicle thereunto. Common and daily experience addeth strength to this opinion, for in quartane Agues there is much sweate and much water made, and Melancholy men are all of them *spitatores maximi* great Spitters: therefore Galen out of Dioscorides in his 3. Booke de locis affectis, reckoneth abundance of spittle to be the principall amongst *Hypochondriacall* signes.

This therefore is to be resolued of, that splenetick persons doe abound with serous humour. Furthermore that it is purged by Vrine, Hippocrates, Galen, Anicen, Paulus, and Rhafis doe teach, and we finde it true in our dayly practise. Hippocrates in his Booke de internis affectibus, writeth that the Medicines which are prescribed to splenetick persons, ought to purge by the Bladder; and in his Booke de externis affectibus, hee willeth that those cholerick Patients who haue great and turgid Spleenes, and thereupon are ill coloured or troubled with malignant vlcers, should haue their Vrine prouoked. The moderne Practitioners doe cure the vlcers called *sceleratica*, which are contracted or gotten by the fault of the Spleene, by diureticall and diaphoreticall medicines, that is, by such as prouoke vrine and sweate.

Hippocrates relateth an elegant History of Bion, in the second Booke of his Epidemia, and the Second Section. Bion (saith he) did make much water without any residence, and the blood yssued out of his left nostrill; for his Spleene was puffed up and hard. Galen in his second Booke ad Glanconem, cures Quartane Agues with Diureticall Medicines, such as prouoke Vrine. The guts (saith hee) are to bee purged by the seige, but the Spleene and the Kidneyes by the Vrine.

The same Galen in his Commentaries in sextum Epidem: writeth that Blacke Vrines are signes of a colliquated or resolued Spleen. Anicen Fen. 15. tertij. When splenetick persons (saith he) do vse much exercise, the Melancholy humor is deriued to the passage of the vrine, & the vrines become blacke. And we our selues haue obserued many splenetick persons to haue recovered their health by a liberall and free profusion or euacuation of Blacke Vrines. But wee must obserue that such Vrines are not blacke in their proper liquor, nor in their Generation (because those according to Hippocrates in his Prognosticks, Prorrhethicks and Aphorismes are all mortall, for that they bewray either an extraordinary heate torrifying all things as it were into a blacke Cinder, or else an extinction of naturall heate and a *Morticinium*, that is, an utter deadnesse) but they are blacke through a permixtion of a blacke humor, which the Spleene hath purged and put downe into the Kidneyes.

Now by what passages or wayes this serous and Melancholy iuyce is purged from the Spleen vnto the Kidneyes it is not so easily knowne. There are two kinde of vessels dispersed through the substance of the Spleene: Veines arising from the splenetick branch, and many Arteries.

Betweene the splenetick branch, and the emulgent Veines, there is no communion vnlesse it be as farre off; for the splenetick branch ariseth out of the trunk of the port or gate-veine, but the emulgent from the descending trunk of the *cava* or hollow veine: now betweene the hollow and the gate-veines wee know there is no communion vnlesse it bee by the

the

the mingling of their mouths in the substance of the liuer; for some of the new writers haue obserued many such inoculations betwixt them in that place. Wherefore if the expurgation or auoydance of this melancholy humor be made by the veins, it must be returned from the spleene to the gate, from the gate to the hollow, and from the hollow to the emulgent veines, and so vnto the Kidneyes, which were a long and tedious course.

Our opinion therefore is, that this expurgation is rather made by the Arteries then by the veines, because the humor contained in the spleen, may by a neerer and more open passage be deriued from it vnto the emulgent Artery. So the *Empyici, pleuratici & peripneumonici*, that is, such as haue suppurations in their chest, are afflicted with the pleuresie or inflammation of the lungs, haue the matter or quitture euacuated not through the veins but through the Arteries: and beside, our eyes teach vs that there is more serous and whaey humor contained in the Arteries then in the Veines.

And for this reason I thinke the emulgent Arteries were made so large and so ample, not so much to leade and bring down the vitall spirit (for if they had been but small, they would haue serued that turne) as to purge the whay contained in the arteries by the Kidneyes: for so *Galen* teacheth vs in his 5. Booke *de usu partium*, and in his Booke against *Erasistratus*. And so much concerning the vse of the Spleene, and the way of the melancholy vnto the Stomacke and the Kidneyes. Now followeth that we should treat of the Kidneyes themselves.

QUEST. XVIII.

Of the vse of the Kidneyes, and the matter of the vrine.

Erasistratus and *Asclepiades* as *Galen* witnesseth in his Booke *de Naturalibus facultatibus*, ascribed no vse at all almost to the Kidneyes. *Aristotle* in his Booke *de partibus Animalium*, supposeth that they were at the first intention ordained to hold or containe and establishe the veines, and that in the second place or by the bye, Nature abused them for the excretion of a superfluous humor. We with *Hippocrates*, *Diocles* and *Galen* 1. *de Naturalibus facultatibus*, 5. *de usu partium*, and in his Booke *de locis affectis*, doe thinke that they were framed for the expurgation or cleansing of the Veinall and Artericall Blood. For whereas in the Liuer after concoction, there ariseth a threefold excrement; one *billious* or cholericke, another *feculent* or melancholy, and the third *serous* or whaey; the two former as soone as Concoction is celebrated are purged away, but the third remaineth to conduct the thicke and sluggish blood, that it might more easily and freely passe into the narrow and threddy veines. It was therefore meet that at length hauing performed this his office, it should also be separated and purged as an vnprofitable superfluity, and discharged into his proper receptacles. These receptacles are the Kidneyes, which is euident enough because their substance is hollowed into diuers caues or dennes, and perforated or pierced through with many drayning pipes; as also because of the continuity they haue with the great Bladder of Vrine by the mediation of the Vreters.

But how this expurgation is made, whether by the traction of the Kidneyes, or by the expulsive power of the Veins, or by the proper motion of the whay, or after what other manner, it is not yet fully agreed vpon.

Erasistratus conceived that this expurgation came to passe by a necessary succession of one part of that which was euacuated to another, that is to say for auoyding of vacuity. But we wil not so much as vouchsafe any answer to his opinion. *Hippocrates*, *Diocles*, *Praxagoras* and *Galen*, 1, 2, and 3. *de faculte natural.* 4. *de usu partium*, and 6. *de locis affectis*, doe all conclude that the Kidneyes by a kinde of ingent propriety, doe draw the whay vnto themselves, not pure but mingled with blood. The blood is there referued and applyed to the substance of the Kidneyes like a dew after it is assimilated and turned into their substance; but the whay being vnprofitable for nourishment, is first of all separated, next because of his thinnesse is deriued through certaine fleshy caruncles strutting out like the nipples of breasts, into very many pipes or fistules, and from these into a membranous hollownes, as it were into a Cisterne, and out of it through the Vreters into the Bladder.

Some of the new writers haue thought this expurgation of the whay is not made by the Traction of the Kidneyes, but onely by the expulsion of the Veines: because nothing draweth,

weth, *proprie ipsum trahere*, that is, for the drawing it selfe, but that it may enioy that which it draweth; but we know that the kidneies are not nourished with the whay neither with serous blood, because their substance is dense, solid, and compact, and the serous blood very thinne; and therefore the vrine is deriued from the veines, by the power and force of Nature, which is either burnd with abouidance thereof, or prouoked by his saltnes and acrimony. There want not also some which defend the quite contrary, that there is no vse of expulsion in this expurgation, because then there should be a compression of the veines and arteries, the vppermost being contracted and the lowermost relaxed, & by that meanes not only the whay but also the whole masse of blood should be driuen downe into the kidneis.

vrine.

Answers.

Againe, the scituation of the Kidneyes seemeth to contradict this conceit of expulsion; for if that had beene their end, then their fittest position had beene directly vnder the hol- low veine and the great artery, and not at the sides. Adde hereto, that this expulsion of the whay should not onely haue beene into the emulgent, but also into all the crurall and Iliac branches: yea rather into the lower and neather vessels. And therefore this serous humor, say they, is neither drawne by the kidneies nor by them driuen, but of it owne accord pas- seth vnto them, which passage some haue thought to be by accident, as *Erasistratus* of whose opinion we made mention euen now: others by it selfe, that is, by a proper faculty as *A- uerrhoes* that acute Arabian, who thought that the Aliment was not drawne by the parts, but by an ingenite power and vertue of it owne did passe vnto them. For as in concoction the Aliment getteth a new forme, so it also getteth a new faculty, whereby it is moued to this or that part of the body: so the Elements by their proper formes are moued each to their proper place. But neither *Erasistratus* nor *Auerrhoes* can be approoued, because they both take away the faculties of the soule, especially the Tractiue which ministreth vn- to nutrition.

We as our manner is, to reconcile the different opinions of these great learned men do say, That the vrine is partly drawne and partly expelled; but the force of the Tractiue is greater then that of the Expulsion. And yet we affirme also, that some is onely expelled not drawn at all; and some againe neither drawne by the kidneies nor expelled by Nature, but onely passeth on by a beaten way, which of long time it hath beene vsed vnto. The Vrine when it is naturall and no way tainted, and is onely the whay of the blood, is partly drawne by the Kidneyes, partly driuen by the expulsive power of the veines, especially if all the frame of our naturall and legitimate health doe stand, as they say, in right tune: but yet in this ex- purgation the attractiue vertue of the Kidneyes is very great, and the expulsive of the veins very light and weake.

For why should the whay rather fall into the kidneies then into any other part, vnlesse there were a peculiar Tractiue in the kidneies? In *Perirrhoea* or the Criticall fluxe or the V- rine, it is onely driuen and not drawne by the kidneies: but in a *Colliquation* it is neither dri- uen into the kidneies, because the expulsive faculty is too weake, neither drawne by the Kidneies, but as the Poet saith, of the winde, *Qua data porta ruit.*

Where may it be made,
It followeth glad.

These things that they may be made more manifest and apparent, it shall not be amisse to bring them againe to the hammer and the anuile. The matter of the Vrine is very mani- fold: first all our drinke, sometimes raw and crude and of the same couler it was taken in, sometimes a little altered: secondly, the serous liquor of those humors which are contained in the veins: thirdly all kinde of humors, yea and bodies that are melted, as flesh and fat. This threefold matter *Hippocrates* comprehended in the first section of the 6. Book *Epidemi- on*, where he saith, *The Vrine is of the same couler with the meate and drinke, as well when it is as it should be, as when it is a colliquation or melting of the moysture.* A wonderful, short, plaine, and yet absolute sentence, so as I thinke it vnpossible to expresse more in fewer words.

Whereas he sayeth that the Vrine is of the same couler with the meate and drinke, it sheweth the first matter of the Vrine, to wit, the drinke which some haue thought to bee the sole and onely matter, being perswaded thereto by these reasons. First, because those creatures which doe seldome or neuer drinke haue no bladders, but those that drinke much, do also auoyde much vrine. Secondly, because according to the rule of Physitians, the quan- tity of the vrine should be answerable to the drinke. Thirdly, because in the suppression of vrine, we interdict our Patients drinke, that the quantity of the vrine should not bee en- creased. These things truly proue that the greatest part of the matter of the vrine is sup- plied

plied by the drinke and liquid meates; but they do not conclude necessarily that those are the only and alone matter of it. For the Infant auoydeth water in the mothers womb by the vessell called *Frachos*, yet it drinketh not; and againe in winter wee make more water by much then in summer, & yet we drink lesse. And *Galen* in his first booke *de locis affectis*, telleth a tale of a young man who auoided as much water as came to 4. *Hemina*, that is, 36. ounces, about a quart, and yet in 3. dayes he had taken neither meate nor drinke.

The second particle is (*when it is as it should be*) whereby *Hippocrates* sheweth the second matter of the vrine which is the true and legitimate matter thereof, and that is the whey of the foure humors which are contained in the veines, and therefore *Galen* defineth *per* the vrine, to be *οἷον τῶν κατὰ τὰς φλέβας χυμῶν*, that is, *The whey of the humor in the veines*. As for *Lycus* the *Macedonian*, he is not to be harkened vnto, who affirmed, that the whey was only the excrement of the Kidneyes. For how was it possible that so small bodies as the Kidneyes are, should beget so greata quantity of wheacy humor? And if be obiected, that *Galen* in one place saide, that the vrine is the proper excrement of the Kidneyes and the bladder: Wee will answer, that it is therefore called proper, not because it is engendred in the Kidneyes, but because it is drawne and separated by them alone.

The second matter of the vrine, the whey of the foure humors.

Obiection out of *Galen*.

Answer.

The last particle in *Hippocrates* expresseth the third matter of the vrine, to wit, *All humors and bodies which are melted or colliquated*: the humors are al of them purged by the vrine very often, as in criticall euacuations by the bladder, in a purulent *perirrhæa*, & such as is accompanied with a Strangury, or the Symptomes thereof. There remaineth vpon record concerning this matter a solemne edict of *Hippocrates* in the second section of his first booke *Epidemion*, where he saith, *Many doe auoid vrines bilious, watery, purulent, fretting, and stranguous or issuing by drops*, because as *Galen* interpreteth it, *The whole body did put downe by the vrines great aboundance and varieties of euill humors*. But of this expurgation we shall haue occasion to speake in another place.

The third matter of the vrine are the humors of the body.

Hippocrates. *Galen*.

Neither are the humors only, but also such bodies as are colliquated & melted the matter of the vrine, such as are fat and flesh: and hence come fatty and oyley waters, when a consuming Ague melteth the body, which are called signes of colliquation, whereof *Hippocrates* speaketh in his prognostiquis on this manner, *That vrine is it which is oyley or fat when it is made*: now by Oyleinesse he doth not vnderstand either the colour or consistence of Oyle, but melted or colliquated greace swimming in the surface of the water. Concerning this threefold matter of the vrine, *Ludouicus Duretus* a great learned man of France, hath written at large in his elegant and learned Commentaries in *Coacaspranotiones* of *Hippocrates*.

Hippocrates.

What an oyley Vrine is.

Ludouicus Duretus.

These things therefore being so, and that matter of the Vrine so manifold, we conclude that all vrine is not drawn by the kidneyes, but that only which is naturally disposed, to wit, the whey of the foure humors contained in the veines. Notwithstanding the Kidneyes are not therewithall nourished, for all traction is not for nourishment: the Load-stone draweth iron and Amber chaffe, yet are they not nourished by them. But the vrine (which hath for his matter crude humors or any other) which is freely and abundantly poured forth on the Criticall dayes, we thinke is onely driven and not drawne. But if the vrine do flow from the colliquation or Liquefaction, either of the humors, or of some more substantiall part, it is then neither drawne by the Kidneyes, because it is not *According to Nature*, neyther is it expelled by the power of the veines, because there is a generall exolution or weakenesse of the spirits: but it passeth of his owne accord through most patent and ample vessels to the Kidneyes, because those places are most accustomed to that euacuation. And this I take to be the sum and substance of this Controuerfie.

The Conclusion.

QUEST. XIX.

That the reasons of diuers Symptomes which follow such as are afflicted with the Stone, are to be required from Anatomy.

IT belongeth neyther to this place nor time to dispute about the causes and generation of the stone, we rather sticke to those things that concerne Anatomy. But because *Nephriticall* patients, that is such as are troubled about their Kidneyes, especially with the ston, haue diuers accidents, whereof there can no reason be giuen but onely from Anatomy, I haue not thought it amisse briefly to lay them open with their seuerall causes

causes for the satisfaction of such as are not so well exercised in our Art, who notwithstanding may desire satisfaction in this point.

Paine wander-
ing & fixed.

The *Nephritical* paine doth oftentimes imitate that of the collick, so that by the similitude not only the ignorant but such as are right skilfull are often deceiued. Notwithstanding they are distinguished by their particular Symptomes, by those things which are auoided, and those that are applied. The most greuous Symptom of all the rest is paine, which in the collick is wandering, but fixed in the Stone. The Collick paine ascendeth like as the collicke gut ascendeth, from the bottome of the belly to the stomack, and so runneth vnder the bottome thereof; that of the Stone descendeth, because of the continuity of the vreters, especially if the stone begin to mooue. The Collick paine possesseth all the lower belly, the Nephritick may be covered with ones hand; the collick greueth the region of the *Hypogastrium* and of the nauell, the stone lyeth forer in the Loines backward.

An obseruation
out of the
Arabians.

Some haue obserued out of the *Arabians* that the Collick paine is lesse when the stomack is empty, but the other then is exasperated. And againe, when the stomack is filled the collicke encreaseth, which must be thus vnderstood. That the Collick paine euer abated when the stomacke and guttes are empty, but the Nephritick not alwaies; because the stone lyes goading in the same place. Yet sometimes after meate the Nephritick paine is abated, because the stone being fixed in the kidneyes the waight of it preffeth downward, and thence the paine proceedeth; but when such men haue eaten, the guttes which support and suspend the Kidnies do swell, and so the paine is mittigated. There are also some nephriticall paines which are exasperated vpon the eating of meate, as when the kidneyes are inflamed the distention of the stomack and guts do encrease it. Againe, the paine of the Kidneyes beginnes dully, that of the collick is alwayes a cutting and a sharpe paine. If it be objected, that *Hippocrates* in his Book *de internis affectibus* affirmeth, that the paine of the kidneyes is sharpe;

Obiectiō out
of *Hippocrates*.
Answer
out of *Galen*.

we may answer out of *Galen* that there is a double kinde of paine, the first is occasioned by the Tartnes of the humor, or sharpnesse and asperitie of that which is contained, (imagine it to be grauell) and both these make the paine somewhat acute or stinging; the other is by reason of the waight when the Kidneyes are oppressed with abundance. The paine which proceedeth from Tartnes and acrimony, is both in the generation, and also in the expulsion of that which offendeth: that which is from the weight taketh vp all the time betwixt the generation and the expulsion. Or thus, the paine of the Stone is dull whilst it resteth in the Kidney, and acute when it mooueth into or toward the Vreter. There are also other Nephriticall Symptomes; for the thigh that is on the same side wherein the stone lyes, is as it were benumbed or asleepe, which is not so in the Collicke paine, wherein the vomitings, loathings of meate, and distastfull belchings are more frequent and greuous, and so much of the Symptomes.

Another
meanes to di-
stinguish these
paines.

Secondly, these paines are distinguished by those things that are auoided; for in the collicke the excrements are more obstinately retained, that not so much as a little winde can finde passage, but in the nephritical paine the vrine is rather suppressed. In the collick paine the vrines are thinner in the beginning, and afterward become more thick; and if any winde or flegme be auoyded, the paine is either mitigated, or else ceaseth: but the nephriticall is not appeased till the stone be auoided. Finally, those things that are taken inwardly or applied outwardly, do distinguish these paines.

How the stone
of the Kidnies
is distinguish-
ed from that
of the bladder.

Now the stone of the kidneyes is knowne or discerned from that of the bladder by the propriety of the paine, by the situation, and by the dulnesse. The bladder is placed in the *Hypogastrium*, the kidneyes in the Loynes; the generation of the stone in the bladder is without any sense of paine, because of the largenesse and capacity of the bladder: in the kidneyes it is engendred with paine, because of the narrownesse and streightnesse of the kidney. In the stone of the bladder, the vrine is euermore suppressed, not so in the stone of the kidneyes because there are two of them, that if one be ill affected, the other might serue the turne. Againe, the Strangury and the *Tenesmus*, that is, the pissing by drops and a vaine desire of going to the ground, do alwayes accompany the stone of the bladder because of the vicinity or neighborhood of the right gut, which is not so in the stones of the kidneyes.

The grauell of
the kidneyes red,
and that of the
bladder white.

Some there are which make a difference betweene them in regarde of the grauell, because that of the Kidneyes is redder, that of the bladder whiter: the stone also of the kidneyes is softer, that of the Bladder harder. But this is not alwayes true, for the hardnesse and heate of grauell are to be referred to the power or efficacy of the efficient, and the condition of the matter. And so according to the degree of heate the grauell is eyther white

or yellow or blacke, and according to the condition of the humour; when they are made of phlegme they are ash-coloured, and red when they are made of blood. But I may seeme here to haue grazed beyond my teather, I therefore returne.

There are two *symptomes* which follow the *Nephretical* paine, a stupor or sleepines in the Thigh on the affected side and a Vomiting. The cause of this stupor, the learned *Langius* in his Epistles, and *Iacotius* in his Commentaries in *Coacas praxiones* of *Hippocrates*, doe referre to the repletion of the veines. The large vessels say they of the hollow veine and the great arterie as they descend downward, doe lye vpon the ridge of the back, and from them there be notable branches scattered vnto the Kidneyes and the thighes, in whose repletion (which happeneth when the Kidneyes, the Vreters, or the emulgent vessels are obstructed) the nerues & the muscles are straightned, and thence that stupor or sleepinesse proceedeth. But this reason seemeth not to me very *Anatomical*; for the stone in the kidneyes doth not cause the veines so to strut that they should presse the muscles, because that many which are wasted with a consumption of the Lungs or some other part whose veins are exhausted, doe notwithstanding in fits of the stone feele this dulnesse or stupidity in their thighes or legges. Adde hereto, that those that are *plethorick*, whose veines are turgid to the outward appearance, haue yet no such stupidity in the legges or armes. Wee must therefore finde out some other cause of this sleepinesse, and I thinke that it is double; the first is the compression of the muscle called *Ischi*, vpon which both the kidneyes do rest, which also all Anatomists doe obserue to bee inserted into the inner part of the thigh, and appointed to bend the same. The other reason is the compression of the nerue which is diuersified into all the muscles of the thigh; & this compression is made by the hardnesse and waight of the stone, for while the stone is small and but a growing, this sleepines hapneth not.

Now the reason why in the fit of the stone there is so great a subuersion or turning of the stomacke, that the Patient loatheth all meates, and presently casteth vp whatsoever hee receiueh, is the sympathy or consent betweene the stomacke and the kidneyes; and the cause of this sympathy which is simple, is not to be referred to their vicinitie or neighbourhood, because there is a good distance betweene them, not vnto the similitude or likeness of their kindes or substances, for the stomacke is membranous and the kidneyes fleshy; not vnto the society or entercouse of their operations, for they are not occupied about one and the same labor; it is therefore to be referred to the communion and continuation of their vessels and membranes. For there are certaine small nerues which are carried from the stomacke nerue to the kidney; and the outward coate inuesting the kidneyes which is commonly called *fascia* or the *swathe*, hath his original from the *Peritoneum* or rim of the belly, which all men know is continued with the bottome of the stomacke.

The cause of the stupor of the thigh in the paine of the stone, out of *Langius* & *Iacotius*.

Confuted:

A double cause of the stupidity as is signified.

Why the stomacke is subuerted in the fits of the stone.

QUEST. XX.

Whether the Bladder doe drawe the vrine.

Concerning the Tractiue, Retentiue, and Expulsiue faculties of the Bladder, in respect or reference to the vrine, there are some small difficulties which had neede to be made plaine. And first there may bee question made of a tractiue faculty, for *Galen* sometimes alloweth, sometime denyeth it. In the 3. Booke de *natural. facult.* and the 5. de *usu part.* he writeth that both the bladders of the gal & of the vrine haue a proper power to draw their own excrement. And this the structure or frame of the bladder doth also conuince, for it appeareth to be wouen of three sorts of fibres, right, oblique & transuerse. And in the 7. chap. of the 5. booke de *usu part.* The bladder saith *Galen*, as well that which receiueth the vrine as that which receiueth the *Choler*, because both of them doe draw their proper excrements pure and segregated from the rest, do both of them by due right make claime vnto other vessels which should conuay nourishment vnto them. *Aristotle* in the 15. Chapter of the third Booke de *histor. Animal.* sayeth, That after death no humor falleth into the bladder, but whilst men are aliue not onely humour, but also dry recrements doe passe downe, of which stones are ingendred. Now if the whay did only descend & were not drawne, why should it not descend also in dead bodies? *Galen* in the 6. Booke de *locis affectis*, seemeth to be of a contrary opinion. For searching into the nature of the disease called *Diabetes*, that is, an exceeding fluxe of vrine, and the causes thereof, he affirmeth, that the bladder doth not draw the vrine vnto it selfe. But I vnderstand *Galen* that where he sayth in the *Diabetes*, The bladder draweth no whay vnto it selfe, his meaning is, that the cause of the *Diabetes* is not to be referred to the Tractiue power of the

Whether the bladder haue any attraiue faculty. *Galen*.

Galen.

Aristotle.

Galen.

The cause of Diabetes. *Galen* expounded.

the bladder, neither that it is at any affection of the bladder, but rather a symptome of the exceeding strength of the Tradition of the Kidneyes, and of the weaknes of their retention, & therefore in that disease the bladder draweth not so great a quantity of vrine, but the hot and boyling Kidneyes draw more whay then they are able to conteyne, whence either of it owne accord it falleth through the vreters into the bladder, or is thrust downe by violence.

How the bladder is nourished.

But if all things stand in good order according to the laws of Nature, then there is no reason but to think that the vrine is drawn by the vreters and the Bladder. Neither doe I think that the bladder is nourished by that excrement, considering that from the *Hypogastricke* branch there are many smal rillets of veins and arteries disperfed through both his Coates.

QUEST. XXI.

Of the Retention and Excretion of the Vrine, whether it be accomplished by a Naturall or by an Animal faculty.

Retention and excretion are natural actions.

THE proper vse of the Bladder is to retayne the Vrine to a certaine time, & afterward to auoyde it; but by what power it doth this, Animal or Naturall, there lyes the controuersie. Some conceite that both the actions, as well the Retention as Expulsion are Naturall, because there is the same reason of both the bladders of gall and of vrine, but the bladder of gall reteineth and expelleth onely by the faculty which we call Naturall. Adde hereto that the triple kinde of fibres which are in both the bladders doe perswade vs that there is a threefold Naturall action in them and not an Animal. On the contrary, it may bee demonstrated that both these actions are Animall on this manner. The Retention is made by Animall instruments, and therefore the action is Animall, this Animall instrument is a muscle. Now we know that the necke of the bladder is compassed about with a *sphincter* muscle, who playes the Porter and stoppeth the gate least the Vrine should passe away without our good pleasure.

That they are animal.

Galen.

What our resolution is.

That the Expulsion is Animal is witnessed as by other arguments, so by this, that according to our arbitrary wil it is either slower or quicker, weaker or stronger, as also because it is not acomplished without the help of the muscles of the *abdomen*. *Galen* in his first Book *de locis affectis*, and 6. Chapter, stinteth this strife, and sayth that the action is mixt: the Retention, Animal, and voluntarie, as being performed by the helpe of a muscle, the Excretion Natural which is vnderaken & performed by the expulsive faculty: For my owne part I thinke that both actions as well the Retention as the Expulsion, are partly naturall & partly Animall, but the Retention more Animall, and the Expulsion more Naturall. The Vrine is retained in the bottom of the Bladder by the help of the oblique fibres; now that Retention is natural: but beside it is retayned also at our pleasure by the helpe of the *sphincter* muscle, and this action is meerely Animall. The vrine is Expelled by the ingenite power of the Bladder, whereby it is prouoked to auoyde that which is noysome or grieuous vnto it, and this Excretion is altogether Naturall. Again, the Vrine is Expelled at our pleasures (and that action is Animal) by the helpe of the muscles of the *Abdomen* pressing the *Hypogastrium* or water course; and some thinke that those small muscles of the *Abdomen* called *Pyramidales* or *succenturiati*, that is, spirie or assistant muscles were ordained by Nature to further the excretion of this humour, and therefore both these actions are mixed.

The vrine.

Obiection. Answered out of Galen.

Some will obiection that excretion can be no way naturall, because all naturall actions being perpetuall and indefinent the vrine should bee continually auoyded. *Galen* answereth that all vrine is not the obiection of the expulsive faculty, but that onely which either fretteth or stretcheth, that is, which is offenseue either in quantity or in quality: and so much concerning the Bladder: now follow the Paps.

QUEST. XXII.

Of the action and vse of the Breasts or Paps.

The question.

LI men I thinke are resolved that there is in the Breasts an in-bred faculty of making Milke. This onely is questionable, how they which are but kernels should performe an officiall or common action, which is accomplished by alteration &

con-

concoction; seeing *Galen* denyeth vnto these glandules all action and yeeldeth vnto them onely a vse. Now that the Breasts or Paps are to be reckoned among the glandules, their substance and vse doe manifestly declare. For their substance it is rare, friable, and spongy; and for their vse *Hippocrates* in his Booke *de Glandulis* ascribeth the same vnto the Dugs which other kernelly parts performe, where he saith, *The Vses of the paps and of the Glandules before mentioned are alike, for they all sucke vp the superfluities of the whole bodie.*

For the Solution of this Question, we say there are two kindes of Glandules, for which we haue *Galen* our Author, in his second Chapter of the sixteenth Booke of the *vse of parts*. There are some Glandules which are ordained onely to establish and vnder-prop the Vessels, or to receiue superfluous humors, or to water and moysten the parts. There are others which are provided by Nature for the generation of certaine iuices or humors which are profitable for the creature. The former haue neyther Veines, nor Arteries, nor sinnewes: these latter haue very conspicuous vessels, and are of exquisite sense. The former are properly called Glandules; the latter may better be stiled Glandulous bodies. So the Testicles and the Kidneyes by *Galen* are called Glandulous bodies; and *Hippocrates* in his Booke *de Glandulis* saith, that the braine it selfe in respect of his substance is glandulous. The former are onely of some vse, the latter affoord both vse and action, amongst which wee conclude the dugs or breasts to be.

And whereas *Hippocrates* saide, that these dugs doe receiue or suck vp an excrementitious humor, we vnderstand that this is not their primary or chiefe & maine vse, but only secondary: for Nature often abuseth one and the same part to diuers vses, so the braine in manner of a *Glasse, still, or Cucurbita*, doth draw and sucke vp the expirations of the lower parts, and yet notwithstanding there is another and more diuine vse of the braine. So nature often abuseth the guts for the expurgation and vnburdening of the whole body, whereas they were originally ordained for another purpose, to wit, for distribution of the Chylus.

The Breasts therefore or Paps haue a proper action and vse. Their action is the generation of Milke, which is performed by a moderate and equall coction or boyling. Their vses are either primary or secondary: The primary vse *Galen* saith is for generation of milke, but *Aristotle* would haue them ordained for the defence of the heart, the most noble of all the bowels, and I thinke he was misled with this argument, because men had breastes, and yet did not ingender milke. Wee with *Galen* do determine, that these glandulous bodies, compassed with fat, and wouen with many thousand vessels, were first and originally ordained for Milke, and are not alike in men and women. And yet I conceiue that they were scituated in the breast rather to add strength to the noble parts contained vnder them, then for the generation of Milke. For in most creatures they make Milke not in the breasts but in other parts.

You shall therefore reconcile *Galen* and *Aristotle*, if you say, that the Dugges were created originally for the generation of Milk, and secondarily for the strengthening and defence of the heart. And againe, that the originall cause of their scituation in the breast was for the defence of the heart, and the secondary for the generation of milke.

QUEST. XXIII.

Whether Milke can be generated before conception.

It was disputed of old, and is yet a question amongst the multitude, whether Milke can be engendred in a womans breasts before she haue had the company of man and conceyued. And this doubt is occasioned by some different places in *Hippocrates* and *Aristotle*. *Hippocrates* in his first Booke *de Morbis mulierum*, inquiring after the signes of the *Mola* or Moon-calfe, reckoneth this as one of the principall, *When in the Breasts there is no Milke engendred*. And therefore the generation of Milke is according vnto *Hippocrates* a certaine signe of conception. *Aristotle* in his Bookes *de Historia Animal*, confirmeth the same, where hee saith, *That no Creature engendred Milke before the womb be filled.*

And reason seemeth to consent with their authority. For if nature do neuer endeavour any thing rashly, but all things for her proper end, what neede is there of Milke before the infant be perfected, it beeing only ordained for the nourishment thereof? Notwithstanding *Hippocrates* in his Aphorismes seemeth to be of a contrarie minde. *If a woman (saith he)*

Hippocrates.
The first ge-
neration of
milke.

Hieronimus Cardanus in his Bookes de subtilitate saith, that hee saw a man about thirtie foure yeares old, out of whose breasts so great a quantity of Milke did flow, that it was almost sufficient to nourish a childe. They that haue trauailed into the new world do report that almost all the men haue great quantity of Milke in their breasts.

If therefore men doe breede Milke, much more Virgins, and Women before they doe conceiue. For their Dugs are more rare and large, and beside they haue a greater abundance of superfluous blood. Reason also fauoureth this opinion, for where the materiall cause of Milke is present, and the strength of the efficient not wanting, what should hinder the generation thereof? Now in Virgines that bee of ripe yeares, the veines of the Chest which water the Dugges haue great abundance of blood, they haue also the strength of the glandules to alter and to boyle it: for after the fourteenth yeare, The Dugges sayth Hippocrates doe swell and the Nipples strut, and young wenches are then sayd *ruqizant*, that is *frigate*. Wherefore Milke may sometimes be bredde, in such women especially whose courses be stoppt as Hippocrates writeth. But these disagreeing places of Hippocrates it wil not bee hard to reconcile out of Hippocrates himselfe. There is a double generation of Milke according to Hippocrates, and a double nature thereof. One kinde of Milke is true and laudable, another not true nor perfectly boyled. The former is made by a great alteration and true concoction of the breasts, and that not priuate but officiall; the latter riseth of a remainder of proper nourishment of the breasts, the first is perfectly white, sweete, and moderately thick, & fitte to suckle an Infant; this other is white indeed because it beareth the colour & forme of the part from whence it floweth, but it hath neither the true nature of a nourishing Chymus or humeur, nor the sweetnes nor the power or vigour of nourishment, and therefore it deserueth the name of Milke, not by his quality or specificall forme, but onely for his colour, for it is thinne and waterish, altogether vnprofitable to nourish an Infant. The former is begotten by the expression and refluxence of the blood from the womb to the dugges, as also by traction: this latter onely by the Traction of proper Aliment; the former cannot be generated before true conception, because there should be no vse of it before. The latter may bee ingendered in growne and ripe maydens, and well blooded men, whose bodies and vessels do abound with laudable iuices. This double kinde of generation of Milke, I gather out of Hippocrates his Bookes de natura pueri & de glandulis. The Nature, saith he, of womens breasts is very rare and spongy, and the Aliment which they draw vnto themselves they turne vnto Milke. This is the later kinde of generation.

The other he describeth in the same place. The Milke commeth from the wombe to the breasts, which after the birth must be the nourishment of the Infant: this the Kel presseth out and sendeth upward, being straightned by the growth of the Infant. Wherefore the blood is pressed or strayned, and so returneth in women with Child by a wonderfull prouidence of Nature from the wombe to the Pappes, and that as soone as the Infant begins to moue. After it is brought into the world there is no more expression made, but the blood floweth of it owne accord to the Pappes, according to his accustomed motion, which Hippocrates sheweth in these words, in his Booke de natura pueri. After a woman hath borne a childe, if shee also haue giuen sucke before, the Milke will arise into the breasts as soone as the Infant begins to moue: so that after the birth it is therefore led vnto the breasts, because it was accustomed to bee his course that way all the while the Infant did moue in the mothers wambe. Neither doth the blood onely of it owne accord presse vnto the Pappes, but they also drawe a greater quantity then is sufficient for their particular nourishment.

Of this Traction there bee diuers causes: the Infants sucking, the largenesse of the vessels, the motion or exercise of the dugs, and at length the auoyding of vacuity. For when the veines of the breasts are exhausted by the Childs instant sucking, then they draw blood vnto themselves from every side.

Wee conclude therefore that true Milke and perfectly concocted, is not generated before conception, but that there may be a thinne and raw Milke sometimes made of the reliques of the proper nourishment of the dugs.

QUEST.

QUEST. XXIII.

wherein certaine Problemes are vnfolded concerning
the generation of Milke.

Concerning the first generation of Milk, there is vpon record a solemne edict of Hippocrates in his Booke de natura pueri. As soone as the Infant beginneth to moue, the milke giveth warning thereof vnto the mother. For the explication of which sentence, there are two Problemes to bee discussed. The first, why at that time the Milke should begin to be generated. The second, why the infant should be nourished out of the wombe with the same wherewith hee was nourished in the Wombe. The resolution of the first question will haue some difficult passages in it. For seeing that the Milke is onely ordained for nutrition, and that therewith the infant in the wombe is not nourished, but onely after the birth, why is the Milke generated before the 7. month, til when there is no vse of it, or why doth it not flow from the womb to the breasts presently, or soone after conception as well as in the third and 4. months. Hippocrates in the booke before quoted, answereth this Question thus, *That the infant in the third or fourth month becoming great, dooth straine or presse the vessels which are full of blood, and by this compression there is an expression made vnto the upper parts.*

This reason is indeede very true, but verie subtile and obscure, wherefore we wil paine our selues a little to make it manifest. In the first months, Natures expence of blood is verie great. First of all, because the Parenchymata or substance of the bowels and all the fleshy parts are generated, and afterwarde for the nourishment and growth of them all, so that there remaineth little or no ouerplus of the Mothers blood. But when the infant begins to moue because there is already a perfect conformation of all partes, Nature thereafter onely intendeth nourishment, which nourishment requireth but a small quantity of Aliment, because there is but small and slender exhaustion or expence in the parts, and therefore in the veynes of the Wombe, there must needs be an ouer-plus of blood: These Veines being pressed by the motion & weyght of the Infant, which now is growne great, doe driue the blood vnto the vpper parts, and rather into the Dugges then into any other, as well because of the commodiousnesse and fittnesse of the way, as because of the societic and simpatie that is betwixt the wombe and the breasts. Add hereto a third cause which also is the finall, and that is the wonderful prouidence of Nature, whereby the blood is accustomed by little and little to be transported vnto the place where it shall be turned vnto Milk, and so remaine a plentiful fountaine for the nourishment of the infant after it is borne into the world.

And that is the reason why women are not so much troubled with bleedings at the nose, and with Hamorrhoides, because blood affecteth the way vnto the wombe, to satisfy the ende or intent of Nature, which is the generation and nourishment of an infant. Giue mee leaue also to giue another reason of this refluence of blood from the Wombe vnto the Dugges, which is, That the infant might haue occasion offered it to seeke a way out of the Wombe. For, if all the blood were still reserved in the vessels of the wombe, and no part of it discharged or sent away other whither, the Child would neuer strue to come forth, hauing alwayes nourishment enough at hande to content it: for Hippocrates saith, that the chiefe cause of the strife of the Infant in the byrth is the want of Nourishment.

It behooued therefore, that in the thirde and fourth Moneths Nature should by degrees transferre the blood vnto the Dugges to accustome her selfe to leade it thither for the nourishment of the Infant when it is borne, as also to defraud the infant (now becom'd better growne) of his nourishment, whereby hee might bee prouoked to seeke for it otherwhere. Some thinke, that the blood returneth vnto the breasts after the infant begins to moue, to bee kept as it were in store, that thereby at time of neede and in great want the infant might haue blood so prepared and whitened into Milke to sustaine his necessity.

And this Hippocrates seemeth to intimate in his Booke de Natura pueri, where he saith, *That the infant with this milke, is somewhat & sometimes nourished,* which saying of Hippocrates I do thus interpret, *The child is nourished with milke,* that is, with the blood conteyned in the veines of the dugs, which is the next and most immediate matter of the milke, or, if the infant should bee extreemly affamished before the time of the birth, I thinke that the

Another an-
swer.

Obiection.

Answer.

The conclusi-
on of these
controuersies.

The second Probleme was, why the Infant is not nourished with the same Aliment without and within the Wombe; for within the wombe it is nourished with verie pure blood, without the wombe with sweete milke. *Dinus* answereth, That the blood being hotter then the Milke, if it should passe all the three concoctions in a childs bodie, it would at length become vnmeet for nourishment, because by too much heate it would contract a bitternesse: but the Milke which is of a more cold temper is more easily mittigated, and groweth rather sweet then bitter by the threefold concoction. But is it rather an inhumane and beastly thing for children to be blood suckers: or shall we say that therefore the Infant after byrth is not nourished with blood, least by his sucking hee should open the mouths of his Mothers Veines, and so the blood which is the treasure of nature should flowe away?

And whereas some affirme, that after wee are borne, it is necessary that our Aliment should passe all three concoctions, and that it is not possible that the stomacke should chy- lific the blood, and therefore Infants are not nourished by blood but by milke: I say the reason is false and full of error, for whatsoeuer is taken vnto the stomacke, if it may be assimilated, it may also be turned into a creamy substance, and many there be who drinke the blood of Swine and Goats, the noysome excrements whereof are auoyded by the guttes and the seidge. Now the excrements of the guts, are onely excrements of Chylification.

Other things which may concerne this or anie other of the Naturall parts which be- long vnto Nutrition, because wee imagine that they are easilie knowne, or if hard yet ge- nerally agreed vpon, we do willingly passe ouer, iudging it sufficient that we haue thus long detained the Reader in these Labyrinthes of Controuersies, which notwithstanding as (it may be) they will not be thought necessary for all, so we presume that they will not be irkesome to any man, whose Stomacke standeth to these delica- cies of Nature, nor vnprofitable for those to whose proper element they belong. Now it is high time to returne to our

Of the Naturall Parts belonging to generation, as vvell in Men as in Women.

THE FOURTH BOOKE

The Preface.

BEing arrived at this place in the tract of my Anatomicall Peregrination, I entred into deliberation with my selfe, whether I were best silently to passe it by, or to insist vpon it as I had done in the former. On the one side I conceiued my labour would be but lame if it wanted this limbe, and a great part of my end and ayme frustrated, it being to exhibite the wonderfull wisdom and goodnesse of our Creator, which as in all the parts it is most admirable, so in this (if perfection will admit any degrees) it is transcendent. The whole body is the Epitomie of the world, containing therein whatsoeuer is in the large vniuerse; Seede is the Epitomy of the body, hauing in it the power and immediate possibility of all the parts. Moreouer, the knowledge of these principles of generation is so much more necessary toward the accomplishment of our Art, by how much it is more expedient that the whole kinde should be preserued then any particular. Adde hereto, first that the diseases hence arising, as they bee most fearefull and fullest of anxiety especially in the Female sexe, so are they hardest to be cured: the reason I conceiue to be, because the partes are least knowne as being veiled by Nature, and through our vnseasonable modesty as it is called, not sufficiently discovered. Againe, the examples of all men who haue vndertaken this taske euen in their mother tongues did sway much with me whose writings haue receiued allowance in all ages and Commonwealths. On the contrary there was onely one obstacle, to reueyle the veile of Nature, to prophane her mysteries for a litle curious skilpride, to ensnare mens minds by sensual demonstrations, seemeth a thing liable to heavy construction. But what is this I pray you else but to Araigne Vertue at the barre of Vice? Hath the holy Scripture it selfe (the wisdom of God) as well in the old Law particularly, as also in many passages of the new, balked this argument? God that Created them, did he not intend their preservation, or can they bee preserued and not knowne? or knowne and not discovered? Indeede it were to be wished that all men would come to the knowledge of these secrets with pure eyes & cares, such as they were matched with in their Creation: but shall we therefore forget our knowledge because some men cannot containe their lewd and inordinate affections? Our intention is first and principally to instruct an Artist: secondarily that those who are sober minded might knowe themselves, that is, their owne bodies, as well to giue glory to him who hath so wonderfully Created them; as also to preuent those imminent mischiefes to which amongst and aboue the rest these parts are subiect. As much as was possible we haue endeouored (not frustrating our lawfull scope) by honest wordes and circumlocutions to molifie the harshnesse of the Argument; beside we haue so plotted our busines, that he that listeth may separate this Booke from the rest and reserue it priuately vnto himselfe. Finally, I haue not herein relyed vpon my owne iudgement, but haue had the opinion of graue and reuerent Diuines, by whome I haue bin perswaded not to intermit this part of my labour. My hope therefore is that my paynes in this part shall receiue not onely a good construction, but also approbation and allowance of all those that are indeed wise.

As

the history of
these parts.

Obiection an-
swered.

How caute-
lous we haue
beene herein.

As for such as thinke there is no other principle of goodnesse then not to know euill, I would wish them to learne of their horses, that it is no good Manage to stand stocke still but to moue in order. We will apply our selues to our businesse.

The perfecti-
on of euerie
thing is per-
tuity.

What life is:

Comparison.

The greatest argument of diuinity, or of a nature relishing thereof is perpetuie and immutability, the perfection whereof as it is incompetent to any compound creature (for the soule is therefore immortall because it hath no parts) so it is most resembled in that we call *Life*; wherein there is a perpetuity though not of all the parts of time *Past*, *Present*, and *to Come*; (for Time is the measure thereof) yet of that which in time is subsistent, that is, the *Present*. For as the production of poynts perpetueth a line, so the coherence of *present* times make a kinde of eternity. Life therefore so long as it is prolonged hath no end, and may be compared to a clew of yarne, such as the Poets feigned Destinies to spin, which so long as there is flaxe to supply, may be drawne into an endlesse length. Now wee must know that the matter of all things is eternall for it neuer perisheth, else had the world long agoe beene annihilated. The dissolution of created things is but a resolution of one thing into another; hence comes the perpetuity of all things though subiect to alteration, a perpetuity I say, not of the same particular thing distinguished by one and the same *forme*, but of the Elementary parts whereof it was compounded.

The Element-
ary forme of
man.

How a man is
perpetuall:

The proceffe
of Nature in
the Frame of
man:

Comparison:

But some will say, this is but a speculatiue and imaginary perpetuity, shew it vs more really that we may see it with our eyes, & feel it with our hands. I shew it thus. The body of man consisteth of the matter and forme; by forme I mean, not the soule, but the forme subsisting in the matter, and arising out of the power of the same, which though it be not diuine nor aetheriall as some imagine, but meere materiall, yet so neere it approacheth to the puritie and nature of the first matter whereout it resulteth, that it easily vanisheth into an uncompounded principle, subsisting afterwards in Nature, not as a *forme*, being forsaken by the spirite wherein it had his residence and whereby it was nourished, but as a part of the vniuersall Nature.

This forme we call *Life*, which as it is raised out of the matter of the body, so it continueth so long therein, as it is supplied with nourishment, which nourishment is the radical moysture of the spermatie parts. Nature therefore being not able to generate anie part of seede whose moysture shoulde not in time bee exhausted, could not produce any particular creature eternall or immutable: notwithstanding she deuised a way by framing parts fit for multiplication of seede, to raise a perpetuity, though not of any particular *indiv-
duum*, yet of the *kinds* of all creatures. Those parts are the subiect of our present Discourse.

So then first of all she prepareth a matter euen the ouer-plus of the nourishment of the particular parts of our bodie. For the nourishment hauing arriued at the parts, and receiued an impression or stampe of their nature, is partly assimilated into their substance, part (at least if there be any ouer-plus when the part is satisfied) falleth backe by the Vesselles vnto the spermatie Veines and Arteries, which receiuing an irradiation from the Testicles to which they are continued, do giue that matter a kinde of Rudiment of seede. The lower it falls and the nearer it approacheth to these Testicles, the better is it still laboured, till in the end it receyue from them his vtmost perfection both in the colour, consistence, and prolificall vertue; being so accomplished, it is conueyed by the leading vessels into the Store-house called *Prostate*, where it is tunned vp and reserued for the generation of a new creature, which new creature when it is made, is also able to afforde matter for the generation of another, and so nature obtained a perpetuity and eternity euen out of mutable and temporary principles.

The like administration of Nature (though the proceffe of her worke bee not so long) we see in fruites, trees and plants, all of them being able to bring forth seede, which shall perpetuate their kindes; a seede (I say) which though it bee but small, shall containe in it a power to frame anew all the parts of the bodie from whence it yssued. So an Acorne hath in it the power of a mighty Oake. The quantity of an Emmet of seede, the power to grow into a vast Elephant. But because whattoeuer is ordained to bee made a liuing creature, must haue not onely one principle whereof it should bee formed, but also another whereby it might bee sustained and nourished, as also a conuenient place for the growth and extension thereof: Nature therefore (vnder which name I alwayes vnderstand the wise administration of almighty God) made another sexe of mankind, not altogether of so hot a temper or constitution, because she shoulde haue a superfluity of blood for the nourishment of the infant, as also that the partes of generation for want of heate to thrust them forth

foorth remaining within, might make a fit place wherein to conceive; breed and perfect the same.

why woman was made.

Againe, that there might bee a mutuall longing desire betweene the sexes to communicate one with another and to conferre their stocks together for the propagation of mankind, beside the ardor and heate of the spirits conteyned in their seeds, the parts of generation are so formed, that there is not only a naturall instinct of copulation, but an appetite and earnest desire thereunto, and therefore the obscene parts are compounded of particles of exquisite sense, that passion being added into the will, their embracements might be to better purpose. As for the particulars it shall be in vaine in this place to make mention of them, because the following discourse shall at large decipher them vnto you, in which we will first describe the parts of generation belonging to men, and then proceede to those of Women also; of which wee would aduise no man to take further knowledge then shall serue for his good instruction. And so we descend vnto our history.

The nature of the obscene parts.

Man's nature.

CHAP. I.

Of the Necessitie of the parts of Generation.

It is a ruled case in Hippocrates his Bookes de dicta, Aristotles Booke of the length and shortnes of Life, Galens first Booke de sanitate tuenda, and at a word amongst all Philosophers and Physitians: That all things vnder the Moone which is (sayth Cicero Somnium Scipionis) ultima Caelo citima terra, the last in Heauen and the nearest to the Earth; all thinges I say conteyned within the Elements are subiect to corruption and dissolution. For every singular and particular thing either hath life or is without it: if it be without life it is obnoxious to diuers alterations, in regard both of the first and second matter whereof it consisteth. For the first matter, it is alwayes in loue with new formes; and therefore most subiect to mutation, which the French Poet Salust expresth vnder the comparison of a notorious Strumpet, on this manner.

All Elementary things mortal, and how they are corrupted.

Salust du Bar.

Or like a Lais, whose vnconstant loue
Doth every day a thousand times remoue
Who's scarce vnfolded from one youths imbraces,
Yet in her thought another shee imbraces:
And the new pleasure of her wanton fire,
Stirs in her still another new desire.

The generall matter of things like a strumpet.

The second matter which consisteth of the Elements, because of their intestine discord (for they are contraries, and from contrariety comes all corruption) vrgeth continually the dissolution of the mixed body.

The Elements themselves whilst they are out of their proper places, although they bee naturally linked together, yet it is not without a kinde of violence and constraint, and therefore doe instantly long to retorne into their proper seates.

But if the body be animated and haue life, beside those already named, it hath also other causes of dissolution bred within it, which no art, no industry of man can auoyde, no not so much as repress: so all things which haue any kinde of life, especially liuing and mouing creatures are destined to corruption, by Nature and necessity. By Nature because of the exhaustion or expence of the Primigenie moysture by the Elementarie heat and the continuall effluxion of the threefold substance. By Necessity because of the permixtion of the Aliments and the increase of excrements, the suppression whereof maketh an oppression of the parts, stableth vp a fruitfull nursery of diseases, and finally introduceth death it selfe.

A double destiny.

By Nature.

By Necessity.

Wherefore Nature whome Hippocrates calleth τὰ δέοντα ποιῶσα Recta facientem, and the ordinary power of God, being a diligent and carefull provider for her selfe, hath giuen to euery thing a certaine appetite of eternity, which because shee could not performe in the Individuum or particular Creature, because of the mortality of their Nature, she induceth to accomplish by propagation of formes and the species or kinds of things; as in the Elements by transmutation of one into another, in Minerals by apposition, and in Creatures by Generation. For so euery individuum extending it selfe as it were, in the procreation of another like vnto it selfe, groweth young againe and becommeth after a sort eternall. The

father liueth in the sonne, and dyeth not as long as his expresse and liuing Image stands vp-
on the earth.

To passe by the production of other things, the generation of perfect creatures is ac-
complished when the male soweth his seede, and the female receyueth and conceyueth it.
For this purpose Nature hath framed in both sexes parts and places fit for generation: be-
side an instinct of lust or desire, not inordinate such as by sinne is super-induced in man, but
naturall residing in the exquisite sense of the obscene parts. For were it not that the God
of Nature hath placed heerein so incredible a sting or rage of pleasure, as whereby wee are
transported for a time as it were out of our selues, what man is there almost who hath anie
sense of his own diuine nature, that would defile himselfe in such impurities? what woman
would admit the embracements of a man, remembering her nine moneths burthen, her
painefull and dangerous deliuerance, her care, disquiet and anxiety in the nursing and e-
dication of the infant? But all these things are forgotten, and wee ouertaken with an ex-
tase, which Hippocrates calleth a little *Epilepsie* or falling sicknesse: and the holy Scripture
veilith vnder the name of a senselesnesse in Lot, who neyther perceiued when his daugh-
ters lay downe, nor when they rose vp.

Well, the History of these parts of generation it is our taske in this Book to describe, ouer
which also we could wish we were able to cast a veile, which it should bee impiety for any
man to remooue, who came not with as chaste a heart to reade as wee did to write. How-
euer, that which must needs be done, shal be done with as little offence as possible we may.

The parts therefore of Generation are of two sorts, some belong to men, some to women.
The parts of Generation belonging to men (for of the other we shall see afterwards) are
verie many, but all conspiring vnto one end, which is to exhibite something out of them-
selues which may haue the nature of a Principle; by which, and out of which a newe man
may be generated. The Principle exhibited is seed, which because it containeth in it selfe
the forme and Idea of all the parts (for it falleth from them all) and beside *μὴ ἴσως περὶ αὐτῶν*,
that is, the fatal necessity of life and death, stood in neede of manifold preparation, coction
and elaboration, and therefore the structure of the parts fit for so great and curious a worke
is no doubt very exquisite. For some of them do onely prepare the seede, or as it were
rough hew it, as putting thereon a rudiment of seed, which before was nothing else but an
ouerplus of the purer part of blood remaining after assimilation in the particular parts of
the bodie.

This preparation is made in the spermatieall Veines and Arteries, whose admirable im-
plications and complications like the wretched or wormie tendrils of veines, do forme as it
were a twisted or bedded net, wherein the matter is so long retained, till it acquire some
beginning of alteration from that it was before. Other parts there are which boyle it anew,
as that we cal *Epididymis* or *Parastata*, others affoord vnto it prolificall vertue, whereby it
is enabled to produce and generate a thing like vnto it selfe, & those are the testicles which
giue it the true forme of seede; others, when it is thus perfected, leade it downe toward the
place of receipt which are called *Deferentia* or *Eiaculatoria vasa*, albeit I see no great rea-
son for the second name, wee call them the *Leading vessels*. Others receiue, containe, and
store it vp for necessary vse as the many vesicles or bladderets, and those Kernels or Glan-
dules which are called *Prostata* scituated at the necke of the bladder of vrine. Finallie, o-
thers deliuer it out, and strew it in the seede plot, sowe it in the fertile field of Nature the
wombe of the woman; which is called *penis* the yard or virile member. Of all which, if but
one bee wanting, yea defectiue, the worke of generation goeth not at all or but lamely for-
ward, wherefore we will endeouour to shew you the naturall both position, disposition, and
vse of euerie one in their proper places.

CHAP. II.

Of the preparing spermatiecke or seede vessels.

Two sorts of
seede vessels.

Preparing:

THE first Instruments of Generation, are called *vasa spermatica*, the spermatiecke
vessels. These are larger in men then in women, and they are of two sortes,
Praparantia or *Deferentia*, Preparing or Leading vessels. The Preparing Ves-
sels [Tab. 2. 1. x. 2. tab. 1. 0. q. 1.] which are called *παραιωστικα* by Galen, by Au-
scen *vasa Lumbaria*, are foure. Two veines [Tab. 1. 0. q. tab. 2. 1. x.] and two Arteries, on each
side

side one [table 1, r, table 2, u.] The right veind ariseth [table 1, r, table 2, u.] a little below the originall of the emulgent [table 1, h, table 2, m, n.] from the vpper and forward part of the trunk of the hollow veine; as it weie with a long and thick knob or knot [table 1, p, table 2, a] (to which as *Galen* obserued, a certain small branch is conuayed from the emulgent) that it might afford more pure and better concocted blood.

The left [table 1, q, table 2, x.] ariseth not from the trunk of the hollow veine, but from the lower part of the emulgent; for if it should haue risen from the same place in the hollow veine where the right seede-veine arose, it must necessarily haue gone ouer the great arterie [table 1, g.] by the continuall motion of whose *systole* and *diastole*, that is, elevation or distention, and depression or contraction, being final, it would haue been either broken or much hindered from performance of his proper office, or else haue intercepted or offended the Arteries; both which inconueniences are auoyded by his arising, as we haue sayed out of the lower part of the left emulgent: [Table 1, i, table 2, u.] yet hath it sometimes a small branch reached vnto it from the trunk [table 2, v.] of the hollow veine; the blood also it brings is more *serous* then that of the right spermaticall veine.

The two Arteries arise neare one another [table 1, r, table 2, u.] out of the middle trunk of the great arteries a good way beneath the emulgents; that they might bring thinner and better cleansed or defecated blood. The right spermaticall Arterie climbing ouer [table 1, figure f.] the trunk of the hollow veine hastneth obliquely to the seede veine; the left closely accompanieth the veine of his owne side. And this Arterie we haue seene sometimes absent; and then the left seede veine is so much the larger; otherwise, generally these arteries are larger then their veines; because it was necessary that many vitall spirites and

much arteriall blood, should be conuayed to the Testicle, that when the seede is perfected, it might be fulfilled with spirit and vitall heate. It is obserued also, but more rarely, that in some bodies both the Arteries are wanting; and happely it falleth out so in them that are barren, for why there is no source of vitall spirits falling vpon their testicles.

All these vessels, the right veine with his Artery, and the left with his, not much parted one from another [Tab. 3. figure 2. 00] do beare vpon the *Peritonaeum*, and proceeding downward, are ioyned together with fibrous ties, [tab. 3. fig. 3. NN] and so passe along obliquely about the Vreters [tab. 1. fig. 1. mn. tab. 2. qq] allowing by the way certaine small branches [tab. 1. f. tab. 2. 0] to the *peritonaeum*, thorough whose productions (which firmly grow to their sides [tab. 2. 7. tab. 3. A] at the groin) they make way, together with a small nerue of the sixt paire, and the Cremaster Muscle [tab. 2. 4] and so far to the *Parastata* [tab. 1. u. tab. 2. 5] and to the vpper part of the Testicle, where the Veine & the Artery mixing together, do fashion out betwene them one body like a *pyramis* [tab. 2. from d to e] or spire depressed and plaine on each side. This bodie, because of the innumerable branches of Veines and Arteries ioyned by *Anastomosis* or inoculation, of which it is wouen as it were into a platted web, is called in Greeke *νεφροειδὲς παρὰ δῆς* by *Galen* in his booke de *Semine*, in Latine *Corpus varicosum* [tab. 1. 1. tab. 2. 8. tab. 3. Fig. 2. u. Fig. 3. C. sheweth the beginning of it, and D. the basis or foundation] the boddin bodye, and from the fashion of the tendrils of Vines *pampine-forme*, we may call it the *spirie boddin or embossed body*, to distinguish it from the *Parastata*, which are also called *corpora varicosa* or boddin bodies. [tab. 1. u. tab. 2. 6].

The vse of these vessels is not onely to leade downe blood of both sorts, Venall and Arteriall, together with vitall spirits for the nourishment and life of the Testicles; but also to receiue a matter or substance which falleth from al parts of the body; (the last and most perfect superfluity of the Aliment) some-what to alter it, and so to conuey it to the *parastata* for the generation of seede.

Moreover about the middest of these vesselles, the blood hath his first beginning of *dealbation* or whitening, yea, and a farther preparation also in those textures and webbes of which we lately spake, wherein by a kinde of irradiation the matter of the seede (as also the textures themselves) receyue vertue from the Testicles. Wherefore this spirie body cleaueth, yea groweth at his *basis* or foundation to the inmost coate of the testicle, bestowing vpon them certaine small furcles, but it entereth not into the body of the testicle, although some would haue it so, as *Vesalius* & *Columbus*, who also thinke that many of the forenamed branches do passe through, and are disseminated into the substance of the testicle, where their coates become exceeding fine and thin, that the power of procreating seede might the more suddenly and at once flowe from the Testicles into those vessels; like as in the Liuer the tunicles or coates of the veines disseminated through his substance are most fine and subtile, that the blood might more easily be altered and concocted in them by the force of the *parenchyma*. And so much of Preparing vesselles, now followe the *parastata*.

CHAP. III.

Of the Parastatae.

Their situation.

Their originall.

Galen.

Their forme.

THE *Parastatae*, so called because they stand by the sides of the Testicles, are also called *νεφροειδῆς*, because they are placed about the Testicles. They are bodies situate without the *Abdomen* in the *scrotum* or Cod, set vpon the Testicles [tab. 1. 11. tab. 2. 6] (to which they are alike both in nature and vse,) as yet wrapped in their inmost [tab. 1. fig. 1. x. tab. 2. 7] coate for their better safegard & defence, & are firmly tied to their head and bottome, but disioyned in the middle. These *parastatae* do arise from the spirie boddin body [tab. 1. 6. tab. 2. 8] by continuation, & creepe obliquely backward & downward to the *basis* or bottom of the testicle, & from thence are reflected or turned back againe vpward [tab. 1. fig. 2. 7. as] but without connexion or copulation, and being rowled as it were into a round orbe, carry the forme of the tendrill of a vine crumpled vp together: wherefore *Galen* out of *Microphylus*, calleth them *νεφροειδῆς παρὰ δῆς* in his 14. Booke de *usu partium*, and the 11. and 13. chapters. For they are white, long, thicke, and rounde, distinguished with certaine furlles or conuolutions like a wood-worme, and by degrees become narrower, determining on both sides into *Vas deferens* or Leading vessell which is like a round

Table 2. sheweth the lower Belly with the Share bones parted, that the vessels which serue for generation might the more plainly appeare.

The coat of the Testicle. ↓ The muscle of the Testicle ↓. his vessels ω.

round sinnew. Some there be as *Vesalius* and *Platerus*, who would rather haue them to be the beginning of these *vasa deferentia* or Leading vessels. And because their substance is a little more solid then that of the Testicles, they are esteemed to be of a middle nature betweene the vessels and the testicles, that is harder then the later, and softer then the former.

These *Parastatae* are also on their outside membranous and neruous, and where they are without conuolutions smooth they are and euen, but within glandulous, and if they bee cut they appeare spongy or spongy as if they consisted of many small glandules. But when they are separated and remoued from the coats of the testicle, as they may easily bee with a sharpe knife, then are they vnequall. They haue no pores or passages to bee seen in them; yet there bee that thinke (*Vesalius* among the rest) that they haue small pipes continuated with the Testicles, through which the spermaticke power arriueth vnto them out of the Testicles.

Their vse is either to hinder the seede not yet sufficiently laboured from falling downe out of the preparing into the leading vessels, or to labour the prepared seede to a further degree of perfection by the helpe of an irradiation they haue from the testicles. For they are often found full of seede, so that they may bee called not amisse, little stones or testicles. Again, they serue to temper and moderate the ouer frequent motion of inordinate concupiscence, as *Aristotle* conceiueth in his first Book *de generatione Animal. Chap. 4.*

neth no oily substance that might congeale into fat, because all the ouerplus when the testicles are nourished is changed into seede.

The second Common coate (called *Septes*, because it may easily bee separated from the rest) is produced from the fleshy membrane [Table 17. lib. 3. c.] where it is much thinner then in others parts, and replenished with Veines and Arteries: with both those coates are the Testicles inuelted and suspended, that they might not be iniured either with heate or cold, and so become vnfruitfull and barren. Also when they yarde is flaccid or loose they hang

downe, but when that rises or is distended, then the skin being also contracted and corrugated and with the yarde drawne vp, the Testicles also are suspended and drawne vpward; which ordinarily is obserued as a token of strength in young Children, who are often suddenly diseased; but if their Testicles be thus gathered vpward, it is commonly & not without reason, hoped that their naturall strength remaineth vndecayed; whatsoeuer the present cause or violence of the disease may be.

Why the corrugation of the Cod is a signe of strength.

The proper coates which doe inuelt each of the Testicles by it selfe are two, yet *Columbus* maketh three proper, and reprehends *Vesalius* for making but two. The first and vtter is called *inuentio*, that is, *vaginalis*, as it were the sheath or huskie membrane [Table 17. lib. 3. c.] where it appeareth whole; tab. 3. Fig. 2. II. tab. 2. at o x cut open] for so saith *Pliny*, Prouident Nature hath inclosed all the principall bowels, *membranis proprijs ac veluti vaginis*, that is, In proper membranes, as it were corne in the huskes. It is also called by *Paulus* from the

Their proper coates. The first and vtter.

Paulus

fashion

fashion it carrieth *ἐλκροειδής*, or *Capreolaris*, that is the Tendrill. It ariseth from the production of the *Peritoneum*; it is thinne and strong, and outwardly groweth to the *σάρτιον*, fastened with a multitude of membranous fibres [table 17. lib. 3. from *n* to *t*,] which *Columbus* thought to be a particular coate, yea & some fibres there are which ioine the husky coates of both the Testicles together. Inwardly it is also thinne but lined with a watery humour and aboundeth with veines. To this coate sometimes are added certaine small fleshy fibres (whence it is called by *Oribasius* the great Abreuiator of Antiquity *ἐρυθροειδής*, from *ἐρυθρίαι*, which signifieth to grow red; for such is the coate where these fleshy fibres are) which goe vnto the bottome of the Testicle.

The vse of the vter coate. The Vse of this Membrane is thought to be, that whilst it inuolueth the stones as it were within a huske or sheath, the spermatike vessels are closely knit vnto them; or that there might be an infusion of imperfect seede into the Testicles out of the vessels, or rather, that from the Testicles some force or faculty might reach vnto the vessels.

The second & inner coate of the testicles. The second or inner proper coate of the Testicles (called by *Vesalius* and *Archangelus* *ἐπίδιδυμς*, because it immediately encompasseth the Testicle, in Latin *Albuginea*, the white coate [Table 2, 3. table 3, figure 2. n. figure 3. QRS] which ariseth from the coate of the spermatike vessels) is white, thicke, and very strong; whence *Raffus Ephesus* calleth it *σκληρὸν καὶ πρὸς οὐσιν*. It immediately inuolueth the substance of the Testicle, that it may firme, stay, and as it were knit together his soft and laxe flesh [table 3. figure 3. r.] least otherwise it should haue beene too loose, and so haue proued vnprofitable; as also that by his interposition as it were of a meane or middle nature, the harder vessels might more fitly grow and apply to the softer substance of the testicle.

Their Figure. The Testicles are round of an ouall figure saith *Laurentius*, or like eggs depressed or flattened somewhat on either side; and they hang obliquely or sidelong because of the vessels which grow vnto them, and because of the protuberation or bunching out of the *Parastata*, as if they were two small stones; which protuberation in lasciuious men is not vnusuall. The vpper bunching part is called by *Aristotle* & *Galen* *κεφαλὴ* the head, the lower which is blunter and larger is called the bottome; by *Pollux* *πυθμὴ*. The right is the hotter because of his vessels which transfer from the hollow veine and the great arterie more pure and sprightfull blood vnto it: it is thought also to be more bodden or embossed, and the seede on that side is thought to be better concocted, albeit *Vesalius* denyeth any difference, who doeth not conceiue that the procreation of Males and Females dependeth vpon the greater or lesser implication of these substances. Yet *Hippocrates* calleth the right *ἀρρενόγονος*, that is, the Male Testicle, and the left *θηλυόγονος*, the female Testicle which is fuller of seede then the other, but that more weake and waterish, hauing most of his matter from the emulgent; whence it is that the Nature of women seemeth to be more intent vpon generation then that of man, euen from the very beginning: witnesse the childish disports of young Girles in making of Babies, Nursing, and lying in, as we say, and such like pastimes, wherein they are occupied euen from their infancy.

These Testicles being ioined by the interuening of membranes, do hang downe from the sharebones and the yarde.

Their substance. The substance of the Testicles is glandulous, white, milky, soft, laxe or loose in men and spongius, because of many small veines [table 3. fig. 3. u u] dispersed through their bodies, but yet there appeareth no cavity or hollownes in them.

Muscles. They haue on each side one muscle and that a long one [table 2. v. table 3. figure 2. x] and slender, beginning at the hanch bone, or rather from a strong ligament which runneth from the hanch to the share-bone in that place where the transuerse muscles of the lower belly doe end, of which these muscles seeme to be a part, and they get out by the out-let of the Tendons of the oblique muscles, and outward neere the leskes they grow to the vessels which attaine vnto the Testicles and vnto the heades of the Testicles themselues. Sometimes from the forepart of the share-bone there are certaine fleshy fibres communicated vnto them, so that they may be obserued to haue (as they haue alwayes in Apes) a double originall.

By the benefite of these muscles, the Testicles which are pendant, are suspended or hung (whence they are called *κρεμαστές*,) that they should not bee a burthen to the spermatike or seed vessels as we touched before. Moreouer in copulation or coition they draw them back, that the seed-trough becoming shorter, the seed may more easily and readily be supplied. And *Galen* in his fourth booke *de usu partium* and the 14. Chapter sayeth that they

partake of voluntary motion.

For their nourishment and life the Testicles receive matter from the spermatike [table 2.] veines and arteries. How then may some say are they nourished with blood? I answer, as the Paps are nourished with Milke; for their blood is not red but turned into Milke and Seed; as also the bones are nourished with marrow. For all the parts of the body are nourished with blood, either red or turned into a substance more convenient for the part which it is to nourish. A reasonable nerve also they have, from the rib branch [table 6. lib. 2. fig. 1. iii.] of the sixth paire, sometimes also two other nerves arrive unto them from the 21. coniugation of the marrow of the loynes (that hanging out of the body they might not yet be deprived of exquisite sense) which after being ioyned to the spermatike vessels are carried downward, and implanted into the coats of the Testicles.

Their vessels by which they live.

The use of the Testicles is (for that without them neither can seed be ingendered nor any absolute Creature perfectly generated) by their inbred faculty to give to seed not so much the colour (for it falleth not into the substance of the Testicles as Vesalius and Laurentius do suppose it doth) as the very forme and generating power, and that so strong and vigorous, that a perfect and absolute Creature out of it may be generated; which power in men is the cause of virilitie, and in a woman of womanhood or muliebritie. Moreover by reason of this faculty the Testicles are esteemed the prime instruments of generation, and also by some, Principall parts of the body.

The use of the testicles.

They adde also to the body much strength and heate as appeareth by Eunuches, whose temperament, substance, habit and dispositions are all altered, as we shall heare hereafter, and that because of the great consent of the vpper parts with these Testicles mentioned by Hippocrates in his second Booke Epidem. and the first section, in these words, *when the Testicles doe swell upon a Cough, it putteth vs in mind of a sympathy and consent there is between the Chest, the Paps, the Seede, and the voice.* And how great the consent is betwixt the parts of respiration and the parts of generation, he sheweth in the fourth Book Epidem. and the last Aphorisme saue one, on this manner. *They are troubled with a dry Cough whose Testicles doe swell, and that Cough endeth in the tumor of the Testicle if a veine be opened; and when the Testicles are inflamed men do Cough much.* And againe, *Those that are agueish with tumors in their leske, haue Coughs follow them continually.*

Their consent with other parts.

Of their consent with the chest.

For the consent of the Testicles with the head, I can give you a notable instance of a wanton young fellow, who vpon a small and almost insensible tumor (especially at some times) in or about one of his Testicles, fell first into light, and after into extreame fittes of the Epilepsie or Falling sicknesse, whose name I suppress, not for his desert toward them that deserved well of him, but for the reuerence of our Art.

The head. A story worthy the observation.

Finally, in excellency the Testicles are like unto the heart: for that Cordiall Epithymatics applied to the Testicles in great languishments of the spirits doe little lesse auaille, then if they were applied to the heart it selfe.

The heart.

CHAP. V.

Of the vessels called Vasa deferentia, or Leading vessels.

 THE Vessels which Leade the seede called vasa deferentia [Table 3. Figure 3. H I, separated from the Testicles] are called by Herophilus ὁδὸς σπέρματος, by Fallopius, Canalis seminaris, the seede-cane.

They are situate partly without the Abdomen in the scrotum or Cod, partly within the cavity or den of the Hip-bones on either side one, at the head of the testicle, and are produced from the Parastata, to which they are continued, [tab. 1. fig. 1. p. 2. b.] as also are the preparing vessels, [tab. 1. figure 1. f.] although their names be diuers according to their distinct offices and situations.

Their situation.

Their substance is nervous and crumpled or writhen, [tab. 2. a, the descent of the Leading vessels, from i to r the reflection or turning of it; and [table 1. fig. 2. y, is the originall of this vessel, his descent at a, his revolution at b. [tab. 3. Fig. 3. from E to F downward] contorted at the lower end of the testicle; but where they are parted from the Testicles, they are round and white, and their cavity or hollownesse is but obscure [tab. 3. fig. 3 H sheweth the porous surface of the leading vessel, where it groweth to the couering of the Testicle]

Their substance.

Connexion.

neyther needed it to bee more open, because the seede by reason of his abundance of spirites wherewith it riseth and houeth or worketh vppe, can easilie passe thorough.

Progresso.

They arise vppward [table 3. fig. 3, G] and are tyed to the preparing vessels [Table 2. at 2] by the mediation of a thinne and small Membrane, presently after (by the same way by which the preparers descended) they are carried through the productions of the *Peritonæum* [table 2. at 9, table 3. figure 2. 0. 5] to the share-bone, at which place the bone hath a superficialie cavity [table 2. 6, lib. 3. figure 12, 13, 7] which giueth way vnto the roundnesse of the vessels.

Vniting.

After being returned downward [table 1. figure 1. from 7 to 5, tab. 3. fig. 2. 7. 5] like Nerues, and tyed on the backe side (where the humour they containe is now become white) to the *Peritonæum*, they are led ouer the [table 3. figure 2, 11] Vreters, and vnder the backe side of the bladder about the right gut neere vnto the necke of the Bladder; a little before they vniting together [table 1. figure 2. 8. and table 3. figure 2, 7, is the vniting of Leading vessels] they are on eyther side dilated and become thicker, where these small Bladderets of seede [table 2. fig. 1, 22] called *Vesiculae Seminae*, are adioyned vnto theyr sides, but the Leading Vessels themselues are spent, the right into the right, the left into the lefte *Prostate Glandule*. [Table 1. fig. 2. 11. table 3. figure 2, 9]

Their vse.

The vse of these Leading vessels, is to carrie or leade the seede after it is laboured in the *Parastatae*, and made fruitfull and prolificall by the Testicles, vnto those *Prostate Glandules*, as it were vnto certaine Magazines or Store-houses, where the right Vesselle meeteth and coupleth with the lefte, that the seede of each Testicle might together and at once bee thither conueyed, and so shot together into the Wombe by the Virile Member.

Moreover, their oblique passage furthereth much the seedes perfection; for as in making of *Aqua vita* or such like strong spirits of wine, wee see the liquor first ascendeth and then descendeth, so the seede being to become a frothy body, did of necessity require such sublimation and precipitation to make it absolute and perfect.

CHAP. VI.

Of the Bladders of seede.

What the bladders of seede are.

He small bladders of seede [table 1. fig. 1. 22, shew them open] are placed betweene the Ligaments of the Bladder of vrine and the right gut at the sides of the leading vessels a little before they become thicke and are vnited. They are compounded (saith the Author of the Definitions) of a veine and an Artery mixed together. They are on either side one, neruous, large and sayre enough to be seene, hauing not as other bladders one cavity, but are full of boughtes and turnings like burst or knotted

Why created

veines, implicated or folded one within another (and therefore *Herophilus* calleth them *παράστατες νεφροειδείς, Adstites varicosos*) so that they seeme to be many, and in them (saith *Fallopins*) seede may be kept many months. For Nature being desirous of the continuance and perpetuie of mankind, ordained, that all times should be fit for their procreation, and therefore it was verie meete, that a matter rightly for that purpose disposed, should at all times be readily supplied, but because man coulde not alwayes entend that worke, and yet it was necessarie, that euen this excrement or surplusage should be auoyded, therefore like other excrements it also was to bee gathered together in some place and there kept till a fit occasion were offered, that from thence it might bee shot forth.

Varolius.

And for this purpose (sayth *Varolius*) these Bladderets were created, into which the seed should bee continually emptied out of the Testicles, and therein stored vp against the time of expence.

Their vse.

But least so great a quantity remaining in one place should corrupt, there are many turnings and windy boughts and passages in them, which also are a stay vnto the Seed, that in one Coition or accompanying of the sexes, al the seede should not bee spent. For, the seede winding it selfe out of those manifold Labyrinths by degrees, doth passe away more safelie and moderately, and with better stay and deliberation.

Banhsine.

But we (saith *Banhsine*) haue hitherto obserued that these bladderets are full of a yellow oily humor wherewith the passage common to the seede and the vrine is illined or smeared least it should be hurt by the acrimony of either of them, or least when it is drie it should

close

close together, and so hinder the next euacuation. For to this end in copulation this oyli-
ness together with the seede yssueth sensibly and feelingly, at other times it wellet out
insensibly; *Galen* addeth in the 14. Booke de *usu partium* cap. 11. that it prouoketh lust, and
keepeth moyst the necke of the bladder of vrine.

CHAP. VII.

Of the Prostata.

The Prostata as it were fore-standers, are called by *Herophilus* *σποδάριος* and *σποδάριος*. *Columbus* calls them *Parastata*. *Fallopian* calleth them *assistant Glandules*.
Varolius two Testicles smaller then the other. *Vesalius* out of *Galen* calleth
them *σποδάριος*, that is, Glandulous bodies. And so indeede they are
two Glandules [table 1. fig. 2. m.] on either side one, placed in the cauitie of
the Abdomen at the lower part of the bladder [tab. 2. e] that is, in the necke about the sphin-
cter [tab. 2. p. tab. 1. fig. 2. d] Muscles, or rather betwixt the necke of the bladder, and the lo-
wer Muscles of the yard at his roote, where the Leading vessels are vnited. [tab. 1. fig. 2. d]

These Glandules are depressed before and behinde, but round on the sides, into which
as it were into other testicles, the leading vessels do end.

They are couered with the Membrane which did inuest the leading vessels, but now be-
come somewhat thighter, least the substance of these Prostata being rare and spongie, the
seed should soake out of it owne accord through their open pores, albeit they be very nar-
row. Yet is this Membrane verie thin, and hath in it verie blinde breathing pores, which at
the first sight are not conspicuous, but when the Glandules are pressed, they appeare, for
by them the seede may be scrused in notable quantitie into the common passage, as it were
by grains or like smal seeds, euen as we see Quick-silver passeth through leather wherein it is
fast tied, if it be strained, whence also in coition great pleasure ensueth; the exquisit sense of
the membrane being tickled in the passage with the gentle and pleasing acrimony of the
seed.

Their substance is hard, spongie, and whiter then the rest of the Glandules, they are also
large, as containing in them so much seede (saith *Archangelus*) as will serue for the procre-
ation of foure or five infants; three or foure (saith *Columbus*) in those that are fruitful. And
therefore it is no wonder (though *Aristotle* writeth it for a wonder) that a Bul after his testi-
cles are cut off, may get a Calf. *Vesalius* hath obserued that the prostate glandules are noto-
riously large and full in Monkeys; and indeed they are of all creatures the most lasciuious,
as we do not only reade in authors, but haue also seene by the great Baboons which were
heere to be seene among vs; for they would in a manner offer violence euen to a woman. It
is therefore a very wicked and inhumane thing for Gentlewomen to cherish any kinde of
them in their bosoms yea in their beds, as I haue seene some doe with mine owne eyes.

The vse of these prostate lay some, is to add somewhat to the generation of seed, and their
reason is, because there is no where found so great quantity of it as in them: but if this were
true then euen gelded creatures would engender seed, and seeke to auoid it, which *Galen*
worthily gainsaith. *Varolius* seemeth to countenance this conceit, who saith, that in the
end of the leading vessels there are placed two other small testicles, which giue vnto the
seed his vttermost absolution or perfection, the leading vessels ministering vnto them, as the
preparing do to the Testicles.

Their true vse is to receiue from the leading vessels the seed now sufficiently laboured &
made prolifical or fruitfull, and to keepe it till the time of profusion or spending as we say. It
may be also they make it more thick as adding the last hand vnto it, for it appeareth in these
thick and white, in the testicles but thin and serous: sure it is, that the seed neuer procureth
pleasure till it come from them, witness those that are immoderate wantons, who spende
themselves so frequently that there is no time for the seede to bee stored vp in these parts;
their minds indeed are more then brutishly lustfull, but their bodies are not so delighted as
other more moderate men by their owne confession.

These Glandules being pressed on their backe sides by the lower Muscles of the Yarde,
[Tab. 4. fig. 1, and 2. H I] which arise from the sphincter of the fundament, [Tab. 4. fig. 1, M]
do constrain the seede into the common passage [Tab. 4. fig. 2. G] which in the fore-part of

A story out of
Vesalius.

Vesalius telleth a tale of a fellow that was hanged at Padua in Italy who had the running of the reines, in whose body euen after his death all these passages were manifestly open and free, especially those of the leading vessels into the neck of the bladder. Moreouer with their solid and firme substance they support the neck of the bladder, that it should not faile or fall, that so those narrow passages, and for the most part insensible which attain vnto the end of the necke of the bladder, should bee kept streight, that the eiaculation of the seede might not be interrupted in the excretion, although the fall of this doe stay the yssue of the Vrine.

CHAP. VIII.

Of the yard or virile member.

The names.

THE Yard is called in Latine *penis à pendendo* of hanging, and *Virga*; in Greeke *κavλός*, and by an excellency *μόριον*, that is, *virile membrum*, the virile member, because of the fecundity thereof. Many other names it hath both in Greek and Latine, a Catalogue whereof *Laurentius* hath putdowne vnnecessary for our turne, wherefore we haue spared our owne labour and your eares. The scituation is well knowne to be at the bottome of the lower venter on the outside [tab. 4. fig. 1, 2] as neere the fundament as it wel might, and not be troublesome by falling vpon it in the time of seidge: Not about the groine, or in the *Hypogastrium* or watercourse, because there is no bone to establish his originall. It was therefore necessarie it should arise at the very roots of the share-bones, as well for the establishment thereof in the act of generation, as also that it might be more fit to meete with the womans lap, and yet no hinderance to the actions of other parts. And because it was not necessary there should be more of them then one, it is placed alone in the midst. Long it is, [tab. 4. fig. 1, 2] round but not exactly, for the vpper side of it, which they call the back, is somewhat broader, and endeth in a dudgeon or blunt point. The length and thickest of it is diuerse, as well in respect of the kindes or species, as of the particular creature or *indivium*. In respect of the kinde, it is of such a length and magnitude as the necessity of the kind requireth for procreation: but in men shorter then in many other creatures, because men doe vse *aduersam non auersam venerem*. Of the *indivium* or particular, because it is formed comonly according to the proportion of the members, yet sometimes it is large in a little man, because of the abundance of the portion of the fathers seede of which it is framed, for the seede falleth from euery part of a mans bodye, and carrieth in it power of generating that part from whence it fell. Although *Galen* in his sixth Booke *de locis affectis* towards the end, writeth, that continence makes it to encrease, at least in thicknes. It is thought also it will be longer if the Nauill strings [tab. 4. fig. 7. VV X] bee not close knit by the Midwife when the childe is new borne; and that because of a Ligament which commeth to the Nauill from the bottome [table 4. fig. 7, X] of the bladder which they call *Krakhos*, for the straighter that is tyed vnto the Nauell, the more the bladder and the parts adioyning are drawne vpward.

of the yard.
Galen.

How to make
it long.

The coates.

The parts of it

That part of the yard which hangeth out of the *Abdomen*, is couered with a cuticle and a skin not very thicke (which is laxe or loose when it hangs, but in erection is stretched) equall to his length, and knit vnto it at the lower part of the *glans* or nut, it is also couered with a fleshy membrane which heere becommeth neruous. There is no fat betweene the coates, least the member should grow by that meanes too great, and so his action be hindered, or too soft which would hinder erection.

It hath two parts, the one next to the belly which is the more principall, and hangeth not out, and it is called *σπέρμα*, which is below the commissure or ioyning of the share bones, to the middest of which it is fast knit in the *Perinaum*, (that is, the space betweene the cods and the fundament) with strong Ligaments and Muscles, and arising vpward vnder the testicles, appeareth round about the *scrotum* or cod.

The other part of the yard is called *σπέρμα*, and hangeth downe without the body from the vpper part of the share-bone if it be flaccid, or if it grow strong & rigid, it is raised vpward and so stands commonly so farre from the body, as the necke of the wombe is in length in-ward

ward, that so it may yeeld seede vnto the very orifice of the wombe for the propagation of mankinde.

The structure of this member is such as is fittest for his vse and the necessity of Nature. The structure.
Why not a
bone. It is not bony, as in a Dogge, a Wolfe and a Fox; for so it would not be a pleasure but a great trouble to the other sexe, besides, being alwayes rigid or stiffe it would haue beene both vncomely and haue hindered many actions and postures or positions of the body.

It is not gristly or *Cartilaginous*, for then it could neither haue beene distended (for a Gristle. Cartilage hath no cauitie) neither could it haue beene soft and pliable.

It is not of the Nature of a veine, for then it could not so soone haue beene filled and Veine. emptyed againe; as also for that the simple coate of a veine would not haue endured any strong streatching.

It is not of the nature of an Arterie although that haue a thicke and hard coate, because Artery. of the continuall pulsation, vpon which a man cannot lay a law when he pleaseth.

It is not neruous, because Nerues haue no manifest cauitie, neither are they naturally Nerue. dilated; beside that, the softnes would haue hindered the tension or erection.

It is not a Ligament, although that would haue been fit for tension or erection, because Ligament. then it should haue had no cauity; and being beside without fence, it would not haue beene capable of pleasure.

It is not a Tendon, because they haue no cauity, and are beside softer then Ligaments, Tendon. and so not so fit for erection.

Much lesse could it well be made of flesh, or glandules, or muscles, or membranes.

It was therefore requisite that some other peculiar substance should be found out, such as was not else where in the whole bodie, that should be hard & hollow, that without difficultie or inconuenience, might successiue at conuenient times according to the presence or absence of the spirits bee rayed vp, or againe sinke or settle downe; and of so exquisite fence beside to breede that pleasure, whereby man is prouoked to rush into so obscene a peece of businesse.

Of such sort and structure therefore there are two bodies [table 1, figure 2. ii, table 4. How the yard
is construed. figure 1, 2, 3, 4, 5, 7, 9. *AB*] which together with the Cannell or passage doe make the yarde. They are hard, neruous and like ligaments, on either side one, arising from the lower part of the share-bone [table 4, figure 2, 3. *CC*] where it is thicke and round, and the vpper part of the *Coxendix* or hanch, as well that hauing a substance partaking somewhat of a bone, the yarde might bee better disposed to rigiditie, as also hauing his originall for a stable body, it might bee kept stable and straight in the performance of his action to which it is by nature designed.

These bodies are on the outside round, on the inside plaine, and below at their originall The 2. bodies. are diuided [table 4, figure 4. and 5. *EE* the two bodies, and *G* the canale or pipe] that they may yeeld way vnto the passage which commeth from the Bladder; by and by they are carried vpward, and about the middle of the share-bone they are ioyned together [table 4, fig. 4, 5. *F*] yet so as they seeme to bee distinguished by a white Line running in the midst of them if the yarde bee cut ouerthwart. [table 4, figure 4.] From thence they are returned downward to the Nut [table 4, figure 4, 7, 9. *D*] and doe inwardly end in an acute angle, and together with the canale or pipe doe fashion out the length of the yarde.ouer those ends groweth the substance of the glans or nut, and so the whole figure doth in some sort represent the greeke ζ , which therefore ought to be obserued because of the vse of the Catheter The Catheter. in the suppression of the vrine. For if the Catheter be not insinuated or gently put in with a kinde of dexterity, it either hurteth the pipe or the necke of the bladder so that bloud will follow, or else it will not passe into the cauity of the bladder.

The substance of these bodies is excauated or hollowed like a pipe (from whence they are called the hollow nerues) but of a fungous or spongy matter [tab. 4. figure 4. 5. *EE*] and filled with blacke bloud: so that naturally it is blackish. A remarkeable obseruation for A good note
for Chirurgi-
ons. Chyrurgians, that in the section of a putride yarde, they doe not take that for rotten which indeede is but Naturall; the want of which knowledge I am perswaded hath cost many a man a good ioynt, which otherwise might well haue beene saued. It is also wouen like a Net made of innumerable branches [Table 1. figure 1. ii, table 4. figure 5. *b*] of veines and The vessels of
the yarde. arteries diuersly intangled together which are very notable vessels, and arise here from the region of the great or holy-bone [tab. 8, Lib. 3. *tt.*]

These bodies are also rare and porous, that they might suddenly bee filled with spirites and

The vse of
the structure
of his bodies.

and with venall and arteriall bloud when the yeoman is irritated or incensed; and his violence being appeased, the same spirits and blood being partly dissipated & partly returned into the vessels, settle and shorten again. For if the member were alwayes strong and stiffe, it would be a great hinderance to men in many labours of this life, especially such as are violent, and beside it selfe would bee alwayes subiect to mischietes, euen as the arme or hand would be if it were continually streatched forth. On the other side, if it were alwayes flaccid or loose, it would be vnprofitable for that imploiment for which God and Nature haue ordained it. Wherefore onely in the time of coition it ought to bee swolne and rigged or erected; swolne and extended to a iust magnitude that it might fill the necke of the matrix, *ita ut utriusq. pudenda incalescant*. For it is mutuall heate which calleth and prouoketh the seed out of the inner parts; Rigid and straight not onely *ad commodiorem coitum*, but also that the passage being open and direct, the seede might more freely and directly bee eiacted or shot forth from the very *Prostata* wherein it is contained. For if it were either oblique or crooked, (as it is in those which are called *υποσπασιας* in whome the passage is retorted by reason of a bridle at the end of the yarde, who therefore cannot procreate vnlesse that bridle be cut) or did in any place not stand open but fall together, then would the seed stay or make stop in the passage.

The coates of
the yarde.

But againe, least the spirits which flow vnto it, and by which it is distended, should bee too soone dissipated or scattered through the fungous or spongy substance, it is couered and strengthened with membranous coates thight and very strong (which some men imagine doe arise from the commixtion of those vessels which passe vnto the yarde,) which are therefore called the neruous bodies of the yarde, and they are also thicke and substanti- all, that they might more easily be distended.

Comparison.]

For when as in venerious appetites, the bloud and the spirits do in great quantity assem- ble themselves out of the veines and arteries, that member is as it were a gutte filled with winde, presently swelling and growing hard; which no question commeth to passe when as the sphincter muscle (which encompasseth the necke of the bladder, the roots of the bod- ies of which the yarde is made, and the ends of the guttes) is contracted and presseth out the spirits abounding in those parts, vnto the yarde; for so wee see the iugular or veines of the throate to be distended, when in laughter the chest is compressed and straightned. So also the veines of the arme by reason of the constriction of a Ligature or tye are distended and growe hard and full: so then it appeareth that voluntary motion is not onely requisite for erection, but also for induration.

The pipe of
the yarde.
Galen.

The Pipe or Canale of the yarde [*tabl 4. figure 1, 4, 5, 7. G*] which in greeke they call *επι- σπασ*, the vrial pipe, or as *Galen* in his 15. Booke of the vse of parts and the 3. Chapter, the *spermatike pore*, commeth from the bladder [*table 1, figure 1. A* from the bladder *e table 4. figure 6.*] whose necke is long. This Pipe scituated vnder the bodies of the yarde [*Table 4. figure 4. and 5. G* vnder *EE*] is reflected together with them (in which reflection or retur- ning if putride or rotten seede in a *Gonorrhoea* or Running of the reynes, doe subsist or make stay, it there vlceraeth the passage) and becomming in the middle betweene them, it pas- seth along the length of the yarde vnto the outside of the Nutte; where it is embraced by those bodies ioyning together [*table 4. figure 4. 5. F*] in narrow angles, and so maketh the whole yarde perforated as was necessary for the emission of seede.

How the seed
putrifieth in a
Gonorrhoea.

The membra-
nes of the pipe.

This Canale or Pipe hath two membranes (of which none almost of the Anatomistes make any mention, saue *Bauhine* onely, and *Archangelus* of the inner) one inward and thinne wherewith also the nut or glans is couered, bred out of the thin meninx or *pia mater* of the braine, which inuesteth the nerues of the yarde, in which certaine circles are to be seene; & beside there is in it an exquisite fence to make it capable of the pleasure which the seed in his passage through it stirreth vp, and againe it circumscribeth or limiteth the circumfe- rence of the Canale or pipe.

The other Membrane is outward and fleshy, compounded of transuerse fibres for the better expulsion of the seed and vrine.

The middle substance of this pipe is lax [*table 4. fig. 6*] fungous or spongy and blackish so that it readily distendeth it selfe together with the neruous bodies in the effusion of seed, and againe as readily falleth in the euacuation of vrine.

A common
passage.

This passage is common to the Seede, the oylie humor issuing from the small bladders before spoken of and the vrine; and in the forepart of the Nut it hath a yawning out-let, by which these substances are auoyded. It is narrow in young folk, in others so much broader

aa 7. The veine and artery of the yard.

bb 5. The artery distributed through the bodye of the yard.

der as the skin is more or lesse retracted or drawne backe from it. *Vesalius* maketh mention of a student in the Law at *Forum Iulij*, who had two distinct passages, one for vrine another for seede, but that is indeede very rare. For, because the bladder was scituated so neere, it was not necessary that another passage should bee made for the auoyding of vrine, but Nature contented her selfe to vse that already provided for the effusion of seede. Wherefore the necke of the bladder is carried vpwarde from the Fundament, vnto the beginning of the yard.

But because these offices are perfourmed by voluntary motion, it was requisite that it should also haue Muscles. It hath therefore diuers Muscles, of which no doubt *Galen* wrote precisely in his Books *de Anat. administrationibus*, but we haue lost fise Books and a halfe of that worthy labour, beside other peeces of excellent vse, as wee may gather by those that remaine. In the fifteenth Booke *de vsu partium*, he reckoneth but two Muscles of the yard, which saith *Vesalius* I could neuer finde. *Laurentius* describeth foure, so will we also according to *Baubine*. Two Collaterall on each side one, which do arise neruous from the appendix of the hips, [Tab. 4. fig. 1, 2, K L, in the first figure they cleaue to their originall, in the second they hang downe to their insertion] below the originall of the bodies whereof the yard

A strange thing observed by *Vesalius*.

Two collaterall musles.

yarde is made; afterward they become fleshy, short and thicker then those that follow; and being obliquely carried vpward, they are inserted into the bodies of the yarde not far from their originall [Table 4. fig. 2. c c] and being together contracted in the act of generation, doe bend the yarde and sustayne it whilest the worke be performed; as for the erection it selfe, we haue sayed before it is made by a voluntary constriction of the sphincter muscle of the fundament, driuing the blood and spirits vnto it. *Columbus* also saith that these muscles haue some vse in our making water.

Columbus.

2. Inferior.

The other two muscles of the yarde are called *inferiores*, because they are scituate vnder the pipe, [table 4. figure 1. 2. H I. in the first figure they appeare yet cleauing vnto it, but in the second they hang downe from their originals] on each side one, arising fleshy from the sphincter of the fundament. [table 4. figure 1, M] They are somewhat long, and are on their insides vnited and so carried along directly vnder the Canale, and implanted at the sides [table 4. figure 1, G] of the same, (and being diuided one from another, doe a little embrace the bodies of the yarde) that they may dilate the lower part of the Canale on both sides drawne downeward, the yarde remayning erected, and so make it shorter least in the repletion of the neruous bodies, especially in the oblique reflexion of the yarde, that passage should be stifled and so the issue of the Seede hindered, which comes indeed leaping forth, and yet is continued one part of it with another as a company of Antickes holding hand in hand, do vault vpon a stage.

Comparison.

The vses of the
Muscles.

Moroouer these muscles do presse the Prostate glandules [table 4. figure 3. and 7. RR] and straine the Seed that filleth them in the time of eiaculation through their membranes by graines as wee sayed before, into the Canale where they are all mingled and issue together.

In miction also or making of water the muscles haue their vse; for some say they distend the passage as *Vesalius*, others as *Palopius* and *Archangelus*, that in the end of miction they expresse or driue out the reliques of the vrine which remained in the end of the necke of the bladder. But if they worke all foure together, they draw the root of the yarde, which as well as the body thereof hath a power or faculty of erection.

A caueas for
Chirurgions.

The vessels of
the yarde.
Veines.

Betweene these muscles in the *Peritoneum* [tab. 4. Figure 1, betweene M and H] or distance betweene the Cod and the Fundament are the stones of the Bladder taken forth. They call the place also *inter-feminium*, and in it Fistules and other vlcers are very ordinary. I saw a Knight of Lincolnshire of good place suddenly perish within few dayes of a gangrene new risen in this place, & it was credibly told me that his Father a Knight likewise, about the same age of his life was in the same place taken sodainely after the same manner and so perished. Wherefore this place is diligently to be considered of before a Chyrurgion worke vpon it.

The vessels that come to this virile Member are of 2. sorts, some outward others inward. The outward veines and arteries [table 8. Lib. 3. 11] arise from the veine and arterie called *Pudenda*, and are distributed through the skin. They are many and sometimes blackish like vnto bodden, bursten or varicous vessels.

The internall veines are double, and spring from the veine called *Hypogastrica* [table 8. lib. 3. 11.] These when they come vnto the middle bifurcation at the Crotch, doe almost alwayes vnite into one, which is carried along the body of the member in the middest among the arteries. From this veine a notable branch atteyneth into the capacity or cauitie of the *Abdomen*, and is disseminated through a Ligament which tyeth the bladder to the share-bones.

Arteries:

Vesalius?
Columbus?
Archangelus?

Bauhine con-
siste:

In like manner two internall Arteries and those very notable are inserted into the bodies of the yarde, from the Artery called *Hypogastrica* [table 8, lib. 3, 11] at the beginning of the Bifurcation of the same. The inuention of these arteries *Vesalius* attributeth vnto himselfe, as also the demonstration of their vse, whome *Columbus* taxeth; but *Archangelus* auoucheth that all the three sortes of vesselles in the yarde are so conspicuous that hee that is halfe blinde may see them; for being nourished, sayeth hee, why should it not haue veines as well as other parts; liuing why should it not haue Arteries, and mouing why should it not haue Nerues? *Bauhine* is of another minde, to wit, that the arteries are the vehicles of his nourishment which is thicke blood, and that the same arteries doe also deriue vnto it the mouing faculty, but of that more hereafter. We will return. Betweene the forenamed arteries in the middest passeth a veine through the backe of the yarde euen to the Nutte or glans, where it is implicated or foulded together with a nerue (which haply make the substance of

of the Nut fungous) all which conuey bloud and spirits into the spongy substance of the yard when it is prouoked or chafed.

It hath also Nerues so notable saith *Falopius*, that he that hath but halfe an eye may se the; *Galen* also in his 14. book *de vsu partium* and the 13. Chap. taketh knowledge of them. They proceede from the marrow of the great or holy bone, of which some that are cutaneous doe passe into the skin of the yard & the Testicles, to make them sensible of outward iniuries; others are inward, on each side one and that very notable, which ascendeth vnder the share-bone through the middle bifurcation to the coate of the yard, and from thence runneth diuersly disperfed to his muscles & to his whole body, together with the arteries through his back, as farre as to the Nut or glans, to giue it a more exact sence, especially the Nut where it is of most vse to stirre vp pleasure in the act of generation. In these Nerues hapneth that tumor which we call *ganglia*, that is a knotty tumor of a sinew resisting the finger that presseth it, yet not dolorous, which *ganglia* here are the cause that when the yard is erected itisse like a Rams horne as *Falopius* speaketh, it is not distended beyond his ordinary magnitude, but onely groweth full and turgid.

His nerues.
Falopius.
Galen.

Ganglia what
they are.

Finally, the vpper part of the yard is carnos or fleshy [Table 4. fig. 1, 2, 3, 4, 5, 7, 9. D] and looketh alwayes as if it were swollen; and indeede it hath a greater compasse then any part of the whole trunk (as *Archangelus* calleth it,) of his body, that like the bottome of a glasse Stil or cupping glasse, it might gather more heate vnto it selfe then any other part. It is equall, smooth, and turbinated, that is, broad at the basis or bottom, and growing smaller yet keeping his roundnes even to the top, much like a Turkes cap or turbant, and it is called glans or the Nut of the yard, and it is girt with a circle like a crowne. It is very soft that it might not offend the womb, somewhat acuminated or sharpned also at the top the better to fit it for the orifice of the matrixe; of exquisite sence it is, that in the attrition and motion, together with the intention of the imagination (which is most powerfull in both sexes in the matter of procreation) the seede might be more plentifully eiacted.

The glans or
nut of the
yard.

His figure.

Substance:

It is couered with a fine membrane, produced from that membrane which we said before did encompassse the pipe or Canale; and it groweth not vnlike to a mushrum vpon the heads of the two bodies of the yard. It is as we sayed of a spongy substance, which yet is not hollow within, but somewhat more solid and firme then other ordinary spongy bodies.

His membrane.

But that it might be kept smooth, soft and glib, it hath a couering which ariseth from the skin of the yard brought forward, and againe reflected or returned, which the Gracians call *proth*, *Galen* in his 15. book of the *use of Parts* calleth it *Cutis epiphysa*, in Latin *praputium*, we call it the *fore-skin*; that part which hangeth ouer the end is called *apophysis*, because in coition it is mooued vp and downe, that in this attrition it might gather more heate and increase the pleasure of the other sexe. Some say it was ordained for ornament also, and not without good reason, because vpon the more dishonest part, God & Nature, or rather the God of Nature, hath put the more honour, that is, the more couering.

The prepuce
or foreskin.

This *fore-skinne* in the end of it is sometimes so contracted or drawn together, that it cannot be drawne backe, nor the Nut discovered without the helpe of a Chirurgion. But when the Nut is vncovered, that it may recouer his couer againe, this prepuce is tyed in the lower part with a membranous band or tie, which the Greeks call *χαλινόν* some *κώρυ* and *κυνόδεσμον*, *vinculum caninum*, the Latines *frenum*, in English the bridle. *Archangelus* calleth it a Ligament, others will haue it to be made of the extremities or ends of the sinews, and this is it which bridleth or reyneth vp the fore-skinne on the lower side to the toppe of the Nut. It also furthereth the profusion of seede, communicating by the Canale motion and heate to the prostate glandules which containe the seede ready for eiactation. For oftentimes in lustfull disports or imaginations, if this bridle be but lightly moued the seede will incontinently issue forth; even as after a full meale, if a man but touch the end of his throate with his finger, the stomach by reason of the continuity of the parts, contracteth it selfe and returneth the *crapula* or vndigested gobbets into the lap by vomit.

In the midst of this Nut is a passage or hole through which both the seede and the vrine is powred forth, for it compasseth the common Canale at which place it is larger but presently is contracted againe, that the seede hauing there a kinde of momentary stay or stop, might procure more pleasure in this part. Wherefore those that labour of the *gonorrhoea* caused by the acrimony of rotten seed heaped vp in this large place, are here tortured with vlcers.

The vse of the yard is as hath beene saide in the particular parts thereof; only we will add, that

The vse of it,

that

that the auoiding of vrine was not the cause of the making of this member: (For we see women make water without it) but for procreation. Euen as Nature hath ordained the nose for smelling, yet she vseth it secundarily for purging the mucous excrements of the braine. So vpon a second intention this member serueth to deriue away the vrine wherewith otherwise we should lightly defile our selues.

And thus much shall suffice for the parts of Generation in men, wherein I haue bin indeed as particular as the Anatomical History did require, but yet withall hope I shal finde pardon, because the Reader may perceiue (at least if he haue any knowledge) that I haue pretermitted many secrets of Nature, which I could and would heere haue somewhat insisted vpon, if I had imagined that al into whose hands this work should come had bin competent and fit auditors for such kinde of Philosophy.

CHAP. IX.

Of the proportion of these parts both in Men and women.

The same parts of generation in men and Women.

Virgil. 1. Geor.

The wonderful prouidence and wisdom of God.

To bring a kind of eternity out of imperfection.

The particular parts of generation in Women.

Galen. The wombe is like the scrotum.

The neck of the wombe like the virile member.

The cause of the procreation of a woman.

It was the opinion of Galen in his 14. book *de vsu partium*, and the 11. chap. that women had all those parts belonging to Generation which men haue, although in these they appeare outward at the *Peritonaeum* or *interfemininum*, in those they are for want of heate retained within; for seeing a woman is begotten of a man, & perfect also in makind (for natures imperfections are not so ordinary) it is reasonable that the substance, yea and the shape of the parts in both sexes should be alike, as comming from one and the same set as it were of causes. Neither is it so vncommon in Nature, that those parts which in some creatures are prominent and apparent, should in others be veiled and couered: for Moles indeede are not without eyes, but haue them lying deeper in their heads & ouerco- uered, whence Virgil saith, *Aut oculis capti fodere cubilia calpe,* that is;

Or hood-winkt Moles haue dig'd their Bowers.

So we call captiues, not those which are not at al, but which are in restraint or in bands. Although heerein Nature hath excellently acquitted her selfe, that the abatement of naturall heate, which in men is the onely naturall and necessary cause of their dissolution, should so admirably become in women the originall of generation, whereby wee should attaine a kinde of eternity euen of our bodies, against the destined corruption of the matter, arising from an importunate discord of contraries. For so it pleased the Diuine Wisedome to create for the eternall soule (the most excellent of al formes) if not an eternall habitation heere, yet so absolute & admirable a structure, as might so long be perpetuated below, till it come to be eternized aboue after an ineffable manner of recreation.

Wherefore to return. In this other sexe, there are some parts which bring down the matter of seede out of the whole body, to wit, the spermaticall veins and arteries; others worke & labour it into good seede, as the body called *Varicosum* and the testicles; others leade the perfected seede, called as in men *vasa deferentia* or leading vessels. Lastly, the womb or Matrixe which receiue the seede together with the mans, retaineth it, and worketh vpon it for the generation and preservation of mankind. This womb is likened by Galen in his 4. book *de vsu partium*, and the 6. chap. to the *scrotum* or cod of a man [tab. 11. fig. 1.] as if the cod were but a womb turned the inside outward, and hanging forth from the Share-bone; and *Archangelus* maketh no other difference betweene them but of scite and insertion. For if a man doe imagine the cod to bee turned and thrust inward, betwixt the bladder and the right gut, then the testicles which were in it will now cleaue to it outwardly on either side, and so that which was before a cod will now be a perfect Matrixe.

Againe, the necke of the wombe (saith he) is in stead of the yard, for they are both of a length, and by friction and refraction the seede is called out of the like parts, into the same passage, onely they differ in scituation which is outward in men, inward in women. *Fallopins* frameth the comparison of the parts somewhat after another sort, as we shall see heereafter when we come to the Controuersies.

So then, in the first conception or soone after, whether it be in a man or woman, the same Members are generated, but the fruite prooueth male or female, because of the temper of the seede and the parts of generation, either by heat thrust out, or for want or weakenes of the heate retained within: wherefore a woman is so much lesse perfect then a man by how much her heate is lesse and weaker then his; yet as I saide is this imperfection turned vnto perfection, because without the woman, mankind could not haue beene perfected by the per-

ZZ. The two vmbilicall Arteries.

perfecter sexe. The great Maister workman therefore of set purpose, made the one halfe of mankind imperfect for the instauration of the whole kind, making the woman as a receptacle of the seede of which a new man was to be created. We haue therfore in this 5. Table exhibited the lower belly of a Woman, and remooued the guts that all thinges might bee more conspicuous; but now let vs come to the particular parts in a woman, beginning first with the spermaticall vessels.

CHAP. X.

Of the preparing Spermaticall vessels.

THe Spermaticall vessels which bring the seede from the whole body, and prepare it for further vse, are foure: Two Veines, & two Arteries. *Galen* in his book *de disse-*
ctione vteri, maketh mention of foure other vessels obserued by *Herophylus* in some women, which arise (saith he) from those vessels which go vnto the kidneies, and so passe in-
 to the womb, which saith *Galen* I could neuer finde in any creature, but onely in Apes. The
 right vein buddeth out of the [tab. 6. ad] trunk of the hollow vein below the emulgent, neere
 the great or holy bone; the left proceedeth [tab. 6. ee] from the left emulgent, because on this
 side the great Artery is scituated neere the hollow veine, which artery mooueth or bea-
 teth continually, so that if this left spermaticall vessel had proceeded out of the trunk of the
 hollow vein, it must of necessity haue bin carried ouer the great artery, & then this thin vein
 had bin in continuall danger of breaking by the incessant motion of the Artery.
 But both the Arteries [tab. 6. gb] arise from the trunk of the great Artery vnder the emul-
 gent neere the great bone, and are full of sprightfull blood. *Galen* recordeth, that *Aristotle* &
Erasistratus thought they contained nothing but spirits, with whom *Bonacciolus* & *Mercatus*
 seeme to consent. And although these haue the same originall with the arteries of a man,
 yet do they not, as in men, fal out of the *Peritonaeum*, neither reach vnto the share-bones (for
 it was not needfull that women as men should cast their seede out of themselves, but onely
 into their matrix) neither are they mingled together, or grow one into another before they
 come vnto the testicles, although *Vesalius* would haue it so. Wherefore they vary in their in-
 sertion and diuision. For in women they are supported with fat membranes [tab. 7. fig. 1. EE]
 and so are carried to the testicles [tab. 6. ii; tab. 2. fig. 1. F] but before they come there, after
 an inoculation or Anastomosis made between the veine and the artery, they are diuided

ry small.

saith *Galen* in his 14. book *de vsu partium* and chap. 9. into 2. parts; one part maketh the se-
minary vessell [tab. 7. fig. 1. *IK*] and the *corpus varicosum*, communicating to the testicles and
their coat certaine small branches for their nourishment.

The other part reacheth to the membrane cleauing to the bottom of the womb, [tab. 6. *ll*,
tab. 7. *H*, fig. 1. fig. 2. ff, fig. 3. *bb*] and so is distributed into the sides of the matrix, and carrieth
nourishment especially to the vpper part of the bottome or soale of it; as also for the nour-
ishment of the conception, that it may be fitly cherished with laudable blood; by which ves-
sels also a part of the mensuall courses especially in women; but not with child, is purged,
but in men these vessels are all consumed into the *corpus varicosum*.

They differ also from mens vessels in the shortnes of their course or way: for because the
seede of the women stood not in neede of so great elaboration as the mans did, therefore
there was no necessary vse of the same length; beside if they had been so long they could not
haue beene contained within the belly. These vessels being enfoulded and enwrapped one
within another by an admirable Anastomosis or inoculation for the *delineation or perfection*
of the seed, make (saith *Galen* in his 14. book *de vsu partium* the 14. chapter) if any, yet very
small *parastate* and scarcely discerned, because the Testicles themselues are small and the
spermatieall vessels small also: *Archangelus* saith that from these vessels goe vnto the Te-
sticles certaine small branches.

CHAP. XI.

Of the Testicles.

The Testicles which because of the in-bred coldnes of women are included within
the lower venter [tab. 5. *MN*, tab. 6. *ll*, tab. 7. fig. 2. *ii*, fig. 3. *ff*] that they might bee
kept warme and bee made fruitfull, doe lye one on either side at the sides of the

Table 6. sheweth the lower Belly the Guts being taken away, as also the Stomacke, the Mesentery, and some
Membranes, that the vessels seruing for generation may the better bee discerned. Also the Breast or Dug of a
woman excoriated, is here exhibited.

The vse of a
womans testi-
cles.

They differ also in magnitude for they are much lesse in substance, because they are moi-ster and softer, yet *Vesalius* thinks they are harder then in men. Neither is their substance so compact, because they were to ingender a more imperfect seede. In Temperament they are colder, whence womens seed is more moyst, thinne and waterish. Imagine, that of this thinnes as it were of water, and of the seede of the man which is thicker as it were of flower a certaine paste is made and in the wombe fermentated or wrought vp into the forme of a man; or because *Hippocrates* sayth that man consisteth of water and fire, we may say that the seede of the women is the water, and that of the man the fire, because as the fire it carrieth in a small body or matter, a great deale of actiuitie or forme; although I am not ignorant that this of *Hippocrates* is and may bee otherwise taken, as that both the seeds are the water, and the spirit is the fire; which Nature by the helpe of an aduentitious heate doth extract and segregate from the more excellent part of the seed, especially of the man, lying before hid in the power or possibility of the matter, which is called by Scholers *potentia materia*, which spirit assisted by the formative faculty of the wombe, doth with a discerning iudgement deduce and distinguish into proper acts the power or possibility of the parts mixed together confusedly in the masse of seed. This spirit also moueth & illumineth al the parts and moderateth all the actions of mans life, of which it is also chiefe cause. And therefore it is that we say, that the seed of a man is the actiue principle of the body, that of women but the passiue, or at least far lesse actiue then the other. But if the seed of both sexes had beene thicke, glewy & compact, they could not haue beene so perfectly mingled. Finally, they differ in their coats or coverings, for they haue but one, [tab. 7. fig. 1. K] because being conteyned in a hidden and safe place they needed no more: that coate *Galen* calleth *dartos*, and it is thinner & softer then that in men, but cleaueth to the testicles very strongly, as if it were one body with them. This coat also receiue the vessels of seed, & inuesting their substance containeth it or holdeth it in. The productions also of the *Peritoneum* doe incompasse only the middle part of the testicles where they receiue the spermaticall vessels.

The vse of the testicles, as say *Columbus*, *Archangelus*, *Laurentius* and *Baubine*, is by their inbred power to make the seed fruitfull. *Falopius* is not of this mind, *Platerus* halteth betwixt both; but we know assuredly that those women whose testicles are ill disposed are barren & vnfruitfull: for women as well as men do yeeld seed, but cold, though *Aristotle* deny it in his first book *de gener. Animal.* and the 20. chapter, who would haue that humour which is auoided by the neck of the matrix not to be a seminary or feedy humor, but a proper humor of the place, to wit an excrement of the womb, which also should be found in some, but not in others; as especially browne or swart coloured and mannish women. But *Hippocrates* in his 1. book *de diata*, and in his book *de natura pueri*; & *Galen* in his 14. book of the *vse of parts* and the 11. Chap. haue taught, that to perfect generation there is required a concurrence and mixture of the seeds of both sexes; and a place wherein (the forme of the parts being onely in power present,) the seede might be brought into act, such is the wombe; of which we shall heare by and by.

CHAP. XII.

Of the vasa deferentia or Leading vessels.

Laurentius &
a Castro
Pinaus

He vessell which leadeth the seede is on either side one [Table 6. mm. tab. 7. fig. 1.*, fig. 2. gg. fig. 3. gg] which Laurentius and Rodoricus a Castro would haue to arise from the preparing vessels, Pinaus from the Testicles. It is said to be sustained by the Li-

The first Figure sheweth the wombe cut from the body, with the vessels which grow vnto it, the Testicles, the Bladder and the Membranes: the necke of it is turned upward, that the orifice of the bottome of the wombe may the better be perceived: the bladder also is opened, that his cavity and the insertion of the Vreters may better appeare.

The 2. Figure sheweth the wombe with his vessels parted from the Membranes and the Bladder.

The 3. Figure sheweth the wombe freed from all the vessels excepting the spermaticall vessels, where also the forme of the Trumpet is omitted.

The 4. Figure sheweth the womb cut out of the body, & the thickness of his coates in a woman with childe; and the cleft of the lap or priuity dilated or laide open.

The first Figure.

- A, The bottome of the wombe laide open without any Membrane.
- BB, The necke of the wombe turned vpward.
- CD, A part of the bottome of the wombe like the nut of the yard, swelling into the vpper part of the necke of the wombe, in the middle whereof the orifice appeareth.
- EE, A Membrane knitting the wombe to the Peritonaeum, and holding together the vessels thereof.
- F, The left testicle.
- G, The spermaticall veine and artery.
- H, A part of the spermaticall vessels reaching vnto the bottome of the wombe.
- I, One part of the vessels comming to the testicle.
- K, A vessell leading the seede vnto the wombe.
- L, The coate of the testicle with the implicatio of the vessels.
- M, The cavity of the Bladder opened.
- N, The insertion of the Vreters into the Bladder.
- O, The Vreters cut from the Kidneyes.
- P, The insertion of the necke of the bladder into the lap or priuity.

The second Figure.

- aa, The spermaticall Veine and Artery.
- bb, Branches distributed to the Peritonaeum from the spermaticall vessels.
- c, The bottome of the wombe.
- d, The necke of the wombe.
- e, Certaine vessels running through the inside of the womb, and the necke thereof.
- ff, Vessels reaching to the bottome of the wombe produced from the spermaticall vessell.
- gg, The leading vessell of seede called Tube the Trumpet.
- hh, A branch of the spermaticall vessell compassing the Trumpet.
- ii, The Testicles.
- kk, The lower Ligaments of the wombe, which some call the Cremasteres or hanging Muscles of the wombe.
- l, The lap or priuity into which the Cremasteres do end.
- m, A portion of the necke of the bladder.

The third Figure.

- aa, The spermaticall vessels.
- bb, A branch from these spermaticall vessels to the bottome of the wombe.
- cc, The body or bottome of the wombe.
- d, The necke of the same.
- e, The necke of the bladder ending into the necke of the wombe.
- ff, The testicles.
- gg, The leading vessels, commonly though not so well called the ejaculatory vessels.
- hh, The diuision of these vessels, one of them determining into the hornes at double kk.
- ii, The other branch ending in the necke, by which women with childe auoide their seede.
- kk, The hornes of the wombe.

The fourth Figure.

- AB, The bosome of the bottome of the wombe, at whose sides are the hornes.
- CD, A line like a suture or seame, a little distinguishing that bosome.
- EE, The substance of the bottome of the womb, or the thickness of his inward coate.
- F, A protuberation or swelling of the wombe in the middle of the bosome.
- G, The Orifice of the bottome of the wombe.
- HH, The coate or second couer of the bottome of the womb, comming from the Peritonaeum.
- III, A portion of the Membranes which tie the wombe.
- KK, The beginning of the necke of the wombe.
- L, The necke of the Bladder inserted into the necke of the wombe.
- m, The Clitoris in the toppe of the priuity.
- n, The inequality of the priuity where the Hymen is placed.
- o, The hole or passage of the priuity in the cleft.
- p, The skinny caruncle of the priuity.

L, The necke of the Bladder inserted into the necke of the wombe. m, The Clitoris in the toppe of the priuity. n, The inequality of the priuity where the Hymen is placed. o, The hole or passage of the priuity in the cleft. p, The skinny caruncle of the priuity.

gament of the wombe, as it were with a prop. Neruous it is and white, about the Testicle broad and large, [tab. 6. mm, tab. 7. fig. 1. * fig. 2. gg] (saith *Galen* in the 9. chap. of his Book *de dissectione uteri*.) membranous also, and a little complicated or folded like a small seminary bladder being rugous, such as in men is at the *prostate*. In the middle it hath a notable hole or passage like the mouth of a trumpet, whence *Falopius* calleth it the Trumpet of the womb, and saith it is found not onely in the bodies of women, but also of all female creatures, by which as by a breathing vent the smoky vapors of the womb do exhale into the capacity of the *Abdomen*; and this hole the spermatike vessels do compasse, [Tab. 6. n. 1, tab. 7. fig. 2. hh] and it is curled vp after the maner of a Vine tendril. For it is more rugous [tab. 7. fig. 3. gg] & fuller of windinges then it is in men, and that because of the shortnesse of the way, which is recompensed by the multitude of turnings, seing it could not passe through the production of the *Peritoneum*, because the Testicles did not hang out.

tion.
Falopius.

These Leading vessels hauing passed the Testicles a little, become by degrees narrower, [tab. 6. mm, tab. 7. fig. 1. * fig. 2. gg] and are not carried as in men to the necke of the bladder, but to the wombe; and when they come to the sides of it, [tab. 7. fig. 3. kk] which are called the hornes of the wombe (from whence *Falopius* and *Platerus* think these leading vessels do issue) they are diuided on either side, [tab. 7. fig. 3. hh] and one part which is the shorter and larger, is implanted into the middle [tab. 7. fig. 3. k] of the horne of his own side, or neere vnto it; and powreth into it and into the hollownesse of the womb, seed perfectly boiled, but the other part which is narrower but longer [tab. 7. fig. 3. ii] is carried along the sides of the womb to his necke [tab. 7. fig. 3. d] on either side, and is inserted below the innermost mouth vnder the necke into the *Prostate*; which are not so conspicuous as they are in men, because the seede of a woman is not so corpulent or beareth not such a bulke. These keepe the seed till the time of coition, and by this way women with child in accompanying with men do loose seede, and not by the inmost mouth of the wombe opened. For whereas after conception the mouth of the wombe is exquisitely closed vp, [tab. 7. fig. 1. betweene C and D, and fig. 4. G] and yet euen then women in coition do loose seede; it is necessary the same should passe some other way, because the cavity of the wombe being on euery side filled, the seede that should come from the bottome or side of it cannot haue recourse vnto the orifice, or if it could, yet seeing that is so straightly stopped & must not be reclud or opened for feare of abortment, it would follow that the seed putrifying the Infant should perish. For seede when it is out of the vessels, cannot without great danger be retained, yea it becommeth very poyson, as *Galen* saith in his 6. Book *de locis affectis*, and the 5. Chapter, and we also may plainly see in the greuous fits of widdowes troubled with the Mother; wherefore this passage [tab. 7. fig. 3. ii] as *Varolius* rightly admonisheth must be in the neck of the womb, which in those that haue not conceiued is so small, that it cannot be perceiued vnlesse the Anatomist be very diligent and oculte: but in women with childe it is very large and manifest. Hence it is, that many women when they are with child, conceiue greater pleasure in their husbands then at other times, and also some women more then others. But *Falopius* is of opinion, that these Leading vessels doe arise from the sides [tab. 7. fig. 2. g] or hornes of the womb, & are caried vpward obliquely by the testicles but do not arise from them, because in sound and haile women they are distant from the testicles the bredth of a finger, neither that there appeareth any vessell which passeth from the testicles to these holes or passages, but are onely coupled together by a thin membrane produced from the *Peritoneum*, but do not so much as touch one another. But if the wombe be euill affected and that on one side, then the leading vessel is ioyned to the testicle on the ill affected side, but not on the sound; but if both sides of the wombe bee affected, then both the Leading vessels are ioyned with both the testicles.

CHAP. XIII.

Of the Wombe or Matrixe.

He wombe called *Vterus*, is by *Aristotle* called the Field of Nature, into which the seede as well of the woman as of the man, is partly powred partly drawne, to which accrueth the womans blood, that the new off-spring of mankind might bee ingendred, nourished, encreased, and kept to the due time of birth. For the

Naturall

The forming
Faculty.

How all the
parts are for-
med at once.

The names of
the wombe.

The situati-
on & the rea-
sons thereof.

Naturall and vegetable soule which lyeth potentially in the seed, diffused equally through the whole masse, must be produced into act; and it is so produced by the vertue and heat of the wombe that receiued the seede, and the forming faculty which potentially consisteth partly in the seed of man, partly in the nature of the womb, and is called *vis plastica*, and so of both seeds mingled are framed and procreated equally together and at one and the same time all the parts of the body, but you must vnderstand their Spermaticall foundations and solid substance; as for their sanguine foundations or proper *Parenchymata*, they are procreated at diuers times, as they sooner or later get nourishment and fire, that is, spirit; and so those parts that are neerer to the Liuer are perfected before those that are more remote, and those first into which first the mothers blood doth flow, that is, first the vmbilicall vein, wherefore that is first absolued in his fleshy substance, from which afterwards the blood is led and conuayed into other parts.

It is called *Vterus* properly in women, because it is hollow like a bottle, and as a bottle or bagge of leather is filled and distended with the Infant contained in it; *Hippocrates* calles it *γυνή*; but most commonly the *Gracians* call it *ύστέρα*, because it hath the last place among the entralles or inwards; also *μύτρα*, *mater*, or the mother, because it is the mother of the Infant, some call it *vulua*, but that is properly in Beasts, as *Pliny* witneseth in the 37. chap. of his 11. Booke; it is called *locus* or rather *loci*, the place of a woman.

It is placed within the body [Table 5, L, tab. 8. p. tab. 10. L] because the seede after it is cast into the wombe, needed much heat to stirre it vp and to mooue it toward the delineation of the parts. In the lower belly (not in the middle or supream, for that these two are compassed with bones and cannot bee dilated according to the increase of the Infant, but would haue stifled it by compression;) because this is easily dilated as the burthen increaseth, and in the lower part of it called the watercourse or *Hypogastrium*, partly because it should bee no hinderance to the nutritiue parts, partly for the more commodious begetting and

Table 8. sheweth the lower Belly the Guts being taken away, as also the Stomacke, the Mesentery, and some Membranes, that the vessels seruing for generation may the better bee discerned. Also the Breast or Dug of a woman excoriated, is here exhibited.

TABVLA VIII.

- A, B, C, D, The *Peritonaeum* reflected or returned backward, above & below.
E, F, The gibbous part of the Liuer E, the caue or hollow part F.
G, The trunk of the gate veine.
H, The hollow veine.
I, The great artery.
K, The roots of the *Coliacall* artery which accompanieth the gate veine.
L, M, the fatty veine going to the coat of the kidneies.
N, O, The fore-part of both the kidneies.
T, V, The emulgent veines and arteries.
aa, The right vreter at the lowest A, cut from a part which neere to b, sticketh yet to the Bladder, because the bottome of the Bladder is drawne to the left side.
c, The left vreter inferred in to the Bladder neere to r.
dd, The spermaticke veine which goeth to the left testicle marked with s.
ee, The spermaticke veine which goeth to the left testicle marked with i, also.
f, The trunk of the great artery from whence the spermaticall arteries do proceed.
g, h, The spermaticall arteries.
ii, The two testicles.
k, A branch which from the spermaticke vessels reacheth vnto the bottome of the wombe.
mm, The leading vessell of the seed which *Falopius* calleth the *tuba* or trumpet, because it is crooked and reflected.
n, A branch of the spermaticke vessell compassing the leading vessell.
oo, A vessell like to a worm which passeth to the wombe, some call it *Cremafter*.
p, The bottome of the wombe called *fundus Vteri*.
q, A part of the right gut.
r, s, The bottome of the Bladder whereto is inserted the left vreter, and a veine led from the necke of the wombe neere vnto r.
t, The necke of the Bladder.
u, The same inserted into the priuity or lap.
x, A part of the necke of the wombe about the priuity.
yy, Certaine skinnie Caruncles of the priuities in the midst of which is the slit, and on both sides appeare little hillocks.
- The Figures belonging to the Dugs or Breast.
- aa, The veins of the Dugs which come from those, which descending from the top of the shoulder, are offered to the skin.
β, The veins of the Dugs deriued from those which through the arme-holes are led into the hand.
γ, The body of the Dug or Breast.
δ, The kernels and fat betweene them.
ee, The vessels of the Dugs descending from the lower part of the necke called *ingulum*, vnder the Breast bone.

bring-

bringing forth of the fruit. The den or cavity of the body wherein it is contained is called *Pelvis*, that is, the labour or bason; so that it is compassed about as with strong rampires for defence, with the share-bones before, the great bone behinde, and the hanch bones on either side. I speake of the wombe vnburdened, for then the bottome of it reacheth not higher then the beginning of the great bone, neither toucheth it anything but the right gut, [Tab. 5. K. Tab. 8. q.] vpon which it lieth, nor reacheth forward about the bladder; [tab. 5. 2, tab. 8. f] for it is placed betweene the bladder and the right gut, that backward it might haue, as it were, a pillow (saith *Galen* in the first chap. of his Book *de dissectione uteri*, and in the 14. Book *de usu partium* and the 14. chap.) betweene it and the backebone, that it might not be hurt by his hardnesse, and before it a strong membrane, to wit, the bladder as a bulwarke to defend it. Here we may see the glory of the ancient habitation or mansion house of mankinde, how that we are bred of a brittle and perishing substance betweene the excrements and the vrine, and must moulder againe into earth and dust, wherefore in the ruffe of our pride let vs seriously consider of that saying of *Pliny*, *Alas, how soittislye franticke is he, that imagines himselfe out of so meane and base beginnings, to bee borne to pride; but to returne to our History.*

The wombe is placed in the midst of the neather belly, that the body might bee equally ballanced, saith *Galen*, & for that cause the lauer or basen is larger in women, from whence also they haue larger buttockes then men.

But as the burthen increaseth, the womb in the vpper part (which is the bottome) being loose and at liberty groweth vpward to the nauill [tab. 10. l] & leaneth vpon the small guts, yea and fulfilleth al the places of the flaukes when they are neere the time of their deliuerance. Neither then doth it so directly keepe the middle place of the belly, but leaneth either to the right hand or to the left, according to the diuersity of the sexe of the infant, although this be not perpetuall. Sometimes there falleth some part of the kall betweene the bladder and the womb, and there causeth barrennes by the compression of the mouth of the womb, as *Hippocrates* conceited and expresseth in the 46. Aphorisme of the 5. section. It is knit partly by the very substance of it, partly by foure ligaments, whereof two are aboue, two bellow; but the bottom [table 8. p] before, behinde and aboue is adioyned to none of the adherent parts, but is loose, free and at liberty, that it might better be distended in women with child, and in coition when the desire of conception is, might more freely moue, now vpward then downward & open it selfe to the end of the yard, whence *Plato* in *Timaeo* calleth it *ζῷον ἀνιθρομνικόν*, that is, a crawling creature (so saith *Salomon*, *The barren womb neuer saith it is enough*), because in the conception it hath a kinde of Animal motion or lust to be satisfied; neither doth it onely moue it selfe in the lust of conception, but also it wil in a manner descend or arise vnto any sweete smell, and from any thing that is noysome: which is the reason that many women are so easily offended with the smell of muske or other perfumes taken at the nose, for that the wombe moueth vpward vnto them; and in the fit of the rising of the mother, we apply burnt feathers and such like noysome vapours to the nose to driue the wombe downward againe, as also sweete and odoriferous suffumigations below to draw it downward to the owne naturall seate.

At the sides it is tyed to the haunch bones by membranous ligaments [tab. 5. 00 20. tab. 10. l K. tab. 9. fig. 4 III] arising as *Galen* saith in his 4. Book *de usu partium*, and cap. 14. & in the 4. cap. of his book *de dissectione uteri*, from the Muscles of the loines; but we rather think (saith *Banbime*) from the *Peritoneum*, and may be compared to Bats wings [tab. 9. fig. 1. EE] These Ligaments are woven sometimes with fleshy Fibres (whereupon *Vesalius* and *Archangelus* haue named them Muscles) by whose helpe they being distributed into either part of it, the wombe is held stedfast. These Ligaments although they bee strong, yet are they some-what loose or laxe and softe, so that in no part there are found so laxe ligaments, the reason is, that they might better be extended with the wombe, and follow it also in the motions without dilaceration; for the wombe when it is filled is large and wide, but afterward is contracted into the quantity of a Peare or a halfe-peny purse.

These Ligaments also, as *Hippocrates* and *Plato* in *Timaeo* haue written, like to Bridles do hold in the wombe, which yet notwithstanding rideth as a moored Ship in a Tempest betweene her Anchors, especially in barren women, sometimes vpward to the Liuer and Midriffe, and compressing them it bringeth a feare of suffocation; sometimes downward, bearing toward the hips, and causeth in them great paine, but especially it troubleth the left side, whence it is that we obserue that those women which beare vnprofitable burthens

somewhat musculous and so subiect to some distention) and if it descendeth any thing at all it is but a very little; but when it is drawne vppward to the bottome of the stomack, that hapneth by reason of the conuulsion of the vessels, which is sometimes from repletion, sometimes inanition; not that the wombe is a living creature or hath voluntary motion, or ariseth it selfe about the stomacke.

So haue we seene in a generall, or by and by after a generall conuulsion of the whole body, those vessels so conuelled that the wombe hath pressed vppon the parts next vnto it, those vpon the midriffe, the midriffe vppon the lungs, the lungs vpon euen to the throate; so that some haue thought the partie to bee possessed of the foule fiend; some that would make themselues wiser, and should by right haue had more wit, haue sayd that the mother rose into the throate. But *Hippocrates* in his Booke *de articulis*, hit the nayle right when hee sayd; that the wombe of it selfe changeth not much his place, but is drawne by other parts. Yet sometimes what with the waight of the Infant, what with the difficulty and violence of the birth, the ligaments are so relaxed that the bottome of the wombe falleth downward into the lappe: sometimes also the necke is turned and it hangeth forth of the priuities like a yarde betwixt their thighes, that it must be taken away by the Chyrurgion, or fall of it selfe when the ligaments are putrified, as we shal hereafter haply more particularly declare in our Treatise of the accidents of the wombe in a worke of Chyrurgery, which now gloweth and sparkleth vpon the anuile.

For it is not to be doubted (say diuerse both Greekes and Arabians; beside some experience also of our owne times) but that a woman may liue without a wombe, because there is no necessity of it for the preseruacion of the particular or indiuiduall nature, but onely for the propagation of the kinde.

The necke of the wombe is tyed to the neighbour parts but not round about; at the sides it groweth to certaine membranes, and by their mediation is loosely tyed to the *Peritoneum*; backward it fasteneth to the great or holy-bone, and to the right gut with very thinne fibres and a little fat on which it lyeth all along his passage, and aboue the lap groweth into one with the fundament to which it is before vnited; so that sometimes when the fundament is vlcerated a little within, the excrements haue beene seene to fall out at the lappe. Before, it is tyed to the necke of the Bladder. [tab. 8. 1. tab. 9. fig. 1. O. fig. 4. L.] And because the neck of the womb is broder, part of it is tyed to the share-bones by the help of membranes arising from the *Peritonæum*, hence it is that in inflamations of the womb there followeth a *Tenesmus*, (which is a vaine desire or dolorous offer to the stoole,) and the strangury: and so much of the vpper ligaments of the wombe.

The lower Ligaments of the womb [tab. 8. 2. tab. 9. fig. 2. K.] of which *Vesalius* maketh no mention, are likewise two, which *Laurentius* calls *xpuaσnres*, *Columbus*, *processus uteri*; *Varolius*, the hornes of the womb: but indeede they are certaine neruous productions, round like to earth wormes, reddish, and hollow especiallie in their end like vnto the husky-membrane, which cavity is sometimes found to be filled with fat. These ligaments proceed on either hand from the sides of the womb [tab. 8. at p. tab. 9. at c] and in their beginning or originall they touch the leading [tab. 8. mo. tab. 9. fig. 2. g] vessels of the seede; thence they rise vnto the lesk, and are carried through the production of the *Peritoneum*, as the spermatike vessels of men, and passe through the Tendons of the oblique Muscles of the *Abdomen*. This production being dilated, when also the inward coate whereof it consisteth is first broken (as in hard bargaines of trauell it often hapneth) there falleth to Women as to Men a rupture of which they are cured by Ligature after section. But section in Men is not to be vndertaken vnlesse they be willing to lose their Virility.

To these after they are out of the *Abdomen*, are ioyned fleshy fibres comming from the hanch-bones, which make certaine small muscles called *xpuaσnres*, in Latine *suspensores*, that is, *hangers up*, of which *Vesalius* maketh no mention. These in Women haue no communication with the Testicles, albeit in Men they haue, because they adioyne to the spermatike vessels.

These Ligaments aboue the share-bone [Table 9. Figure 2. I] do degenerate into a broad and finewy slendernes (mingled as it were with a Membrane which toucheth and inuesteth the fore-part of the share-bone) vpon which the *Clitoris* cleaueth and is tyed; in so much that being Neruous and therefore of most exquisite sense, from his attrition lustfull imaginations are communicated to these Ligaments, and from these to the vessels leading the seede: although their vse also is, to hold the wombe suspended least it fall out of the lappe (like

The Vses of the ligaments

(like as the *Cremasteres* in men doe suspend the Testicles) to strengthen and corroborate it, as well because of the great burthens it carries often and long, as of the strong throwes in the birth, and the humours which doe flow thither out of the whole body, which doe not onely moysten the part, but also might very well relaxe it. Finally by how much these Ligaments haue more fleshy fibres wouen into them, by so much do they (sayth *Pinaus*) more leane to the office of muscles, helping the voluntary attraction of mans seede out of the necke into the cauity of the wombe.

The Figure of the wombe.

The figure of the wombe is round [table 8. p. table 9. figure 1. A. figure 2. c.] that it might bee the more capacious, and lesse obnoxious to iniuries; aboue, it is somewhat depressed [table 9. figure 3.] like the bladder, excepting the tops of it which they call the hornes. For in women with child, as in the bladder so in the womb, the bottome is long and the necke narrow; but in those that be not with childe the bottome is no broader then the necke. *Soranus* and out of him *Falopius* likeneth it to a pressed cupping glasse, both for the forme and also for the manner of attraction; for the seede of man cannot attaine vnto the bottome of the wombe vnlesse it be drawne. Taking it together with the necke it is very well compared by *Archangelus*, *Laurentius*, *Pinaus*, and *Bauhine* to a Peare. [tab. 9. fig. 3.] For the bottome downeward directly from the corners becommeth narrower by degrees euen to the beginning of the necke, which is like a long and round passage, yet so as that the bottome

is of a figure most like vnto roundes as wee see in a good fayre Peare, whose bottome is round and bottle fashion.

The magnitude of it is not in all women alike, but differs according to the age, body, and impregnation or burthen. In Virgins that are growing it is smal and lesse then the Bladder; but in women grown it is greater; so in those that vse not mans helpe, and in old women because they are dried and withered, it is but little, (that it may the lesse trouble the neighbour parts) and thicke, not much broader then two fingers, and in length scarce euer so long as three (I meane the bottome,) seldome reaching about the share-bone and the Bladder. In full grown women it is greater, (yet those that haue neuer conceived are much like to virgins) because there is present vse of it; and after a woman hath bred in it, it remaineth during the strength and ability of their age somewhat larger then when shee was a growne Maid, yet not about a handfull. In a woman with child it is increased into all dimensions, for the larger it is stretched the thicker it groweth, which is one of the wonders of Nature. It hath two sorts of parts, simple and compound. The simple parts are the Ligaments of which we haue spoken; membranes, veines, arteries and nerues, of all which the wombe is compounded. The compound parts are foure, the bottome, the mouth, the necke and the lap or outward priuity. The membranes are two, one outward another inward, whose Nature and property it is to be able to be extended or stretched, and againe contracted and gathered together. The *uter* [tab. 9. fig. 4. membrane and is nervous, is the thickest of all membranes that come from the *Pertionum*: wherefore it is strong and growes to the wombe on both sides and is doubled, inuesting it for more safety and strength. The inner [Table 9. Figure 4. EE, table 11. figure 1. ABCD,] or proper is double, but yet so ioyned that they can hardly be distinguished but in exulcerations; betweene which as betweene the coates of the stomacke there are placed fleshy fibres; which they that say the wombe hath but one coate, doe not call a coate but the very substance of the wombe, when indeed both these and the outward make the substance of it together membranous, thight, and compact; that when the burthen is increased they may be dilated, and after the birth may be contracted again; but by reason of this inner or proper membrane it is fleshy or very thick that it might haue heate to cherish the seed and the Infant; and beside it is porous, that it may bee extended according to the increasing of the burthen. Wherefore it exceedeth in thicknes all other coates of the belly, neyther doth it alwayes keepe the same thicknesse saith *Galen* in the 8. Chapter of his Booke *de dissectione uteri*: for in youth it is small and also the thinner, but after the courses begin it growes in thicknesse as in magnitude, as also it decreaseth both in magnitude and thicknesse when Women leaue to conceyue and their courses stay. For the beginning and end of their courses is, when they begin and cease to be fit for conception. So when the time of the courses is at hand, it growes thick & somewhat tumified, as being watered or dewed with the humidity of the blood which floweth vnto it. Againe, the oftner a woman hath conceived the thicker it is.

 GG 2. The coniunction of the vmbilicall vessels as they are encompassed with their coate, resembling a gut.

Moreover,

Moreover, in the time of conception it is thicke and softer and growes thicker as the conception encreaseth, being thickest of all at the time of the birth. Yet *Galen* leemeth to say otherwise in his Booke *de dissectione uteri*, and the 8. chapter, and the 14. booke of *the use of Parts*, and 14. chapter (which opinion of his many follow) albeit it is against himselfe a little before where he sayth, that it groweth thicke when the courses come because of blood; now we know that the greater the Infant growes, the more blood accrueth vnto the wombe.

And indeed by dissection we are taught, that about the time of deliuerance and in the last moneth it becommeth two fingers bredths thicke, and that not onely in one place but every where, especially toward the higher part of the bottome or soale in which the vessels of the wombe did meete, and to which the after-birth called the *secundina* doe adhere; for as wee said before after the conception it encreaseth in all kinds of dimensions till it be vnburdened. For from the plentiful confluence of blood, because of the many veins & arteries scatteringly disperfed through his coates, his substance becomes fleshy, fungous, spongy, and diuisible into many shels or huskes like a Bezoar stone, or after the manner of mushrummes that it might containe the greater quantity of blood and spirits for the life and nourishment of the Infant, and beside the heate beeing encreased it necessarily draweth more vnto it, and so it tumifieth and is distended; but after the birth when the confluence ceaseth, it returneth to his

former

former both magnitude and thickeſſe. For if it neuer gathereth that carnoſity & ſoftneſſe the woman neuer conceiveth. But if it ſometimes do not gather it, then is ſhe for that time fruitleſſe, whence it is that we ſee ſome women which have conceived to become fruitleſſe for a ſpace, and after fall to bearing a freſh.

A cauſe of pleaſure.

The vein from the Hypogaſtrical.

Acetabula and Cotyledones what they are.

Betweene theſe Membranes run Fibres (ſaith *Galen* in his 14. Booke *De uſu partium*, and the 14. chapter) of all ſorts, becauſe it muſt draw and retaine the ſeede and expell the burthen; the fleſhy fibres make the proper *parenchyma* or fleſh of the wombe; that ſo the heate may be encreaſed for conception: by which alſo it may be, as by muſcles the voluntary motion of the wombe in drawing the ſeede into his cavity (as a Hart draweth a Snake out of the holes of the earth by drawing in his breath at his Noſethrills) and embracing it afterward is accompliſhed; haply alſo they have another uſe (ſayeth *Archangelus*) to thruſt out ſome recrements of the wombe, which cannot be cleaſed by the ſole compreſſion of the Muſcles of the *Abdomen*.

But in thoſe that are ſomewhat gone with childe, the trebble kinde of ſpermat- cal Fibres do appeare more manifeſtly, the right are inward which draw the ſeede, they are but few becauſe the ſeede is brought euen to the very mouth of the wombe by the yard. The oblique are in the middleſt and are moſt and moſt ſtrong, that they may retaine that which is conceiued till the due time; the tranſuerſe are outward very ſtrong alſo, becauſe of the force that is neceſſary in the deliuerance.

The veines and arteries which paſſe through the coates of the wombe are two fold, for two veines and two arteries are led thither from the ſpermat- cal [tab. 8. 11, tab. 9. fig. 1. H, fig. 2. ff, fig. 3. bb] veſſels, ſo many alſo from the Hypogaſtrical, which run vpward from below; [tab. 9. fig. 2. e, tab. 11. fig. 1. FF] that from all parts of the body as well below it as about it, blood might be miniſtered vnto it; for they bring not aliment onely to the wombe, but alſo to the Infant, as alſo they ſerue to empty the whole body in the menſtrual purgation. But the veines are greater then the arteries.

The one of theſe which proceedeth from the ſpermat- cal and deſcendeth from above, is diſſeminated through his whole bodie eſpecially through his bottome, to bring Aliment vnto it; yet the ends of the veſſels which are caried into the left ſide are vnited and become one with the ends of the veſſels which are diſtributed in his right ſide, that ſo the right ſide (for this is *Galen*'s opinion, in his 14. Booke *De uſu partium*, and the 9. Chapter) may take to it ſelfe ſome ſmall portion of whaeſy humiditie, which may by his acrimony ſtirre vp his action and procure pleaſure; as we ſee the whaeſy humors that are gathered vnder the ſkinne if they be heated, they ſtirre vp itching and a kinde of pleaſure withall. By this veine alſo the chiefe part of the menſtrual blood, eſpecially in women but not with childe, dooth flowe forth.

The other veine ariſeth from the Hypogaſtrical branch of the hollow veine at the ſides of the great bone about the ſhars; it is the greater and aſcendeth by the ſides of the necke vnto the middleſt of the wombe, where it mingleth it ſelfe with the former. This is diſtributed partly through the bottome of the wombe, partly through the necke of it. But the veſſels that paſſe through the bottome, are alwayes vnited (which ſaith *Fallopins*, Anatomists haue much neglected) by ſome branches, and that either without the wombe or in his ſubſtance: without the womb, the boughs of the vpper veine are ioyned with the ſmall branches of the lower at the necke of the wombe [tab. 9. fig. 2. e, with b] where on both ſides there are many veſſels, and theſe notable ones finger-fanged or placed like croſſe fingers, and being vnited doe paſſe into his ſubſtance and end or open into the cavity; which *Anaſtomoses* or inoculations of veines are more conſpicuous in women with childe, and thoſe whoſe courſes do flow or are neere vpon it. But if they be not vnited, then from the lower veine ſome branches are carried vpward, to be planted in the bottome.

The branches of this Hypogaſtrical veine being entred the ſubſtance of the wombe do mingle themſelues with the vpper branches proceeding from the ſpermat- cal, and the mouths or extremities of them reach vnto the inner cavity of it, and are called *Cotyledones* and *Acetabula*, to which in the conception the Liuer of the wombe or the after-birth doth cleaue, from whence the Infant receiueth aliment through the vmbilicall veſſels, and by which it is tied to the wombe. Through theſe, there arriueth more blood at the wombe then is neceſſary for the nourishment thereof all the while the Woman is chiding, that when conception ſhall happen to be, there may bee ſome quantiry of the Mothers blood at hand which is one of the principles of generation; as alſo that when the Infant is begotten and doth encrease, it may

may not want aliment according to that proportion it standeth in neede of; all which blond after the Infant is brought into the world, returneth back to the breasts and there is turned into milke.

At other times, because it is more plentiful then the wombe it selfe requireth, therefore it is like a superfluity excluded euery moneth, and if it bee retained it will corrupt and induceth many passions called *Hysterica*, which we call fits of the Mother, which yet are oftner procured by seed retheyned and corrupted then by blood. With this blood also other excrements contained in or amongst the blood and a whole heape of humors are purged sometimes in three dayes space, sometimes they flow longer, and commonly at the new moone the younger sort haue them, the elder in the full of the moone; which therefore we note, because when in Maidens the courses are stopped and they know not well when the time of their enacuation should be, we should apply our remedies either in the very end of the old Moone, or in the very beginning of the new.

Finally, the other part of the lower veine is inserted into the necke of the wombe, [tab. 9 fig. 2. e] whither if too much blood be brought by the spermatick vessels whilst the woman is with childe, it is exonerated not by the orifice or mouth of the wombe, but by the Anastomosis or inoculations of the veines into the necke of the same. Wherefore by these veines are some

women with childe euacuated/ which haue plethoricall and full bodies and fo more affluence of blood in the firft months after their conception then is required for the nourifhment of the Infant,) and not by the bottome of the wombe as otherwife in maides and women the men- ftrual blood vseth to be purged; otherwife the Infant would be choaked with the aboundance of blood and the orifice of the wombe muft neceffarily be opened, which would bring a dan- ger of abortment.

That which wee haue fayed of the Veins wee muft fay of the Arteries which accompany them, whose vfe alfo is in thofe that be not with childe to encrease the heat of the wombe, to bring vnto it fpirit and vitall blood, together with vitall faculty and heat, and by their motion to ventilate or breath the in-bred heat, to fir the bloud and fo to preferue it from putrifaction. But whether in the time of the courfes the arteriall blood be alfo euacuated, we ingenuoufly confefle our felues to be ignorant, faith *Bauhine*, fure we are that from thefe forenamed veffels, or that which is called the lap or priuy veine, there are carried certaine fmall veines and arte- ries to the lap and the hillocks or caruncles thereof.

The nerues of the wombe though they be fmal, yet are they very many, implicated or cou- ched one within another like a net, that they may confer exquisite fence vnto it. To the higher part of the bottome of it, they come from the termination of the branches of the fixt coniuga- tion which paffe by the roots of the ribs. To the lower part of the bottome and to the necke, from the marrow of the loyns & the great bone, (whence is that admirable confort between the wombe and the head efpecially the backpart of it) that feeling thofe things that are trou- blefome, the expelling faculty might be prouoked, and pleafure alfo conceiued in coition, (therefore about the lower parts they are more plentiful) as alfo the motion of the wombe wherein it draweth and imbraceth the feed of the man quickned and strengthened. For there are certaine fleshy fibres in the wombe as we haue fheweth already, which are in fteed of fmal muscles. And thus far of the fimple and fimilar parts of the wombe or matrix, now followeth the compound or diffimilar.

CHAP. XIII.

Of the Compound or diffimilar parts of the wombe, and particularly
of the bottome and the orifice.

The parts of
the wombe.

The bottome
or foale.

The hornes.

Although from the bottome of the wombe to the very lap or priuities there be but one continuatd paffage, yet becaufe in it there are many and diuerfe parts, therefore it is diuided into the vpper part or the bottome, -the mouth or inward orifice of the necke, the necke it felfe and the outward priuity or lap. The bottome which is properly the wombe and the matrix, *Hippocrates* in his Book *de natura pueri* calleth *μήτηρ*, *sinus* the bofome. *Galen* fo alfo *lib. 14.* and *15. de vfu partium*, and the 3. chapters, and fometimes *μήτηρ*, that is, a ca- uity or hollownes. This is the chiefe of al the parts of it, becaufe for it all the other parts were made; for in it is the Infant conceiued of the feed, (that we may fo fay according to our manner of fpeech, though indeed conception is nothing els but the wombs receiuing and imbracing of the feede) formed and diftinguifhed, nourifhed and increafed, made a liuing foule and prefer- ued cuento the infufion of the foule that diuine and immortall fubftance, and then it thrufteth it into the fea of the world and the tides of the fame.

This bottome then is the vpper [*tab. 5. L. tab. 8. p. tab. 9. fig. 1. A. fig. 2. & 3. c*] fheweth the bottom of the wombe of a woman with childe cut open] and broader part of the wombe placed about the fhare bone, that fo it might better be dilated as the Infant increafeth; on the out fide fmoother, equal and lined ouer as it were with a waterifh moyfture; and fendeth out on either fide about a certaine production or rather a corner, which *Herophilus* compareth to the turning of a halfe moone; *Diocles* and with him *Galen* in *lib. 2. de diffectione vteri*, chap. 2. and chap. 8. and *lib. 14. of the vfe of parts* chap. 11. calleth them *νεφέλαι*, that is hornes, becaufe the fuperficies of the womb is there fomewhat more eminent, euen as in the heads of young calues there are certaine buds where the hornes will afterwards grow forth. Into thefe the feed of the woman is powred out in thofe that be not with child, for into them the leading veffels of feed are inserted. [*tab. 9. fig. 1. & fig. 2. gg. fig. 3. hh.*] Thefe you may plainly fee if you cut the bottom of the womb through the midft; for on the infide at the orifice [*tab. 9. fig. 4. G*] you fhall perceiue on each fide a little cornet [*tab. 9. fig. 4. at A & B*] which by degrees [*tab. 9. fig. 4. AB*] inlargeth it felfe toward the bottome.

The

The vse of these hornes is, that the wombe might bee made more capacious for the enter-
taining of the Infant, because vpon these two bales as vpon stocks may two vessels or Infants
be built or generated. Wherefore the wombe, because it is the instrument of conception hath
a cavity, and yet but one, for there are in it no partitions or chambers: notwithstanding it is
vsually diuided into the right and the left bosome; the right in which male children are con-
ceiued, the left in which females are conceiued, as *Hippocrates* and *Galen* haue determined:
yet is not this diuision made by any wall or partition, but onely by a line or suture and seame
[*tab. 9. fig. 4. C D*] lightly rising vp but very obscurely through the middle part of the superfi-
cies, and running forward and backward according to his longitude; which line or suture is
called by *Aristotle* in the 3. Booke of his History of Creatures and the first Chapter *Διὰ τὴν*
mediā or the middle: and thence it is that the Ancients doe not call it *matrix* but *ma-*
trices, or the mothers, as if there were two of them, and say they are answerable in number
to the breasts, for it is a very rare thing that a womans wombe should be diuided into two
as beasts are. This cavity [*table 9. figure 4. A B*] is smooth and so narrow that it will scarcely
hold a common beane, and when it receiue the feede from both the Parents it is filled with
it, for any portion of feede that getteth into it filleth it, because it embraceth it so narrowly;
for in the least portion of feede that may be, the whole formative faculty is potentially inclu-
ded, out of which mingled and as it were fermentated and houghed vp the Infant is generated,
and is encreased by blood estuons comming to it for nourishment, by which also the sub-
stance of the wombe groweth into a great bulke; as a little sponge if it bee filled with water
will arise to a greater magnitude, which being pressed out againe the sponge will become as
small as before.

The bottome hath many pores or passages which are the mouthes of the *Corolydones* so cal-
led, by which the blood in the time of gestation issueth out of the veines of the wombe into
his cavity. In women not pagled for the most part it is lined within with a viscous or slimy
substance, of colour betweene a pale yellow and a red. The substance of the bottome of the
wombe is harder and more compact then that of the lap, yet softer then that of the necke, and
in the corners it is rugous.

From the lower part of the bottome there runneth a notable particle or portion of it resem-
bling the nut of the yarde [*tab. 9. fig. 1. C D*] which with his blunt head toucheth not the sides of
the necke; about an inch long it is, but as slender as a little finger, that it will scarcely admit a
Probe or a small penne at the most: but it is rough least the feede that is drawne should fall
backe, which commeth to passe in those women who haue this part slippery because their hu-
mors are faulty, & so become barren. This part which is betweene the beginning of the bot-
tome and the orifice, *Falopius* thinks was called the neck by *Galen*, *Soranus*, and the ancients. It
hath a manifest passage [*tab. 9. fig. 1. betweene C & D*] which maketh also another compound
part of the wombe.

This passage is the entrance into the bottome of the wombe, wherefore *Hippocrates* in the 1.
section of his Aphorismes, & the 51. Aphorisme calleth it *ὁμα τῶν ὀστέων, ἢ τῶν μὲν τῶν, ὡς ὕπερ*
the mouth of the wombe: *Galen* in his 14. Book *de usu partium* and the 3. Chapter, and in the
7. Chapter of his Booke *de dissectione uteri*, calleth it the inward orifice of the necke, for by
this the bottome openeth directly into the necke. This orifice is transuerse or outward like a
Plaice mouth, or most like to the passage in the nutte of the yarde: so that the whole orifice
with the transuerse slitte, is like the letter, *e*, small and wondrous narrow, that the feede once
receiued cannot easily fall backe, nor any thing hurtfull get into the cauitie of the wombe.
It is direct against the bottome, because the mans feede might passe in a right line through the
necke and it to the bottome; and so also it might be better drawne by the bottome, from
a leuell, for if it bee diuerred or turned aside many euils follow sayeth *Hippocrates* in his first
Booke of the diseases of Women, for then the wombe receiue the feede, but it falleth
backe againe out of the necke instantly. Then also the courses either come not at all, or with
great violence and disease: it is alwayes shut except onely at that time, when in coition the
bottome draweth the mans seed, and when the seed is conceiued or receiued then is it so clo-
sely shut vp sayeth *Hippocrates* in the 51. Aphorisme of the 5. Section, that a Needle or a small
Probe can hardly be thrust into it: and so it continues 9. months; for when women with child
yeelde seed it is not out of the bottome but by the necke of the wombe, as we haue sayd be-
fore.

Very rarely is it opened, and that either for the casting out of a false conception though
sometime a perfect conception remaineth behinde, or in superfetation where after one
conception

conception another is admitted. So likewise, when the wombe (not fit to conceiue) doth belch out againe the seed of both parties; or when as in pollutions or affections women that haue not conceiued do loose their owne seed; or when as in women vnburdened the courses or any offensiues humors are that way purged, as in the Whites, in which case oftentimes the whole body is purged that way, the womb at all not being affected; or when false conceptions alone are cast out, as the *Mola* or Moone-calse, and such like; or finally, when the Infant it selfe is borne into the world; for when that is perfected, this passage is so distended and openeth so wide, that from the bottome of the wombe to the very lap the cavity is equall, that through it the Infant may passe; which admirable worke of Nature, or Natures Maister God himselfe, we may wonder at, but not vnderstand saith *Galen* in his 15. book *de vfu partium*, & the 17. chapter.

But because it must be opened according to the magnitude of the Infant, & that by degrees (being of a thicke and fast substance [tab. 9. fig. 4. at G] and is yet thicker when the birth approacheth,) there cleaueth vnto it a certain viscid and slimy body like glew, that by the helpe of it, the orifice without feare of dilaceration or diuision may be distended and naturally opened. This is round like a crowne, and as often as the passage openeth, commeth away in an orbicular forme. The Midwiues call it the Crowne or the Rose. This Orifice, if it be too much loosened or opened aboue measure, as in ouer-moyst bodies, or in the Whites, or by reason of too frequent copulation as in Harlots, it bringeth barrennesse; so doth it also if it be too fat, or thick, or grow callous or hard; sometimes there grow in it the Scirrhus or the Cancer both incurable diseases, which happen especially when the Courses faile.

CHAP. XV.

Of the necke of the wombe and of the Hymen.

The necke of
the wombe.
14. vfu part. 3.
15. vfu part. 3.
14. vfu part. 4.
lib. 7. hist. 1.

He third part of the wombe is the neck called *Cervix* or *Collum vteri* [tab. 9. fig. 2. and 3. d, fig. 4. KK, in the first figure the necke is turned upward at BB] into which the yard passeth. This *Galen* commonly calleth *αὐχὴν τῆς μήτρας*, sometime *ῥαχιδος* and *σώμαχος*. *Aristotle* *μήτρα, καυλὸς καὶ σῶμα τῆς ὑέρας*, the matrix, the neck, & the gate of the wombe. It is a passage within the Cavity of the *Peritoneum*, called the *Bason* or *Lauer*, placed betweene the right gut and the bladder, whiter then the superficies of the bottome. It hath a deepe cavity and wide, (whence *Falopius* calleth it *the bosome of modesty*) but the mouth or entrance of it is much narrower. It reacheth from the inner [tab. 5. fig. 4. G] orifice of the womb, to the outward orifice [tab. 9. fig. 4. O] or very lap and priuity, and being long that the seede of the man may be brought to the orifice of the wombe it receiue the yard fitly like a sheath, wherefore the amplitude is answerable to that it must containe and is not broader then the right gut. It becommeth in the time of coition longer or shorter, wider or narrower as the yard is; and according to the womans appetite more or lesse turgid, more open or more contracted and direct; wherefore the length of it cannot belimited no more then the length of the yarde; and though it be continued with the bottome, yet it hath a diuers substance from it. For it is Membranous and Neruous, that it may better be enlarged or contracted, neither too hard, nor too soft.

The substance.

The straight-
nesse whence
caused.The folds of
it.

The substance of it, is somewhat fungous or spongy, like that of a mans yarde, for as it was necessary that the yard should be distended to fill this, so it was necessary that this in coition should be so contracted & straightened that it might straightly embrace the same, which happens by reason of many small Arteries which fill the passage with spirits, and so it becommeth narrower. Wherefore in women that are full of lust, or in the time of any womans appetite it strutteth and the Caruncles swell outward (which in Cowes and Bitches is so apparent, that their priuities seeme to be very much enflamed) and the cavity growes very straight. In yong wenches it is more delicate and soft, & becommeth every day harder, so that those that haue often conceiued and old women, haue it hard callous and as it were gristly, by reason of the often attrition and the frequent flowing of their courses. Whereupon *Herophylus* compared it to the weazon or winde-pipe. This when it is not distended is rugous, if it be much stretched it becommeth smooth and slippery, vnlesse it be in that part which endeth in the lap, but in the entrance of the passage and in the fore part, there are many round folds for the greater pleasure of louers which commeth from the attrition of them by the nut of the yard. These folds are in yong women smoother and narrower, and the passage straighter, that it wil scarce admit a finger,

ger, which is not from the closing of the sides of his necke, but by reason of the mediocrity of his passage, yet thorough it do passe not onely the blood in the monthly euacuations of grown Maidens, but also other corrupt humors in the disease of the whites or womens fluxe, which also we haue scene (being taught by *Aristotle* to obserue it) to bee purged this way in young children of foure or five yeere old.

A strange obseruation.

The attrition of these folds and their extension in the first society of maids with men, *Soranus* thought to be the cause of some maydens paine in deuirgination or losse of their maidenhead as we speak, & because certaine veines passe by them these being broken by the husband the blood issueth sometimes in great aboundance: but the neck (when neither the seed is sent in, nor the Infant is excluded, but at other times) is writhen and oblique, for being loosned and falling into it selfe, it is necessary that it must haue certaine contorsions or wrethings, that the parts within contained may be defended from outward cold, wherefore then it is shorter and narrower, but in coition it is distended vnto the measure of the yarde, in the birth to the measure of the Infant which is to passe through it: and therefore when the courses flow, but especially when the time of deliuerance is at hand, the neck becoming right, straight and open, women are most subiect to take cold by it.

The cause of paine in deuirgination of a Maid.

When women take most cold

In the end of this neck, immediately aboue the necke [*tab. 9. fig. 2. m, fig. 3. e, fig. 4. L*] of the bladder, they place in Virgins the *Hymen* or *Eugion*, [*tab. 9. fig. 4. n*] which many will haue to be a slender Membrane, neruous, not thicke, placed ouerthwart that it may shut the cavity of the necke of the wombe, yet perforated in the midst like a ring, that in growne maids it will admit the top of a little finger, that through it the courses may passe sprinkled also with veines. This they say is broken in the deuirgination, from whence comes the paine & effusion of blood, and after it vanisheth as doth the bridle of the nut of a mans yarde: with this also are the wings or lips of the lap tyed together, because there is no vse of a large entrance before coition.

The Hymen.

But let vs set downe with your patience, the true History of the *Hymen*, which *Senerimus Pinus* the French Kings Chyrurgion hath diligently and at large recorded.

A discourse of the Hymen out of *Pinus*.

In the middle of the trench which is in the great slit or clift lyeth alwayes hid the orifice of the Maidens bosome of modesty, being placed not in the end of the trench, but in the inner end of that production which is annexed to the trench. This production which is peculiar to Virgins, is as long as the little finger is broad in the midst, & is incircled aboue with a round cavity. The figure of it is round, yet determineth into a sharpnes, and in the end hath one notable passage which will admit the top of the little finger.

The substance is partly fleshy partly membranous, being compounded of Caruncles or little peeces of flesh and membranes. The Caruncles are foure, and are like the berries of the Mirtle, in euery corner of the bosome one; the membranes tying them together are also foure, which are not disposed ouerthwart but runne all right downward from the inner end of the sayed bosome, and are placed each in the distances betweene euery Caruncle, with which they are almost equally extended or stretched forth. But these both Caruncles and Membranes are in some bodies shorter or longer, thicker or thinner then in others, as also the orifice at the end of them is in some wider in some narrower, and then especially is at the straightest when the Caruncles and the fleshy Membranes are neerest ioyned together, from whence comes either greater or lesse payne in deuirgination or deflowering, which *Terence* calleth *The sharpe coition*.

The caruncles.

Whence cometh the paine in deuirgination.

All these particles together make the forme of the cup of a little rose halfe blowne when the bearded leaues are taken away. Or this production with the lappe or priuity may be likened to the great Cloue Gilly-flower when it is moderately blowne. *Galen* in the second Chapter of his Booke *De uteri dissectione* likeneth this production to the prepuce or foreskin of a man, because it is somewhat long and perforated in the end; yet is it a little more fleshy and softer then the fore skin. It is called *Hymen quasi Limen*, as it were the entrance, the pillar, or locke, or flower of Virginitie. For being whole it is the onely sure note of vnsteynd Virginitie (yet some also haue other quaint deuices to try Virginitie with; as if a third measured from the tip of the nose along the fore head to the end of the sagittal future or seame, will also fitly encompassse the Womans necke,) for when the yarde entreteth into the necke of the wombe, when the fleshy Membranes which are among the Caruncles, are torne vp euen to their rootes, and the Caruncles are so fretted and stretched, that a Man would beleue they were neuer ioyned; some notable vessels are opened, and in the breaking is payne, which in young wenchies is more because of the drynesse of the part, but the effusion

on of blood the lesse, because of the smalnesse of the vessels. In elder maids whose courses haue now some good time flowed, there is lesse paine, because of the moysture and laxitie of the Hymen; but the effusion of blood is greater because the vessels are grown larger and the blood gotten a fuller course vnto them. For all virgins although they be neuer so mellow, yet haue their first coition painfull, but some more some lesse; vnlesse they then are menstruous, or haue beene within three or foure dayes, for then they admit the yard with lesse trouble, because of the relaxation and lubricity of these moist parts whereupon the Membranes are dilated with little or no paine. And this hath beene the cause why some men haue vnworthily suspected the vncorrupted chastity of their wiues. Wherefore it were fit the mothers or women friends of such virgins should haue care of their honor, by giuing warning to their Bridegroomes of their brides purgations, if at that timethey bee vpon them; and very often they are when the Brides are growne women and well complexioned, because the ioy and priuate pleasures of affianced young folkes, as also their dancings and frolike diet with such like, do often by moouing the body accelerate and hasten such purgations, and being come do cause them longer to endure.

The torne Membranes of this production in their vtmost compasse indented, do sometimes hang downe on either hand in the sides by the cleft like vnto valves (for so *Pinam* calleth the) or leafe-gates, which are much lesse then the *Nympha*, but of the same figure and vse. These are not lost, before a woman hath borne a childe, but are reserued being returned vpward to the orifice of the necke of the wombe, now made much wider then in the time of virginity: but in those that haue often brought forth large limb'd Infants, or whose wombe hath falne downward and so the necke of it beeing inuerted or turned, they are lesned and contracted or drawne vpward toward the necke and so perfectly vnited to the caruncles to which they adhere, that they seeme to be vtterly perished.

But the foure Caruncles which are like Mirtle berries, whereof one and the foremost is placed at the orifice of the bladder, another and the hindmost with the two laterall situated not ouer-thwart but length-wise; these I say doe remaine as long as the woman liueth, though she liue very long. Their vse, as also that of the Membranes when they are reflected vpward, is immediately to stop the orifice of the necke of the wombe as a fleshy production doth stop the necke of the bladder; they hinder also the ingresse of cold aire, dust, or any other such like (in which seruice they are assisted also by the *Nympha*, and the wings of the lap or priuity) and in coition doe aggrate the member of the man; for when they are heated and grow turgid with spirits, they so constringe the yard especially in yong women, as if it were closely pressed in the hand.

Next to these is the rugous or plighted chinke or riste, which is placed as it were in the trench of the great Cleft, and like a narrow valley leadeth the way by a round cavity into the inward parts, and maketh the outward orifice of the neck. *Galen* in his 15. book *de usu partium*, and the 3. chapter, calleth it *σώμα τραχήλου*, or the outward orifice of the necke of the wombe, by which the yard is receiued to prouoke the parts of the woman to yeelde their seede, and to infuse his owne. This orifice sometimes by a disease called *Rhagades*, otherwhile by a great cicatrice or scar bred after some other exulceration, is so streightned, that such women can no more admit their husbands; sometimes through a notable exulceration after a hard trauell it groweth cleane vp, which once we obserued (saith *Banrhine*) in an honorable Matron in whom appeared not any signe of an entrance, but after a whole yeere keeping her owne counsell her courses being all that while stopped, she was tormented with many convulsive fittes of the mother, and so perished through her owne default.

Heere is also to be obserued a skinny Ligament in the backe part of the outward Orifice of the necke, which in virgins is straighter and is couered by the trench, but in those that haue brought forth it is much more lax & loose, so that the loosenesse of this Ligament or skinny rye is the only signe that a woman hath borne a childe; for it is so alwayes in such and in none but such, vnlesse in others the wombe do, or haue falne downe; to this signe there happeneth sometimes another, and that is the ruggednesse or small plights of the skiane of the lower belly, which being strained in trauell remaineth euer after rugous.

CHAP. XVI.

Of the Lap or Priuitie.

The last dissimilar part of the womb, *Galen* in his 14. and 15. Books *de vsu partium*, the 6. and the 3. chapters, calleth *αἰδορ γυναικείον*, in Latine *pudendum muliebre*, that is, the womans modesty, [*tab. 9. fig. 2. l. fig. 4. neere n. o.*] of some *Vulva*, as it were *vallis* a valley, or *Valva* a Flood-gate, because it is diuided into two parts by a cleft, which like Flood-gates or leafe-doores are easily opened or shut as neede is. We will call it the lappe. It is that part into which the necke of the womb determineth, and is seated outwardly at the forepart of the share bone, and is as it were a skinny addition of the neck, as *Galen* speaketh in his 14. Booke *de vsu partium*, and the 6. Chapter, answering to the prepuce or foreskin of a man. In this there are many parts to be discerned without dissection. Of which some are altogether outward, offering themselues before the wings be displaid; others inward, not appearing before the wings be opened and separated on both sides. Of which we will first entreate.

There is therefore a large trench, in which are the passage of the neck [*tab. 9. fig. 2. m. fig. 3. e. fig. 4. l.*] of the bladder with a Caruncle, the *Nympha* and the *Clitoris*. For, although the Hymen and his membranes and caruncles with the flitte and the orifice of the necke may also be seene without dissection, yet because they pertaine not to the lap but to the neck of the wombe, we haue described them already.

At the end therefore of the necke of the womb, immediately vnder the share-bone, lightly above the lap it selfe, on the fore-part there is an entrance or passage which commeth out of the implantation of the neck of the bladder, by which the vrine is let out into the utmost part of the neck of the wombe, or rather into the lap it selfe, euen as in a man the vrine floweth out of the passage or channell which is appointed for the seede. In the compasse of this there is a caruncle [*tab. 9. fig. 4. p.*] or a little fleshy hillocke by which this passage is couered, that after the vrine is let go, the outward aire should not get into the bladder through his necke which is short and wide; which caruncle also as it regardeth the trench, strengtheneth the leafe-gate or locke of virginity.

The *Nympha*, so called by *Galen*, of others *αἰδορ γυναικείον*, because they first admit the man, of the Latines *Ala* the wings, of others skinny caruncles, are two productions on either side one, in the beginning almost ioyned; which arise from a welt or gard of the skin of the substance of a Ligament in the backe part of the orifice of the neck, and lying hid between the two lips of the lap and almost alwayes touching one another, do ascend to the end of the commissure or meeting of the share-bones. These being ioyned doe make a fleshy eminence, and couering the *Clitoris* with a fore-skin ascend with a manifest rising Line to the top of the great cleft: they are longer from their middle outward and do hang sometimes a little foorth through the great cleft, without the lips of the lap, & that with a blunt angle, being otherwise of a triangular figure.

They are very like in colour and shape to that part of a Cockes combe which hangs vnder his throate. Their substance is partly fleshy, partly membranous, soft & fungous, & they are inuested with a thin coate. Sometimes, they grow to a great length on one side, more rarely on both; and not so ordinarily in maidens as in women, (and then it is called by *Ruffus* *κέρκωσις*) what through the affluence of humors, what through attrectation, that for the trouble and shame (being in many Countreies a notable argument of petulancy and immodesty) they neede the Chirurgions helpe to cut them off (although they bleed much and are hardly cicatrised) especially among the Egyptians, amongst whom this accident (as *Galen* saith) is very familiar. Wherefore in Maidens before they grow too long they cut them off, and before they marry.

These *Nymphae*, beside the great pleasures women haue by them in coition, doe also defend the wombe from outward iniuries, being of that vse to the orifice of the necke which the fore-skin is to the yard; for they do not onely shut the cleft as it were with lips, but also immediately defend the orifice as well of the bladder as the wombe from colde aire and other hurtfull things. Moreouer, they leade the vrine through a long passage as it were betweene two walles, receiuing it from the bottome of the cleft as out of a Tunnell: from whence it is that it runneth foorth in a broad streame with a hissing noyse, not wetting the wings

The wise disposition of nature.

The outward parts of the lip.

Oris the great fissure.

Clitoris in Greeke *κλειτορις* commeth of an obscene word signifying contumeliation, but properly it is called the womans yard. It is a small production in the vpper, forward [tab. 9. fig. 4. m.] & middle fatty part of the share, in the top of the greater cleft where the *Nymphes* doe meet, and is answerable to the member of the man, from which it differs in the length, the common passage and the want of one paire of muscles; but agrees in scituation, substance and composition. For it consisteth of two neruous bodies (which *Laurentius* calls ligaments) round, without hard and thick, but within spongy and porous, that when the spirits come into it, it may be distended and grow loose when they are dissipated; these bodies, as those of the mans yarde, are full of black, thick and sprightfull blood.

Their originall is from both the share-bones where they ioine with the bone of the hip & are seuered at first, but after they are gone a little foreward they are vnited about the coniunction of the share-bones, and so make the body of a yard hard and solide, and haue a termination like the nut, to which on either side is adioyned a small muscle.

The head is properly called *Tentigo* by *Iuuenal*, which is couered with a fine skin made of the coniunction of the *Nympha* as it were with a fore-skin. It hath an entrace but no through passage; there are vessels also running along the back of it as in a mans yarde; and although for the most part it hath but a small production hidden vnder the *Nymphes* and hard to be felt with curiosity, yet sometimes it groweth to such a length that it hangeth without the cleft like a mans member; especially when it is fretted with the touch of the cloaths, and so strutteth and groweth to a rigidity as doth the yarde of a man. And this part it is which those wicked women doe abuse called *Tribades* (often mentioned by many authors, and in some states worthily punished) to their mutuall and vnaturall lustes.

The vse of this part is the same with the bridle of the yard; for because the testicles of the women are far distant from the yard of the man, the imagination is carried to the spermatieall vessels by the motion and attrition of this *Clitoris*, together with the lower ligatures of the wombe, whose originall toucheth, cleaueth and is tyed to the leading vessels of the seede, and so the profusion of their seede is stirred vp for generation, for which businesse it was not necessary it should be large: wherefore although by this passage their seede is not eiaculated, yet by the attrition of it their imagination is wrought to call that out that lyeth deeply hidden in the body, and hence it is called *æstrum Veneris* & *dulcedo Amoris*; for in it with the ligaments inserted into it, is the especiall seate of delight in their venereall imbracements, as *Columbus* imagineth he first discovered.

For Nature, who wisheth as *Galen* saith in his 14. book *de vsu partium*, and the 2. chap. that if it might be, her work might be immortall, and falling from that hope because of the contrariety of the matter, hath giuen to all creatures both the instruments of conception, and hath also infused into them a strange and violent kind of delight, that none of the kindes of creatures should perish but remaine euer after a sort immortall. And truly it was very necessary that there should be a kinde of pleasant force or violence in the Nature of mankind to transport him out of himselfe or beside himselfe as it were, in the act of generation; to which otherwise being master of himselfe he would hardly haue beene drawne: which extasie, (for it is called a little *Epilepsie* or falling sicknes) is caused by the touch of the seed vpon the neruous and quicke sensed parts as it passeth by them.

To draw to an end. Those parts which appeare outwardly are the great slit, the lips and the groyne or leske: for as soon as the lippes are diuided, there appeare three clefts or slits; one and the greatest which is the first and vtmost, and two lesser and collaterall betweene the *Nymphes*, the vse of which is to close vp the parts more safely. But that cleft which is called *orisma* or the great and long fissure is made by the lips and bendeth backward to the Fundament from the share-bones downward toward the cleft of the buttocks: for it ought to bee longer then the orifice, least the Infant should bee hindered in the birth, because the skinne is much thicker and not so yeelding as are Membranes: and the more it tendeth backward the deeper and broader it is, and so degenerateth into a trench or valley, representing the figure of a boate, and endeth in the welt of the orifice of the necke. die of his trench is placed the orifice of the necke, and this is the fissure that admitteth the yard, and is a part thought too obscene to looke vpon; which is the reason sayth *Pliny* that the carcasses of women doe floate in the water with their faces downward, contrary to mens which swimme vpwrd; euen Nature it selfe yeelding to modesty; although the cause also may be referred to the largenes of a womans belly, as also because the water getting into the lap filleth the belly, & for that the waight of her breasts turneth her body downwards.

The two lips which *Hippocrates* in his Booke *de locis in homine* calleth *neplava*, folow next, which make the fissure of the outward orifice; they are long, soft and of a skinny substance and fleshy withall, after a sort glandulous and spongy, and vnder them haue a hard fat and are as it were callous. They are couered with a thin skinne, and are in married women more smooth and depressed.

The extuberations of these winges are called hillocks or mountaints (*Vesalius* calleth these extuberations *ala* or wings, the other *labra* or lippes) and the mount of *Venus*: these in mature or ripe women are adorned with haire, the bush of which is called *pubes* or *pecten*. These hayres are in women more curled then in Virgins, & do reach as a covering vnto the lippes; the lippes were made for ornament and for defence that the wombe might be kept from refrigeration.

But if in the demonstration of the wombe we will begin at the externall parts, wee must proceede by the guide of a vterine probe, and then the partes will thus arise. First the region of the share-bones, then the bush, the hillocks whereon the hayre growes, the two lips, the great outward fissure betweene the lippes making the outward orifice, the trench like a boate, the two smaller clefts or fissures between the Nymphes, the two Nymphes themselves; the *Tentigo* or head or nutte of the *Clitoris* covered by the Nymphes as by a foreskin and the impassable passage of it; the two bodies of the *Clitoris* and two muscles belonging to it; the passage of the necke of the bladder with the Caruncle or fleshy hillocke which couers it; the skinny ligament which wee sayd was a signe whether a woman had beene a mother or no; the rugous fissure or cleft making the orifice of the necke; the foure Caruncles and the foure membranes between them making the *Hymen* in virgins, the necke or canale of the wombe, all these may be seene without incision, the rest must be found by incision.

And thus much of the parts of generation belonging to women; now the discourse of Hermaphrodites or of *Androgynes* that are both man and woman, wee will referre to another place.

CHAP. XVII.

Of the wombe of a Sheepe and a Dogge.

Now because in the want of womens bodies it is an ordinary custome for Anatomists to exercise themselves and their auditors in the dissection of the wombes of other creatures; therefore I will shortly exhibite vnto you the wombe of an Ewe and a Bitch, as well by way of history as also by a Table carued onely for that purpose.

In an Ewe therefore the necke of the wombe reacheth from the priuity to the top of the Holy-bone, where beginneth the bottome of the wombe spreading it selfe a litle in the region of the Loynes. This wombe is a long body pressed on either side, but toward the end it parteth into two processses looking vpwrd and bending outward very like the hornes of a Ramme. [table 14. figure 2, E] The outward superficies of the bottome, after the manner of membranes is glib and smooth and is tyed to the neighbour parts (euen as the necke is tyed) by membranous ligaments arising from the *Peritoneum*, through which there are also vessels disseminated which are sent vnto the wombe. The processses of the bottome where they are diuided asunder on the insides are also smooth, and doe growe to many particules of the belly, but their outsides are continued with the bottome of the wombe it selfe by certaine membranes.

The bottome also hath two cauities [tab. 14. fig. 2. D] which meete at his orifice [tab. 14. fig. 2. C] that reacheth vnto the necke. The cauities or bosomes are somewhat yellowish, and haue in them many risings or swellings like little knobbes, which after the creature hath conceived, open themselves and make dennes or cauities. If they breed one Lambe, then

The wombe of an Ewe or a Cow. The Figure.

Connexion

The bottome

The first figure sheweth the wombe of a dog, because those may more plentifully be gotten for dissection. The second figure sheweth the wombe of a Cow (altogether like that of a Sheepe, saving that it is bigger, that the horns might better appeare, because it is fit that young Anatomistes should exercise themselves in the dissection of the wombes of sheepe. The third sheweth the after birth or cleansing of a Cow. The fourth hath another representation of the cleansing of a Cow.

TABVLA XIII.

- I. Figure.*
A. The spermaticall Veine and artery.
B. Portions of the spermaticall vessels reaching branches to the upper part of the wombe.
C. The Testicle and the Leading vessel.
D D. A Membrane tying the womb to the Peritonaeum.
E. A veine and artery distributed to the necke of the wombe, and the lower part of the bottome.
F. The right side of the bottome of the wombe, covered with the outward coat.
G. The left side of the bottome of the wombe halfe of it freed from the outward coat.
H. The outward covering at G, the inward H.
I. The left leading vessel separated from the testicle.
K. The place where is the orifice of the bottome of the womb.
L. The necke of the womb, the left side is vncouered from the outward coat.
M. A part of the necke of the bladder.
N. The skin left at the primity.
- II. Figure.*
A. The left testicle.
B. The vessel leading the seeds into the hornes of the wombe.
C. The place of the orifice of the bottome of the wombe.
D. The places where the wombe is divided into two parts.
E. The two parts of the womb resembling the hornes of a Ram.
F, G. The outward coats of the wombe at F, the inner at G.
H. A portion of a Membrane, ioyning the womb to the Peritonaeum.
- III. Figure.*
A A. The outward covering of the Calfe.
B B. The places where the outward covering is tied to the womb and admitterh the vessels, where also there is a fleshy substance, which is likened to the flesh of the Splene.
C C. The meeting of the veines and arteries through this covering, for the making of the vmbilicall vessels.
D. The place where those veines and arteries disperfed through this covering, are gathered together a little before they make the vmbilicall vessels.
- IV. Figure.*
A A. A fleshy substance growing vpon the outside of the vter covering of the Calfe, which compasseth the covering ouerthwart, otherwise then in men.
B B. That part of the outward covering which is not ouer growne with that fleshy substance marked with A A. but is branched with veines and arteries.

then onely one of the cavities is dilated; if two, then in each cavity is one containd. The membranes of this wombe are two, one externall [tab. 14. fig. 2, F F] from the Peritonaeum, from which the Ligaments no proceede, and wherein the vessels are ledde vnto the womb. The other internall [tab. 14. fig. 2, G] and proper, which compasseth the womb round about. Between these coates are disperfed an infinite number of veines & Arteries, strangely implicated or folded together; and these implications are heere more manifest by much then they are in the womb of a woman, although the coates of her womb be rent asunder. About these vessels there appeare many round bodies like little knubs, which in women are called *Acetabula*, [tab. 9. fig. 4, about E and D] very small they are, and nothing else but the mouths of the vessels.

The Testicles. Their Testicles are situated at the sides of the wombe [tab. 14. fig. 2, A] vnder the tops of the hornes. The vessels which attaine vnto the Testicles and the wombe are the very same with those of a woman both in their originall and their passage, excepting those which leade the seede into the cavity of the womb, whose implantation in these creatures is much more manifest, so that you may easily enter a Probe into them. Such also and after the same manner is the fashion of the wombes of a Goate and of a Cow.

The womb of a Bitch. But the womb of a Bitch, [tab. 14. fig. 1] hath a neck [tab. 14. fig. 1, L] reaching but to the beginning of the Holy-bone. The bottome is presently divided into two parts, which by degrees determine in a sharpe end & do not turne round like the hornes of the womb of an Ewe or Cow, but run out straight. And because these creatures beare many whelps at once in particular parts of their womb, these parts are distinctly implicated or rowled vp like the guts,

These two parts of the bottome [tab. 14. fig. 1. FG] do end in a common orifice, [ta. 14. fig. 1, K] which reacheth vnto the vpper part or seate of the necke. It hath a double coat, one outward from the *Peritoneum*, [tab. 14. fig. 1, DD] from which it hath his processe, the other inward.

The two parts of the bottome.

The Testicles [tab. 14. fig. 1, C] are placed at the tops of the two parts of the bottome. The vessels are like those of an Ewe before described, but they haue no such knobbes in the cauities, as we spake of in the former.

The testicles vessels.

It is a strange thing which *Gesner* and others doe write, that in *Paria* a Prouince not farre from the Region of the *Patagons* in the West India, there is a creature found which our Countrey men call a halfe Fox. For it hath two wombs, one inward in which they generate as other creatures do, the other outward scituated vnder the former wherein they cherish and defend their Cubbes, and out of which they seldome take them but when they would sucke. Heere we will put an end to our History of the parts of Generation, and come to the Controuersies.

A strange creature in the West India.

A Dilucidation or Exposition of the Controuersies of the fourth Booke.

QUEST. I.

Whether the Testicles be principall parts or no.

Aristotle and the *Peripatetick* philosophers do admit but one principall or chiefe part in the body of man which is the Heart; but their opinion is long agoe hissed out of the Physitians Schoole. Many do accuse *Galen* of leuirty & inconstancy in assigning the number of the principall parts. For sometimes he accounteth the Testicles among the principall parts, sometimes he excludeth them, but it will not be hard for vs to reconcile *Galen* vnto himselfe.

The Peripatetians.

Galen accused but redeemed. Lib. de sem. de arte parua. G. de usu part. G. de placitu.

The testicles alter the temper, habit, and manners.

The Testicles, because they are the chiefe Organes or instruments of procreation and by procreation mankind is preserved, are therefore to be accounted principall parts; and haply so much are they more excellent then the heart, by how much the species or whole kinde is more noble then one *individuum* or particular of the kinde. Surely the power and vertue of the Testicles is very great and incredible, not onely to make the body fruitfull, but also in the alteration of the temperament, the habit, the proper substance of the body, yea and of the manners themselves. In these doth *Galen* place, beside that in the heart, another hearth as it were of the inbred heate, and these are the household Goddesses which doe blesse and warme the whole bodye. Hence it is, that the Egyptians in their Hieroglyphickes doe paint *Typhon* gelt, signifying thereby his power and soueraignty to be abolished and decayed.

Why the Egyptians painted Typhon gelt.

That they change the temperament it is manifest, because the testicles being taken away or but fretted, contorred or writhen, yea refrigerated, or hauing suffred convulsion, there presently followeth a change from a hot to a cold temper, and in olde time it was accounted a singular remedy for the leprosie to cut off the Testicles, and to this day we vse to apply Epithymations to them, and finde that they doe wonderfully corroborate and strengthen the whole frame of the body. And it is ordinary for women (and that not without reason) to presume much vpon the death or recovery of children by the firmenesse or loosenesse of these parts; yea *Hippocrates* himselfe saith in his prognostickes, *That the Convulsion of the testicles and priuy parts do threaten danger of death.*

The temperament.

Prognostication by the Testicles. The habite.

We see also that in gelt men called Eunuches, there is a change of the whole habit and proper substance of the body, for they become fatter and smooth without haire; the flower also of their blood decayeth and their vessels or veines lose their bredth and capacity, and

all vigour of lust and desire of ioylity is extinguished; beside the flesh of such creatures loseth the former tast and smell; for whereas before it breathed out a certaine vnsauoury and rammish sowrenesse, after they are gelt it becommeth sweete and pleasant to the taste.

The manners.

Concerning the chaunge of their Manners, that is notable of *Auenzoar* the Arabian, where he saith, Eunuchs haue a shrill and piping voice, euill manners, and worse dispositions, neyther shal you lightly finde one of them of a good inclination, or not broken witted. *Claudian* against *Eutropius* inueyeth thus against Eunuchs.

Adde quod Eunuchus nulla pietate mouetur,

Nec Generi natusque cauet.

The Eunuch is deuoid of pietie,

Both to his Parents and his Progenie.

Comparison

Galen redce-
med.

Atwofold in-
fluence of heat.

Albeit in the seuenth Booke of the *Institution* of *Cyrus* it is recorded, that this kind of men is quiet, diligent, and especially faithfull: but we may answere that they are quiet because they are dull and blockish; diligent because they are seruile and base-minded; faithfull because they haue so much distrust of themselves. But howsoeuer, whence comes trow wee this so sudden alteration of the temper, habit and maners? *Aristotle* thinketh that the heart is stretched by the testicles, and therefore relaxed when they are cut away, and so a common principle affected, because the strength of the Nerues is relaxed or loosened in their originall or beginning. Euen as wee see it commeth to passe in instruments, which haue a more acute or trebble sound when the strings are stretched, and a lower and more remisse when they are loosened; right so in Eunuchs, the Testicles being taken away and so the heart affected, the voice and very forme becommeth womanish; for a principle though it be smal in quantity, yet it is great in power and efficacy.

Against this opinion of *Aristotle* *Galen* disputeth in his Booke *de Semine*, and we in our next exercise shall prosecute it at large: for neither doeth the strength of the heart depend vpon the contention or stretching of the Testicles but vpon his owne proper temper; neither if the heart needed any such tension or stretching, were the testicles pinnes fitting for the same. The Common opinion is that all the other parts are heated by the repercussion of heate from the Testicles vnto them; but because their substance is soft and rare, and reflection or repercussion is vsually (especially if it be any thing) from thigh and hollow bodies, I imagine that their small and slender reflection can be no cause or author of so powerfull a heat as the parts do stand in need of. *Galen* referres this alteration to the native and ingenit temper of the testicles themselves; for in the place last before named he sayth, that in them there is another fountaine or furnace rather of heate, euen as there is in the heart. But vnder correction it seemeth to me more reasonable, that the heate of the Testicles is not so much from their native and in-bred temper, because they are without blood and like vnto Glandes, as by reason of the seede conteyned in them; for where that is it heateth the whole body, distendeth yea enrageth it. For *Hippocrates* saith, that seede is of Nature fiery and aery; by the aery part it distendeth the whole frame of Nature, and by the fiery setteth it on worke, or a gog as we say, transporting not the body onely, but the minde also from reason to rage. For as the least part of mortall poyson in a moment changeth the whole body; so is it in seede, whose quality is so active and operative, that it darteth forth as it were by irradiation his beames through the whole body. And thence it is, that we see gelt creatures are not so stirring as others, whose many motions do stirre vp and so encrease their heate.

It may be objected that *Galen* in another place attributeth onely to the Liuer and the Heart power to change the whole body, not to the Testicles. For thus hee sayeth: *Those that haue hot Liuers haue also all their Habit hot, vnlesse there bee some obstacle in the Heart: on the other side they that haue hot Heartes haue also hot Habites, vnlesse the Liuer doe vehemently oppose against it:* but of the Testicles not one worde or any mention at all; this obiection may thus be satisfied.

There is a twofold influence of heate, one immediate, another mediate. The immediate influence of the two-fold spirits and bloud and with them of the heate, is from the heart and liuer by the veins and arteries. The mediate is from the Testicles into the whole body indeede, but by the mediation of the Heart, the Liuer and the common vessels. For the Testicles haue no peculiar vessels by which they might deriue their influence into the whole body; but they impart this power and faculty of alteration to the Heart by the arteries, to the Liuer by the veins; from which it is againe reinfused into the particular members.

It will be objected that this faculty of alteration proceeding from the Testicles is infused

not

not bodily but onely operatiuely; what neede then hath it of a conduite or pipe either arteriall or venall? But I answere, that faculties doe not vse to bee infused or transfused but by the mediation of spirits, which although they wander and gad vp and downe the body; yet notwithstanding they stand neede of peculiar receptacles to containe them in, such as are the veines, nerues, and arteries. So poyson although in the specificall or essentiall forme it opposeth the heart, yet is it carried in a moment of time and matter to the heart through the arteries and spirits wherein the faculties haue their consistence.

How faculties are infused.

Such therefore is the excellency, such the admirable faculty of the Testicles, as well in procreation of seede (as we shall declare in our next exercise) as also in the alteration of the temper, habit and manners; and in that respect are they called by *Galen*, *principall parts*.

Comparison

But there want not aduersaries who would thrust them out of this ranke of dignity; although their arguments are very weake. First they say *Galen* in two places defineth a principall part, in the first by *Necessity*, in the second by *communication of a faculty or some common matter*. But for the Testicles there is no necessity of them, for *Eunuches* liue without them, neither is there any faculty proceeding from them; for the animall faculty proceedeth from the braine, the vitall from the heart, the naturall (to which the faculty of procreation is referred) issueth from the Liuer the chiefe of all naturall partes. Moreouer from the Testicles there is no matter communicated to the whole body, for they haue no spirits proper vnto them, no vesselles which runne through the body by which it may bee conuayed; but these are trifles.

Obiections.

What a principall part is according to *Galen*.

For we confesse the Testicles are not necessary for conseruation of the life of the *indivisible* or singular man, but for propagation of the whole *species*, or of *mankinde*, they are of absolute necessity. Wherefore they are principal parts in respect of mankind, not in respect of this or that particular man. For the propagation of mankind is onely accomplished by procreation: procreation is not without seede, seed is only concocted and perfected by the Testicles, to which the spermatike vesselles doe serue as well for preparation as for conduction and leading of the same.

Answered.

But me thinkes I heare the *Peripatetians* obstreperously deny the Testicles this power of procreation of seede, against whome we will in the next place bend our forces.

Obiections of the preparation of seed.

QVEST. II.

Of the vse of the Testicles.

Concerning the vse of the Testicles there are diuerse opinions, and those farre differing one from another. *Aristotle* denyeth them the vertue of making seed and attributeth it onely to the spermatike vesselles, because many creatures want Testicles, as Fishes and Serpents, which yet enioy a coition, and doe auoyde perfect seede able to propagate their *species* or kinde. That a Bull or Horse hauing lost their Testicles may yet presently couple with their Females and procreate, and finally because they accomplish or fill vp no part of the passages; that is, haue no sociery with the spermatike vesselles. He taketh knowledge of other vses of these Testicles which he maketh to be threefold.

Aristotles opinion. His arguments. 3. *Hist. Ani. I.* 6. 1. *de gener. Anim. 4.*

The first, that they establisth the motion of the seede, and hanging at the vesselles inuerted or writhen with a wonderfull art, doe hold them together and make them more patent and ample, (as we see weauers hang waights at the strings of their warp) and therefore when they are cut off, the spermatike vesselles are contracted and their passages occluded or shut vp so as the seede can haue no passage. The second vse of the Testicles is for the strength of the heart, for by these as by certain waights the heart is streatched, and thence proceedeth the change of the Temperament and whole habit when they are taken away, the bridle being loosed and the strength of the heart so as it were dissolued or resolued. The third vse I gather out of his Problemes; that by their waight & poyse they should helpe the tension or erection of the yarde. And this is *Aristotles* opinion of the vse of the Testicles, which we will now bring to the touch-stone to see how it will hold.

His threefold vse of them.

Comparison.

For the first vse he may well be confuted by himselfe: the vesselles of seede sayeth he are writhen and intorted with wonderfull art, and implicated or foulded vp in many boughts and circumuolutions; the waight therefore of the Testicles should bee so far from dilating their

Confutation of the first vse

their passages, that if they did stretch them they would rather draw them out in length euen vnto the feete. But the truth is, that these vessels are so firmly tyed to the neighbour parts that they admit no stretching or tension at all, or if they should be stretched they would not onely not be dilated, but they would become narrower and straighter; for vessels when they are stretched out in length cling closer together.

No vse of any
sensible cau-
ty for the seed

Obiection.

Solution.

But what vse is there of any such sensible cavity or amplitude for the excretion or mission of seede? Is there not seede containd in the substance of the Testicles and of the *Epididymis* in which there is no sensible or conspicuous cavity? and is not the seede led along by the leading vessels to the small bladders and *Prostate*, and there kept in readines for effusion without any cavity? The seede it selfe is hoven with abundance of spirits which maketh it to passe *orgasmo*, that is, with a kinde of impetuous violence. If it be objected that seede is thicker then arteriall blood which yet hath need of a conspicuous canell or pipe to passe in as are the arteries: I answer, that the arteriall blood is a plentifull streame ordaind to water the whole body with a continuall and abundant influxion, which could not bee without very patent and open passages; so Nature formed the arteriall veine large and ample, that it might be sufficient to nourish the Lungs, a rare body and in continuall motion. But the seede falleth by degrees and insinuateth it selfe rather then floweth into the spermatike vessels, and is first prepared in their circumuolutions and after is deriued through small pores and hairy passages into the substance of the Testicles, and is thence driuen into the eiacularie vessels which are indeed porous as an Indian Reede, but haue no sensible cavity at all. There is not therefore required any such rectitude and amplitude in the vessels or substances conteyning the seede as *Aristotle* dreamt of, either for the concoction or eiaculation and auoyding thereof.

Arguments a-
gainst *Aristot.*

But let vs presse *Aristotle* a little farther, although the Testicles doe hang in their due place, yet doe those men become lesse apt for generation who haue their Testicles bruised or worne and wasted or refrigerated, so that euen thence it is manifest that their chiefe vse is not to stretch or dilate the vessels: besides many creatures haue their Testicles within tyed to their backs, and yet are as fruitfull as any other; as some Tuppes or Rammes called Riggall Tuppes, and all female creatures who are very prolifike though their Testicles hang not at all. Furthermore if the Testicles were made as waights to keepe the passages open; then in the time of coition or generation and eiaculation of seede the Testicles should descend downward that the passages might bee made more patent and open: but we finde the quite contrary to be true, that in coition the Testicles are contracted & drawn vpward, not let lower downward. *Aristotles* nice conceited vse therefore is but supposititious & not the true vse of Nature. *Auerrhois* being not able to auoyde the strength of these reasons, departeth from *Aristotles* opinion to whome he was so much addicted, and yeeldeth that the Testicles haue power to procreate seede.

Confutation
of the 2. vse.

The second vse ascribed to the Testicles by *Aristotle*, is for the tension and strengthening of the heart, to which we answer: that they bee of small waight, neither doe they hang at the heart vnlesse it be by arteries, and those not right but oblique, and yet those adhearing and tyed to the neighbour partes so as the Testicles cannot by them stretch or bend the heart: againe if this were a vse truly assigned, then their hearts and vigor should be strongest whose Testicles are more relaxed and hung lower: but women finde these much more impotent, and account them lazie loyned fellows: adde hereto, that if the heart needed any tension, it might better haue beene tentered, and with shorter stringes to the spine of the backe; also the Liuer is very neare and a waighty body, and tyed to the heart by the hollow veine, and therefore certainly stretcheth it more then the smal bodies of the Testicles placed so farre off and so slenderly depending vpon it, and that by stringes fastned to the backe by the way: moreouer the vessels which leade to the Testicles are diuersly contorted, and if they were stretched out woulde reach vnto a mans feete almost; againe, all creatures whose Testicles are hidde within should be faynt and crauen-hearted. Finally if this were true, the heart which is a most noble part should haue his strength not of himselfe but by dependency from else where, which were a great absurditie in reason. Wherefore we think this opinion of *Aristotles* to bee but a quaint deuice, worthy of the wit but not of the iudgement of so great a Philosopher.

Confutation
of the last vse.

As for the last vse assigned by *Aristotle* which is the erection of the yarde, that may be confuted by that we haue sayd before to be the true cause of erection, and that is partly Natural, to wit, an abundance of winde and spirits filling the hollow Nerves; and partly Animal,

small, from an appetite moving the muscles which are appoynted to make this erection. We will therefore bid adue vnto *Aristotle* his faigned conceite, and to them also who deny vnto the Testicles the power of procreating feede: for whereas they obiekt that there are many creatures which haue no Testicles and yet doe abound with feede prolifique or fitte for generation: wee answere that such Creatures are imperfect and their generation not perfect but lame.

To conclude, that a new gelt Horse or Bull can copulate and ingender seemeth hard to be beleued, because of the extreame payne that must necessarily follow the violation of parts of so exquisite sence; but if it do so come to passe, then is it by that seed that is already laboured by the ingenit power of the Testicles before they were separated, and reserued for present vse in the *Parastate* and *Prostate*; and not by any seed concocted after the taking away of the Testicles.

QUEST. III.

The opinion of Physitians concerning the true vse of the Testicles.

Here are some not vnlearned Physitians, who will not allow to the Testicles any power of procreating feede, but reserue that onely for the preparing vessels and the *Epididymis*; because there appeare no passages by which the seed should passe from the bunching implications of the vessels into the Testicles: againe the *Epididymis* and the preparing and leading vessels may be separated without rending from the Testicle: adde hereto that the *Epididymis* is often full of white feede, which is rarely found in the Testicle it selfe. They therefore say that the Testicles were made to sucke away the serous humour and excrement of the seed and to conteyne it, for which reason their substance is glandulous.

The opinion
of some Phy-
sitians.

Their reasons.

What vse
they assigne
to the testicles.

Now *Hippocrates* assigneth this vse to Glandules to receiue the excrements of the parts, & therefore the Braine, the Heart, and the Liuer, haue their seuerall Emunctories. But for my owne part I see no reason why the excrement of the seed should rather passe into the substance of the Testicles then the seed it self, which is so hoven and barded as it were with spirits: besides the body of the Testicles is rare and spongy, and hath many small pipes inserted into them out of the vessels; wherefore through these smal and almost insensible passages, they sucke the feede by an ingenit faculty of their owne; for if Aliment be brought vnto them to nourish them, and yet there are no conspicuous vessels disseminated through their substance, I see no reason but seed also may without manifest vessels be conueyed into them. Their bodies are indeed glandulous or resembling Glandules, but very Glandules they are not, as is sayd already. The third opinion concerning the vse of the Testicles is theirs who thinke, that they are ordayned for Pillowes to safe-gard and strengthen the vessels. For say they where there is any notable partition of vessels in the whole body, there Nature hath appoynted glandules as pillowes to secure them. So is the *Pancreas* placed vnder the diuision of the *vena porta* or Gate veine, many glandules are in the diuications of the veines of the mesentery: the *Thymus* vnder the *subclavian* diuision, and vnder the axillary and crurall veines notorious glandules or kernels are to bee found: in like manner the Testicles are appointed for the security of the spermatieall vessels. But the truth is that the onely ignorance of Anatomy brought in this old wifes fable. For the kernels or glandules which are placed at the diuisions of the vessels, do on euery side sustaine, establish and support them; but the Testicles are hung only at the ends of the vessels.

Answer to
them.Another opi-
nion.Which igno-
rance of Ana-
tomy hath
brought forth

Wherefore the opinion of *Hippocrates*, *Galen* and almost of all the Physitians is much more probable, who doe attribute to the testicles a power of their owne to procreate seed, and the prime place in the worke of generation, because they haue a great power for alteration of the habit, the temperament and the manners themselves. Moreover those creatures who haue abstained long from the worke of generation, haue their Testicles swolne and distended with feede, which vpon the vse of the Female doe abate againe. Which thing also *Aristotle* himselfe hath left testimony of where he sayeth: That certaine Birds and Beastes at what time they vse to couple, haue their Testicles very great, but when that season is over, they become so small that it may be doubted whether they haue any Testicles at all or no: and againe when the Testicles are refrigerated or ouer-cooled, then barrennes followeth. And truly

The true opi-
nion of almost
all Physitians.

Their reasons.

Diuerse in-
stances,

truely if a man list to runne ouer all the concoctions in the body of a man, hee shall finde that there is onely a preparation in the vessels, but concoction and perfect elaboration to be in and from the particular substance of the part.

The Animall spirit as we shall declare hereafter, is prepared in the wonderfull implications and texture of the arteries, but his forme and proper difference it acquireth in the marrowy substance or ventricles of the braine. The Milke is prepared in the veines but groweth white in the glandules of the Breaſtes. Blood getteth a kinde of rudiment in the veines of the mesentery, but his rednesse and the forme of blood it onely obteyneth in and by the *Parenchyma* or substance of the Liuer.

The true
course of the
seede.

In the small and threddy veynes of the particular parts there is a preparation vnto the third concoction, but assimilation is onely made by and in the substance of the parts. So there is a delineation and preparation of seede in the spermatike vessels, which are diuersly implicated by a wonderfull artifice of nature, that in those implications the spirits might be exactly mingled with the blood, and therefore here an artery entreth into a veine, and there a veine into an artery. The seede thus prepared the Testicles draw for their nourishment, to which they giue forme, perfection and foecundity, wherewith when they are satisfied, the remainder they expell into the leading vessels: these doe exonerate themselves into many small bladders, and into the *Prostate*, and there it is reserued and kept in store for the necessary vse of Nature in Procreation.

QUEST. IIII.

Of the substance and coates of the Testicles.

That the Te-
sticles are not
glandules.
The difference
betweene a
glandule and
a glandulous
body.

He substance of the Testicles some say are Glandules, allcading *Galen*, who reckoneth them among the Glandules in his third Booke *de Alimentis*: and *Hippocrates* in his Booke of Glandules defineth them to be spongy, rare, fatte and friable; but such are the Testicles, therefore they are Glandules. We answer that we must distinguish betweene Glandules and glandulous bodies. The Testicles are indeede glandulous bodies, so are the Kidneyes, so is the Braine, yet no man will call it a Glandule, but the body of it is like a Glandule, as wee shall shew more at large when we speake of the Braine.

Of their coat.
How many
coates stones
haue.

*Varicozum cor-
pus.*

Againe, concerning the coates of the Testicles, Anatomists doe differ one from another, some make more, some fewer: we resolue they are foure; two common and two proper: the two common are called *scrotum* or the Cod and *darton*: the two proper called *Eleutheroides* the first, & *Varicozum*, that is, the neruous membrane the latter *Vesalius* calleth this *Epididymida*, but *Falopius* elegantly confuteth him; for the *Epididymis* is indeede that we call *Parastata*, and is a body nota membrane, a little Testicle not a coate of the Testicle as the word signifieth: euen as a Cuticle is a small skinne; the *Epiglottis* a small tounge as it were. And *Galen* in the 15. and 16. Chapters of his Booke *de semine* calleth the *Epididymis* a particle fixed to the head of the Testicle, which wee haue seene to swell notably, the Testicle it selfe not being taynted at all, yea, and many *Epilepti*all fittes to arise therefrom.

The Testicles of women haue not this additament, or if they haue it is so smal that it cannot be perceiued. The reason may be because it was not necessary that their seede should be so laboured or thicke as that of mens, but remaineth more moyst and fluid, as it were to temper the action of the seede of man.

QUEST. V.

Of the consent betweene the Chest and the Testicles.

The consent
betweene the
Chest and the
testicles.
Three places
of Hippocrates
expounded.

HE Consent betweene the Chest and the Testicles is expressed by *Hippocrates* in three seuerall places. In the first Section of the second Booke *Epid.* he sayeth, *When the Testicle swelleth after a Cough, it calleth to our remembrance the consent or sympathy betweene the Chest, the Breaſts, the Seede and the Voice.* Againe, in the first Section of the first Booke thus; *Many were overtaken with dry Coughes, and many of those men long after were troubled with painful inflammations, sometimes in one stone, sometimes in both.* Thirdly, in the first againe of the second Booke thus: *Long and inueterate Coughes doe cease when the Testicles begin to swell.* Howe this commeth to

What Hippo.
meaneth by a
dry cough.

pasle

pasſe we will now declare: but firſt it muſt be reſolued what that diuine old man meant by dry Coughes; not that Cough which is without matter; cauſed either by a bare diſtemper as when the winde is at the North, or by the inequality of the rough Artery, or by the ſympathy of the ſinnewy parts, for how could that breede tumors and Apoſtemations? But a Cough with a matter, whoſe cauſe is either the thinneſſe of the matter, which the breath cannot intercept as we cough, but it ſlideth downe by the ſides of the weazon; or elſe the thicknes of the ſame which will not follow the conſtraint of the cheſt. This matter whether thin or thicke Hippocrates vnderſtandeth to be euacuated by Apoſtemations belowe, and eſpecially in the coddies or teſticles: but all the difficulty is, which way this crude matter ſhould paſſe out of the cheſt vnto the parts of generation.

There are threee ſorts of veſſels which goe to the Teſticles; A Nerue, an Artery, and a veine, all which haue through-paſſages from the cheſt to the teſticles. Firſt of all, a notable and euident branch of the rib ſinnew called *Coſtalis*, runneth by the ſides of the ribs into the Teſticles. A veine from the *non-parill* or vn-mated veine of the breſt runneth thorough the Midriffe, and determineth into the veine of the Kidney, and the ſpermatieall veines. As for the Artery, albeit none do come to the great trunk from the Lunges (in whoſe lappes the matter of the cough doth lye) yet it is not vnreaſonable to thinke that the offending humour may paſſe by the venall artery into the left ventricle of the heart, and from thence into the great artery, & ſo into his branches; by which way alſo the matter or *pus* of *pleuriticall* and *Peripneumonicall*, or *Empyricall* patients deſcendeth, and ſo is diuerſly auoyded by vrine, ſeidge, or Apoſtemations in the lower parts; and by this paſſage alſo it is more then probable, that the matter ſhould fall out of the cheſt to the teſticles.

The wayes by which the humor muſt paſſe out of the cheſt into the teſticles.

The way of the nerue.

The way of the Veine.

The way of the Artery.

The paſſage of matter thorough the left Ventricle of the heart.

QUEST. VI.

Of the ſituation of the Proſtate.

Concerning the Glandules called *Proſtate*, Anatomists doe contend; ſome thinke they are placed beneath the ſphincter Muſcle, others aboue, we adhere to the latter. For, beſide the credite of diſſection, if they were placed below the ſphincter then the ſeede ſhould neuer be ſpent without the auoyding of vrine alſo, and againe in the running of the reines, the ſeede could not flow without the water; beſides the Vrine would alwayes lye vpon theſe Glandules and fret them with his acrimony. They are therefore placed aboue the ſphincter, and their inflammation or exulceration breeds the venerious gnorrhæa or running of the reines.

That the Proſtates are aboue the ſphincter.

QUEST. VII.

Whether the Erection of the yard be a Naturall or an Animall action.

Very action according to *Galen*, is Naturall or Animall; that he calleth Naturall which is not voluntary, ſo the vitall faculty is Natural becauſe it is not Arbitrary. The inflation of the virile member is an action, becauſe there is in it Locall and Mathematical motion, it muſt therefore needs be a Natural or an Animal, or a mixt action.

How many ſorts of actions there are.

That erection is meere Animall.

To prooue it to be meere Animall this argument is vrged, becauſe all the Animall faculties, Imagination, Motion, and Senſe do concur to the perfection of it. For the firſt, before the diſtention of this part, whether we wake or ſleepe, wanton and laſciuious imaginations do trouble vs. Now mens Imaginations when they wake are alwayes voluntary and arbitrary with election, & when they ſleepe, then are their imaginations like thoſe of brute beaſts, following the ſpecies or Idea and representations of the ſeede as it pricketh and ſwelleth theſe parts of generation. For euen as in ſleepe Flegme ſtirreth vp in our imaginations ſimilitudes of raines and waters, Choler of rage and fury like vnto it ſelfe, Melancholy that enemy of the light and demolisher of the principles of life it ſelfe, powreth a cloude of darkneſſe ouer our minde, and repreſenteth to our imaginations ſimilitudes full of terror and feare: right ſo the ſeede contained in the *Proſtate* ſwelling with abundance by his tickling,

The effects of the humors in ſleepe.

How veneri-
on imaginati-
ons in sleep are
moued.

tickling or itching quality communicated to the braine by the continuity of the sinnewes, moueth or stirreth vp images or shaddowes of venerious delights in the fantasies of men, wherefore this part or member is not erected without the helpe of the imagination.

The Sense moueth the imagination, the imagination commandeth the mouing Faculty, that obeyeth, and so it is puffed vp. The mouing Faculty hath the help of four Muscles, two of which run a long the sides of the member; now wee know that all motions of the Muscles is Animall, because a Muscle is defined to be an instrument of voluntary motion. This inflation hath pleasure also ioyned vnto it, but pleasure is not without sence; wherefore all these three Animall faculties concur in erection, and therefore it is meerly an Animall action.

That it is
meerly natu-
rall
The instru-
ments.

The efficient.

The finall.

The middle &
true opinion
that it is a mixt
action.

Comparison
from the ap-
petite.

On the contrary that it is a Naturall action may thus bee demonstrated: all the causes of his distention, the instruments, the efficient and the end are Naturall. The Naturall organs or instruments are two ligaments, hollow, fungous and blacke, which though they be called Nerues, yet are not voluntary and sensible or feeling sinnewes; they arise from the hanch and share-bones, not from the brayne or marrow of the backe. The efficient cause is not our will, because erection is not alwayes at our commaundement either to moue or to appease as we may doe our armes, legges and eyes; but the efficient cause is heate, spirites and winde, which fill and distend these hollow bodies, with an infinite number of vesselles both veines and arteries dispersed and wouen through them. The finall cause is procreation which belongeth to the Naturall not to the Animall faculty.

Betwixt these two extreames we wil take the middle way and determine, that the action of erection is neyther meerly Animall nor meere Naturall, but a mixed action. In respect of the imagination and the sence it is Animall, because it is not distended vnlesse some luxurious imagination goe before, and the distention when it is made is alwayes accompanied with a sence of pleasure and delight; but in respect of the motion we rather thinke it to be Naturall which yet is somewhat holpen by the Animall. For as the appetite which is stirred vp in the vppermost mouth of the stomacke (because traction breedes diuulsion, diuulsion sence, sence Appetite) is called Animall; and yet the motion wherby the greedy stomack sometimes snatcheth vnchewed meate euen out of the mouth is Natural: so the erection of this member because it is with sence and imagination is sayed to bee Animall, but the local motion whereby it is mathematically enlarged is Natural, arising from the inbred faculty of the ligaments: such is also the motion of the wombe when it draweth seede, and of the heart when it draweth into it selfe ayre and blood. Yet it must be confessed that this natural motion is holpen by the Animal, because the foure muscles before mentioned though they be very small, yet they helpe to enlarge the distention, and doe also for a time keepe it so distended.

Obiection.

Solution.

Comparisons.

Priapismus.

The causes of
it.

Melancholy
men subiect to
it and why.

If it be obiected that in the running of the Reynes called the venereall *Gonorrhoea*, there is erection without imagination or pleasure, yea with payne. I answer with *Galen* that there is a twofould erection, one according to nature, another vnnaturall; the first is from the ingnit faculty of the hollow ligament; the other is symptomaticall; the first with pleasure, the other without it yea with payne; in the first the yarde is first distended and after filled with a vaporous spirite; in the latter it is first filled then after distended. In a word, there is the same difference betweene these two distentions which is betweene the two motions of the heart. In the Natural motion of the heart which is accomplished by the vital faculty, because the heart is dilated it is filled with ayre and blood, and because it is contracted it is emptied; but in the depraued palpitation of the heart the heart is distended because it is filled. So smiths bellows because they are dilated are presently filled with ayre for the auoyding of vacuity, but bottles are distended because they are filled with wine or water.

Wherefore the Naturall erection euer followeth imagination and hath pleasure accompanying it, but the vnnaturall which *Galen* calleth *Priapismus*, is altogether without lust or appetite. The cause of this is a plenitude of thicke and crasse wind, proued because the motion is so sudden and so violent; for all violent and sudden motions are of winde not of humor as *Galen* saith; and this wind or vapour is generated either in the hollow nerues and ligaments, or is thither brought by the open passages of the arteries. But of what? Surely of crasse and thicke humours, and that is the reason why melancholly men are most troubled with this vnnaturall erection; as also are Lepers, and therefore the Ancients called the Leprosic *Satyriasis*. And thus much concerning the parts of generation in men, now it followeth concerning those of women.

QUEST. VIII.

How the parts of generation in men and women doe differ.

CONCERNING the parts of generation in women, it is a great and notable question whether they differ onely in situation from those of men. For the ancients haue thought that a woman might become a man, but not on the contrary side a man become a woman. For they say that the parts of generation in women ly hid, because the strength of their naturall heate is weaker then in men in whom it thrusteth those parts outward. Women haue spermaticall vessels, aswel preparing as leading vessels & testicles which boile the blood, and a kinde of yard also, which they say is the necke of the wombe if it be inuerterd. Finally, the bottome of the womb distinguished by the middle line, is the very same with the cod or *scrotum*. This *Galen* often vrgeth indiuers of his works as before is saide; so *Agineta*, *Anicen*, *Rasis*, and all of the Greeke & Arabian Families, with whom all Anatomists do consent. For confirmation also heereof there are many stories current among ancient and moderne writers of many woemen turned into men: some of which we will not heere thinke much to remember. First therefore we reade that at Rome when *Licinius Crassus*, and *Cassius Longinus* were Consuls, the seruant of one *Cassius* of a maide became a young man, and was thereupon led aside into the desert Island of the Sooth-sayers. *Mutianus Licinius* reporteth, that at *Argos* in Greece, he saw a maide named *Arescusa*, who after she was married became a man and had a beard, and after married another woman by whom she had yssue.

Pliny also writeth, that he saw in *Affrica* *P. Cossitius* a Citizen of *Tisdetra*, who of a woman the day before became a man the next day. The *Hyena* also a cruell and subtile beast, doth euery other yeare change her sexe. Of whom, *Ouid* in the 15. of his *Metamorphosis* saith.

Et qua modo femina tergo

Passa marem, nunc esse marem miramur Hyenam.

The same *Hyena* which we saw admit the male before,

To couer now her female mate, we can but wonder sore.

Pontanus hath the same of *Iphis* in an elegant verse:

Vota puer soluit que femina voverat Iphis.

Iphis her vow benempt a Maide,

But turned boy her vow she paid.

Of later times. *Volateran* a Cardinall saith, that in the time of Pope *Alexander* the sixth he saw at Rome a virgin, who on the day of her mariage had suddenly a virile member grown out of her body. We reade also that there was at *Auscis* in *Vasconia*, a man of aboute sixtie yeares of age, grey, strong and hairy, who had beene before a woman till the age of 15. yeares, or till within 15. yeares of threescore, yet at length by accident of a fall, the Ligaments (saith my Author) being broken, her priuities came outward, and she changed her sex; before which change she had neuer had her courses. *Pontanus* witnesseth that a Fishermans wench of *Caieta* of fourteene yeares olde became suddenly a young springall. The same happened to *Emilia* the wife of *Antonie Spensa* a Citizen of *Ebula*, when she had beene twelues yeares a married woman.

In the time of *Ferdinand* the first K. of *Naples*, *Carlota* and *Francisca* the daughters of *Ludouiske Quarna* of *Salernum*, when they were 15. yeares old changed their sex. *Amatus Lusitanus* testifieth in his Centuries that hee saw the same at *Conibrica* a famous towne of *Portugall*. There standeth vpon record in the eight section of the sixth Booke of *Hippocrates* his *Epidemia*, an elegant History of one *Phaetusa*, who when her husband was banished was so ouergrown with sorrow, that before her time her courses vtterly stopped and her body became manlike and hairy all ouer, and she had a beard and her voice grew stronger. The same also he recordeth to haue hapned to *Namisa* the wife of *Gorgippus* in *Thaso*.

Wherefore say they, if a Woman may become a man and her parts of generation which before lay hid within may come foorth and hang as mens do, then do women differ from men onely in the scite or position of their parts of generation.

Notwithstanding all this, against this opinion there are two mighty arguments: one is taken from the *avro-ia* in dissection, another from reason, which two are the Philosophers Bloud-bounds, by which they tract the causes of things.

For first of all (saith *Laurentius*) these partes in men and women differ in number. The small bladders which first *Herophilus* found, and called *varicosos adstites*, that is, the *Parastata*

stata, women haue not at all; nor the *Prostata* which are placed at the roote of the yard and necke of the bladder, in which seede is treasured vp for the necessary vses of nature; althogh there be some that think that women haue them but so sma! that they are insensible, which is (saith he) to begge the question. Againe, me thinks it is very absurd to say, that the neck of the wombe inuerted is like the member of a man; for the necke of the wombe hath but one cauity, and that is long and large like a sheath to receiue the virile member: but the member or yard of a man consisteth of two hollow Nerues, a common passage for seede and vrine, and foure Muscles. Neyther is the cauity of a mans yard so large and ample as that of the necke of the wombe. Add to this, that the necke of the bladder in women doth not equall in length the necke of the womb, but in men it equalleth the whole length of the member or yard. Howfoeuer therefore the necke of the wombe shall be inuerted, yet will it neuer make the virile member: for three hollow bodies cannot be made of one, but the yard consisteth of three hollow bodies; two Ligaments arising from bones and the *epididyma*, as we haue before sufficiently shewed. If any man instance in the *Tentigo* of the Ancients, or *Fallopian* his *Clitoris*, bearing the shape of a mans yard, as which hath two Ligaments and foure Muscles, yet see how these two differ. The *Clitoris* is a small body, not continued at all with the bladder, but placed in the height of the lap, the *Clitoris* hath no passage for the emission of seede; but the virile member is long and hath a passage in the midst by which it powreth seede into the necke of the wombe.

Neither is there (saith *Laurentius*) any similitude betweene the bottome of the wombe inuerted, and the *scrotum* or cod of a man: For the cod is a rugous and thin skin, the bottome of the wombe is a very thicke and thight membrane, all fleshy within and wouen with manifold fibres.

Finally, the insertion of the spermatick vessels, the different figure of the mans & womans Testicles, their magnitude, substance and structure or composition doe strongly gainsay this opinion.

But what shall we say to those so many stories of women changed into men? Truly, I thinke saith he, all of them monstrous and some not credible. But if such a thing shall happen, it may well be answered that such parties were Hermaphrodites, that is, had the parts of both sexes, which because of the weakenesse of their heate in their nonage lay hid, but brake out afterward as their heate grew vnto strength. Or we may safely say, that there are some women so hot by nature that their *Clitoris* hangeth forth in the fashion of a mans member, which because it may be distended and againe growe loose and flaccid, may deceiue ignorant people. Againe Midwives may oft be deceiued because of the faultie conformation of those parts, for sometimes the member and testicles are so small, and sinke so deepe into the body that they cannot easily be discerned.

Pitatus writeth, that at *Paris* in the yeare, 1577. in the streete of *S. Denis*, a woman trauelled and brought forth a sonne, which because of the weaknesse of the infant was suddenly baptized for a daughter, and was called *Ioanna*. A fewe dayes after, in dressing the Infant the Mother perceyued it to be a manchild and so did the standers by and they named it *Iohn*.

As for the authority of *Hippocrates*. It followeth not that all those women whose voyces turne strong or haue beards and grow hairy do presently also change their parts of generation; neither doth *Hippocrates* say so, but plainly the contrary: for he addeth, *when we had tried all meanes we could not bring downe her courses, but shee perished*. Wherefore hir parts of generation remained as those of a Woman, although her bodye grew mannish and hairie.

QUEST. IX.

Of the motions of the wombe.

ANOTHER question there is, whether the wombe moue locally and Mathematically, or Physically onely: concerning which we will resolue thus. There is a threefold motion of the womb, one altogether naturall, another altogether symptomaticall and Convulsive; the third mixt, partly Naturall partly Symptomaticall. The Naturall motion is meere from the faculty of the soule; the Symptomaticall meere from an vnhealthfull cause, the third from them both together.

The

The naturall motion is when the wombe draweth seed out of the neck into his bottome, for then it runneth downward to meete it, insomuch that sometimes it hath beene scene euen to fall out; it mooueth also naturally when in conception it is contracted and imbraceth the seede strictly on euery side; as also when it excludeth the Infant, the afterbirth or any other thing containd in it beside Nature. For the accomplishment of this motion it hath right fibres and very many transuerse or ouerthwart, and this motion comes from the necessity of Nature.

The naturall motion of the wombe.

The symptomaticall motion is onely from a cause that is morbus or diseasful and that is convulsive; which motion is manifest in the suffocation of the matrix, for then the womb is moued vpward because it is drawne convulsively; and that comes either from repletion or from exhaustion or emptines, the ligaments either being by drought exsiccated or steeped in ouermuch moysture: sometimes it commeth from a poysonous breath, from the suppression of the courses, or the retention and corruption of the womans seede false into it out of the vessels.

The symptomaticall motion of the wombe. The suffocation or strangulation of the matrix.

In this convulsive motion the midriffe is pressed or borne vp, which is the chiefe instrument of free respiration or breathing, and the braine is also drawn into consent, which is the chiefe seate or tribunall of the Animall faculty, which faculty is the efficient cause of respiration. Hence it is that in such suffocations or strangulations there is an interception of respiration, for the instrumentall cause the midriffe is intercepted, so is the efficient cause the Animall faculty also, because the braine is drawne into consent. The finall cause also is taken away, for the heat of the heart at that time is very small and requireth therefore no other ventilation but by transpiration, which is by the pores of the habit of the body.

Why such women do not breathe.

All the causes of respiration in this suffocation are taken away.

But you must marke that I call not this motion a convulsion, but onely a convulsive motion; for convulsion properly is, an vnbidden motion of those parts which we vse to moue at our commandement, but the wombe is not moued by our willes but by it owne will, wherefore convulsions belong not to the wombe but to the muscles onely which are instruments of voluntary motion; but abusively we may call this a convulsion as Hippocrates calleth the Hiccocke a convulsion.

What parts suffer convulsions.

The third motion of the wombe wee sayed was mixt, proceeding partly from a morbus or vnhealthy cause and partly from the faculty, as in a great exiccation it runneth vpward toward the Liuer which is the fountaine of sweete moysture; for all dried partes doe as it were thirst after this moysture with a naturall appetite; and this motion is indeede truly mixt, being partly physicall or naturall, the dry wombe drawing toward the seate of moysture, or drawing the moysture vnto it selfe as Galen interpreteth it; and partly mathematicall or locall; it moouing as Hippocrates sayeth, with a kinde of impetuous violence to the *precordia*; although I am not ignorant that Galen in this poynt reprooueth his maister, and taketh this motion to be meere Physicall or naturall; and called mathematicall by Hippocrates but abusively onely.

The 3. mixt motions of the wombe.

QUEST. X.

How the wombe is affected with smells and saours.

Furthermore it is not onely recorded by ancient Authors, but approued by daily experience, that the wombe is much affected with saours and smells; so that some haue beene knowne to miscarry vpon the stench of a candle put out as Aristotle recordeth in his 8. Booke of the History of Creatures and the 24. Chapter. But how and by what passages this apprehension of odours is, few haue sufficiently declared; wherefore we will payne our selues a little and our readers also, to lay open this difficulty, because it may be of great vse for the preservation of health, and will not be altogether vnpleasant to them that desire to know themselves.

How the wombe is affected with smells & saours.

As therefore Colour is the onely obiect of the sight, so is odour of the smelling; and as the sight hath the eye as his peculiar and proper instrument of seeing, so is the nose (I mean principally the parts containd within it, that is, the spongy bone and the two processes called *mamillares*) the only instrument of smelling: it were therefore very absurde to imagine that the wombe did smell saours or smells as we call them, because it is not the proper instrument of smelling, how then? It is affected with saours by reason of the subtile

and thinne vapour or spirit which ariseth from any strong sented thing; euen as our spirits are refreshed and exhilarated with sweete sauours, not by apprehending the sent of them; but by receiuing a thinne ayrie vapour from them whereby the spirits are nourished, enlightened and strengthened; right so is the wombe affected with the vapors of things which yeelde a strong smell be it pleasant or vnpleasant, and that very suddenly, because it is a part of exquisite sence. But if it bee so, it may be demanded, why then the wombe is pleased with sweet smells and displeased with those that are vnpleasant? for it seemeth hereby to make choyce of smells euen for the very saueur and sent. I answer that all things which yeeld a noysome smell are vnconcocted and of a bad or imperfect mixture, and therefore they affect the sence with a kinde of inæquality; or else the spirits or vapors that arise from these ranke bodies are impure (whence come faintings and swooundings sometimes,) and so defile the spirits containd in these generatiue parts.

One difficulty there yet remayneth. If the wombe delight in sweete sauours, why then doth the smell of Amber greece, muske and such like bring suffocation of the mother; and that of *assa fetida* and *castoreum* and such like extreme stinking things cure the same disease? I answer, that all women fall not into suffocation vpon the smelling of sweet perfumes or the like, but only those whose womb is especially euilly affected. For sweet smells hauing a quicke spirit arising from them, doe instantly affect the Braine and the membranes of the same, the membranous womb is presently drawne into consent with the Brayn and moued, so as those bad vapors which before lay as it were asleepe in the ill affected wombe, are now stirred and wrought vp by the arteries or other blinde passages vnto the midriffe, the heart and the braine it selfe, and so comes the suffocation we spake of. But those things that yeeld a noysome saueur, because they are crude and ill mixt, doe stoppe the passages and pores of the braine, and do not reach vnto the inner membranes to affect them: they cure also the *Hysterical paroxisme* or fitte of the mother, because our nature being offended with them as with enemies rowseth vp it selfe against them, and together with the ill vapors excludeth also out of the wombe the euill humors from whence they arise, euen as in acute diseases nature being prouoked by the ill quality of the humors moueth to criticall excretions, or in purgations when she is goaded with the aduerse quality of the medicine relieueth her selfe by euacuation.

But you will aske by what passages are these vapors and spirits carried? I answer, beside the open passages of the Arteries by which such ayrie spirits doe continually passe, and repasse, in a mans body there are many secret and vknown waies which those subtile bodies may easily finde, considering that euen crasse and thicke humours doe ordinarily follow medicines we know not by what passages; as when a little *Elaterium* euen a graine or two will purge away three or foure pintes of water or more which lay before in the capacity of the *Abdomen*, drawing it thence into the gutts, and yet we know no direct passages from the one part to the other; and this hath made men to say that as open as the body of glasse is to the light although it be very solide, so open is the whole body as to externall aire of which we finde our body oftentimes very sensible, so to humours, much more to spirits and thinne and subtile vapors. Experience hereof we haue in the vse of Tobacco, for a man shal often finde it sensibly in his toes and fingers ends presently vpon the taking.

But of this we shall take leaue in the next discourse to speake a little more largely seeing it not onely concerneth almost all women, but may serue somewhat to stay their minds vpon many accidents which euery day befall them.

QUEST. XI.

Of the wonderfull consent betweene the wombe and almost all the parts of womens bodies.

An enumerati-
on of the parts
with which
the wombe doth
sympatize.

Concerning the wonderfull sympathy that is betweene the womb and almost all the parts of womens bodies, that place of *Hippocrates* in his Booke *de locis in homine* is most remarkable, where he sayeth, *That the wombs of women are the causes of all diseases*: that is to say, The wombe being affected there follow manifest signes of distemper in all the parts of the body, as the Brayne, the Heart, the Liuer, the Kidneyes, the Bladder, the Gutes, the Share-bones: and in all the Faculties, Animall, Vitall, and Natural;

rall: but above all, the sympathy betweene the wombe and the breastes is most notable, yet will we not sticke a little to insist vpon the former particulars.

Betweene the Brayne and the wombe there is very great consent, as well by the nerves as by the membranes of the marrow of the backe: hence in affects of the Mother come the paynes which some women often fee in the backe-parts of their head, their frenzies or franticke fittes, their dumbe silence and indeede inabilityie to speake, their strange fearefulness, sometimes loathing their liues, yet fearing beyond measure to die; their convulsions, the caligation or dimnesse of their sight, the hissing of their eares, and a world of such like and of vnlike accidents.

Betweene the heart and the wombe the consent is made by the mediation of manie notable Arteries called Spermaticall and Hypogastricall, that is, the Arteries of seede, and of the inferiour part of the lower belly. Hence come light faintings, desperate swoonings, the cessation of breathing and intermission of the pulse at least to the feeling, the vse of them both being taken away by a venemous breath, which dissolueth the naturall heate of the heart; and such women liue onely by transpiration, that is by such aer as is drawne through the pores of the skin into the Arteries & so reacheth vnto the heart: so that it is impossible almost to perceiue whether such women do yet liue or no, and doubtlesse many are buried in such fits (for they will last sometimes 24. houres or more, and the bodies grow colde and rigid like dead carcases) who would recouer if space were giuen.

In my time there went a woman begging about this Cittie, who had a Coffin carried with her, and oftentimes she fell into those Hysterical fits, and would lye so long in them, nothing differing from a dead carcas, till the wonted time of her reuiuing. Hence it may be came the Prouerbe, *Thou shalt not beleue a woman (that shee will die) no not when shee is dead,* till she be buried.

This is a sore accident, and therefore it shal not be amisse to tel you how you may know whether such haue any life left in them or no. A downy feather applyed vnto their mouth will not sometimes serue the turne, for you shal not perceiue it to shake and yet the woman liues; the onely infallible token of life or death, is if you apply a cleare looking glasse close vpon their mouths, for then if they liue the glasse will haue a little dew vpon it, if they be dead none at all. But the safest way is not to be ouer-hasty to burie women, especially such as dye suddenly and not vpon euident cause, till 2. or 3. dayes bee ouer, for some haue beene knowne so long after their supposed deaths to reuiue, and some taken agayne out of their Coffins haue beene found to haue beaten themselues vpon their reuiuing before their stifling in the graue, if we will beleue the reports of such as we haue no great reason to mistrust. But to returne to our sympathy.

Betweene the Liuer and the wombe the sympathy is a little above expressed, to which we may adde, that as from other parts affected, so from the ill affection of the wombe, sometimes come laundises, Cachexies, that is, ill habits of the bodie, green sicknesses, and (then which nothing is more ordinary) the Dropsie it selfe.

Betweene the Kidneyes and the wombe the consent is euident in the torments and pains of the Loines, which women and Maides haue in or about the time of their courses. In so much as some haue told me they had as leefe beare a childe as endure that paine; and my selfe haue seene some to my thinking by their deportment, in as great extremity in the one as in the other. This consent commeth by the mediation of the spermaticke veines, for the left of these vessels ariseth out of the emulgent or kidny vein on the same side. The like may be said of the sympathy between the wombe the bladder & the right gut, for vpon inflammation of the wombe, as Hippocrates writeth in his first Booke *de Morb. mulier.* commeth the disease of the right gut, called *Tenesmus*, that is a vaine desire to empty the belly, and also the *Strangurie*, because the inflammation presseth both parts; so that neither the excrements nor vrine can be long kept.

This consent is by reason of the vicinity or neighbourhood of the parts, as also by communion. The communion is by the membranes of the *Peritonaeum* which tie the wombe to these partes, and by their common vessels, for from the same branch of the Hypogastricall Veine come small riuers to the bladder, the wombe and the right gut. Neyther is the Connexion of the wombe with the share-bone and the Leske to be ouer passed without remembrance, which is made by two exceeding strong Ligaments, for which cause in the suffocations of the matrix, we apply Cupping-glasses to the sides of the Share-bones and to the Leske, that by these Ligaments as by certaine cords the wombe labouring vpwarde may be retracted and drawn backe.

likely.

But aboue all other Consents is that sympathy betwene the wombe and the breasts which exceedeth euen admiration it self, and is diuersly manifested by the frequent translation of humors out of the breasts into the wombe, and out of the wombe into the breasts; by the signes of the wombe affected which are taken from the inspection of the breasts; from the vsuall cure of the diseases of both parts; and finally from the knowledge wee haue by the breasts of the condition of the infant yet containd in the wombe. Beside the authority of *Hippocrates* in his Booke de *Glandulis*, we haue many examples of the first, that is of the translation of humors too and againe betwene these parts.

Amatus Lusitanus in his second Century the second Cure reporteth, that hee saw two women, who vpon the suppression of their courses did auoid blood out of the Nipples of their breasts at certaine and set times and returnes, imagine shortly after the vsuall time of their courses. And *Hippocrates* it appeareth had seene the like, for hee writeth in the 40. Aphorisme of the fift section, that those women who haue blood gathered about their breasts are in danger to grow mad and raging. *Brassauolus* reporteth, that hee saw a woman out of whose breasts issued blood in stead of milke; and this may well be, for we all know that Nurses haue their courses stopped, because the blood returneth from the wombe vnto the breasts, where it is turned into milke vsuall; that in this example the blood came out vnturned was the rarity. We haue seene also on the contrary many women in childebed who haue auoided by the wombe and the bladder great quantities of milke. This translation of humors therefore is ordinary. Sometimes the blood goeth other wayes, as I haue knowne an ancient maide in Lincolnsire, who euer about the time she should haue her Courses, for many daies together hath found in her mouth in the morning when shee awaked, the quantity of three or foure ounce of blood more or lesse, and most part of it caked as it is in a Sawcer after blood-letting, and this continued with her for many yeares together, but hir teeth rotted fowly with it, her breath grew noisome, and shee faint at those times, but without any other disease.

For the second, that is, that by the inspection of the breasts the condition of the wombe may be knowne, we will alledge onely that oracle of *Hippocrates* in the sixt Booke of his *Epideemia* and the fift section. If the Nipples of the breast and that which is vsuall red about them, grow pallid or yellowish, then is the wombe diseased.

For the third, that the cure of the affectes of these parts demonstrate their sympathie, we may remember that which *Hippocrates* hath deliuered, and is continually put in practise as neede requireth, viz; *If you would stay the immoderate fluxe of a womans Courses, then set a great Cupping-glasse vnder her breast; for that will draw backe the blood by an accustomed way.*

Finally, by the inspection of the breasts, the age, the sexe, and the health of the Infant yet in the wombe is demonstrated. *Hippocrates* in his Booke de *Natura pueri*: *As soone as the infant beginneth to moue, the Milke acquainteth the Mother with it, for presently vpon the motion the breasts swell, and the Nipples strut out.* If therefore the breasts bewray the time of the infants mouing then doe they also declare the age; for a man childe moueth the thirde month, a maiden childe the fourth. And for the sexe, *If the right breast, saith Hippocrates in the 38. Aphorisme of the fift Section, doe consume or fall, it fore-tokeneth an abortment of a male childe; if the left, of a female; so if the right breast swell and strut it is a signe that a male childe is conceived, if the left a female.*

Last of all, the inspection of the breasts doth foretel the health or sicknesse of the infant. For if in a woman with childe the breasts do suddenly fall swampe as we say, then will shee abort ort miscarry, so saith *Hippocrates* in the 37. Aphorisme of the fift section. All these are most euident and necessary arguments of the consent and sympathy between the breasts and the wombe: but because almost all simple sympathies are made by the communion of vessels, we will in a few wordes lay open vnto you how the vesselles of the two partes doe communicate one with another, as *Laurentius* conceyueth it.

Almost all Anatomistes do agree, that the branches of the ascending Epigastrick veine, do meete in one with the branches of the descending Mammariæ veine; and that there are in these branches many Anastomoses or inoculations. I doe not deny (saith *Laurentius*) the coition or coniunction of these branches, but seeme to my selfe to haue found more patent large, and nigher wayes for this communion. For the Epigastricke veine is not disperfed in his branches through the wombe, but ariseth more commonly from a branch of the Cru- rall veine.

Lik-

Likewise that veine which they call *Mammaria* or the brest veine, runneth by the inner part of the brest-bone to nourish the Triangular Muscle, neither doth it send any branches to the brests vnlesse they be very smal and threddy. I suppose therefore (saith he) that blood, milke and other humours doe flowe backe by the Hypogastricke and spermaticall Veynes (which are proper veines of the wombe) vnto the trunk of the hollow veine, and out of it into the vein called *Axillaris* or the shoulder vein, from which there arise two notable chest veines called *Thoracicae*, which do water the Muscles of the chest, and the Glandules or kernels of the brest.

The Mammaria Veine.

The Hypogastrick & spermaticall Veynes.

On the other side, I conceiue that the milke returneth by the *Thoracicall* veines to the *Axillarie*, from it vnto the trunk of the hollow veine: from which it passeth sometimes by the spermaticke branch into the wombe; sometimes by the *Hypogastricall* partly into the wombe partly into the bladder; from whence come oftentimes those milky waters which wee call *Lactea*, that are made after the woman is deliuered. There is also a nearer way for the milke to passe by the wayes of the vrine through the emulgent veines.

Milky waters made after womens labour.

QUEST. XII.

Concerning the Acetabula, the hornes and coates of the wombe.

Concerning the endings of the vessels in the bottome of the wombe, to which the after-birth cleaueth till it be seuered either by the strength of the Infant, or after by the dexterity of the Midwife, they are called *Acetabula* in Latine; in Greeke *Coryledones*, which are nothing else but the ioyning of the endes of two paire of veines (one comming from the spermaticall another from the *Hypogastricall* branch) with the mouths of the vmbilicall veine; and so making a symphysis or connexion between the mother and the Infant.

Coryledones what they are.

The latter Anatomists deny that there are any such conspicuous in women, but onely in Sheep and Goates: *Aristotle* sayth (in his 3. Book of the *Historie* and the second of the *Generation of Creatures*) they are onely to be found in horned Beasts: we say, There is a 3. fould acceptation of this word *Acetabula* in *Galen*s Book of the dissection of the wombe. First they signifie visible holes into which the vessels of the wombe doe end in fashion resembling the hearbe called Venus Nauil, which we call in English Penny-grasse or hippewort. These *Acetabula* are neuer found in women but in Sheep & Goates are very conspicuous. Secondly by *Acetabula* we vnderstand the mouthes of the vessels swelling like Nipples. And lastly, they are the ends of the vessels at the bottome of the wombe ioyning with the vmbilicall or Nauill veines. In this third acceptation no man will deny but that they are to be found in the wombe of a woman.

In what Creatures they are found.

What *Galen* meaneth by *Acetabula*.

How they are to be found in women.

These mouthes of the vessels sayeth *Hippocrates* in the 45. Aphorisme of the fifth Section, if they be full of mucous or slimy water are the cause of abortment, because it dissolueth the continuity or connexion of the Infant with the wombe.

A cause of abortion.

Concerning the hornes of the wombe which bud out at the sides thereof, *Diocles* first of all men made mention of them. *Galen* and almost all Anatomists following him do confesse them to be in the wombe of a woman; but the truth is, that they are only conspicuous in Sheep, Goates, and Kine. Indeepe the sides of a womans wombe doe swell a little and are rayed where the leading vessels doe end, but not sufficiently to expresse the forme of horns or Nipples.

Of the hornes of the wombe.

Lastly, *Galen* seemeth to speake diuersly concerning the coates of the wombe, sometimes affirming it hath but one, as in the third Booke of *Naturall faculties*; againe in his Booke of the dissection of the wombe he sayeth it hath two; the outward peritoneous, the inward venal; the outward simple, the inward double; but these places may easily be accorded: for whereas he sayeth it hath but one, he vnderstandeth the proper coate of the wombe which is the thickest of all the coates of the body; but when he sayeth it hath two, he addeth to the proper a common coate comming from the *Peritoneum* or Rim of the Belly.

Of the coates of the wombe.

Galen reconciled to himselfe.

QVART. XIII.

Of the Membrane called Hymen, and the markes of virginity.

What the Hy-
men is thought
by some to be.

The locke of
virginity.
A custome a-
mong the
Iewes.

Laurentius his
opinion.

Imperforata
mulieres.

Actus. 4. cap. 28.
Paul. lib. 6.
cap. 73.
Celsus lib. 7.
cap. 28.
Albucasis lib. 2.
Oribasius lib. 2.
medic. lib. 2.

It hath beene an old question and so continueth to this day, whether there be any certaine markes or notes of virginity in women and what they are. Almost all Physitians thinke that there is a certain membrane sometimes in the midst of the necke of the wombe, sometimes immediately after the passage of the water, placed ouerthwart, which they call *Hymen*. This membrane they say is perforated in the midst to giue way to their cour-
les, and is broken or torne in their first accompanying with men, and therefore they call it *Clausum virginis*, *The locke of virginity*: for which their opinion they bring testimonies out of the holy scriptures. For it was a custome among the Iewes that the Brides should not accompany with their Bridegroomes but vpon a sheete, wherein the blood should bee kept, which was giuen to the Brides parents as a witnesse of their daughters true virginity. *Falopius* yeeldeth to this opinion, *Columbus* writeth that he hath seene it, *Laurentius* sayeth that he hath cut vp mayden children borne before their time, of three moneths, of 3, 4, 6. and 7. yeares old, and yet hee could neuer finde it though he searched curiously for it with a Probe; which (saith he) might haue beene felt to resist the Probe if there had beene any such thing, and therefore he thinketh that it is but a meere fable. Yet notwithstanding thus far he giueth credite to *Columbus* and *Falopius*, that hee thinketh there is sometimes such a membrane found, but if it be stretched ouerthwart in the middle or at the end of the necke of the wombe, then hee thinketh it is not Naturall, but an Organically diseased or of the in-
firmment being faulty in conformation. So oftentimes at the very end or extremity of the
lap there groweth sometimes a membrane sometimes a Caruncle or small peece of flesh, which affection or disease *Auicenna* calleth *clausum* or *the inclosure*; the Grecians call it *Quaritis* and such women *aphtas*, that is *imperforatas*. Some are so from their infancie, some by mishap, as by an ylcere, inflammation or some other tumor against nature; but hee that will reade more of this disease let him resort to *Actius*, *Paulus*, *Celsus*, *Albucasis* and *Oribasius*, who thinketh that there is at all no such matter. Wee must therefore finde out some other locke of Virginity. Some thinke the sides of the necke of the wombe do cleaue together in mayds and in the deuirgination are separated. *Almanzor* writeth that the necke of the wombe in virgins is very narrow and rugous, & those foulds or plights are wouen together with many small veines and arteries which are broken in the first coition. *Laurentius* is of opinion that those foure Caruncles described in the history of the wombe and placed not ouerthwart but longwise, doe so ioine together in virgins by the interuening of exceeding thin membranes, that in the first coition both the Caruncles are fretted and the mem-
branes torne, and that thence floweth the blood. This ioyning of the Caruncles *Senerinus*
Pineus a learned Chyrurgion belonging to the French King, hath notably described in a Booke which hee wrote of purpose concerning the markes or notes of Virginity, which wee also remembered before in our discourse. And thus much
shall suffice to haue spoken concerning the parts of Gene-
ration both in men and women, and the
Controuersies thereto
belonging.

Honi soit quemal y pense.

The end of the Controuersies of the Fourth Booke.

THE FIFT BOOKE,

Wherein the Historie of the Infant is accurately described, as also the principles of Generation, the Conception, the Conformation, the Nourishment, the Life, the Motion, and the Birth of the Infant, as neere as may be according to the Opinion of Hippocrates.

The Preface.

Inding this following discourse of the forming of the Infant in *Laurentius* immediately following his Historie of the parts of Generation, and considering that it contained many things not only profitable but pleasant also, I thought good (gentle Reader) to make thee partaker thereof. And the rather I heereto perswaded my selfe, because at the first sight I conceiued that my selfe also in this *my conception* should find pleasure. But it hapneth all otherwise with me then it is in naturall generation, where the infant is begotten in pleasure, though brought forth in paine. For this I assure thee was begotten with much paine and trauel, & if thy gentle hand help not in the birth, that also will be very irksome. I know I shalbe taxed by some for hanging too long in this argument, but I also know that al the authority blame hath, is from the Authors therof. The subiect of our present discourse is the history of the Infant, of the Principles of his generation, his Conception, Conformation, Nourishment, Life, Motion and Birth. Verilie a knotty & snarled skaine to vnreele; a thicket, wherein he that hasteth with bold rashnesse and temerity shall offend & stumble at euery step; he that is diligent shall entangle himself, and he that is guided by blinde ignorance shall light vpon pits and bogs, so that it will bee impossible for any man that enters into these Lifest fairely to acquite himselfe. The further he wadeth in this Riuer, the greater confluence of waters wil ouertake him, the deeper must he sound if he will finde the bottome.

We begin with the seed which is like the *Chaos*. Vpon which as the Spirit of God moued whilst it was without forme; first to preserue it & after to distinguish it, so it is in this masse of seed; the Formatiue spirit broodeth it first. After as a Spider in the center of her Lawny Canopy with admirable skil weaueth her Cipresse web, first hanging it by slender Tiesto the rooffe, and after knitting her enter braided yarn into a curious net: so the spirit first fastneth the seed to the womb with membranes and ligaments, after distinguisheth it into certaine spermatieall threds which we call *Stamina corporis*, the warpe of the bodie. To these when the second principle which is the Mothers blood accrueth, it fileth vp their voyde distances and so amasseeth them into a solid body, whicheuery day is nourished and encreased into all dimensions, furnished also with motion, sense and finally with a reasonable soule. Then as impatient of so close imprisonment, as vnstatisfied with so slender allowance, it instantly striues till this Little world arriues into the great.

After we haue thus perfected the History, we descend vnto the many and busie Controversies depending thereupon. These concerne the differences of the sexes, the Nature of the Seed with the manner of his excretion; the qualities of the Mothers blood, the accidents hapning vnto vs therefrom, with the causes of the monthly euacuation of the same; the manner of Concoction as well lawfull, both simple, double and manifold, as illegitimate and monstrous; the order and times of Conformation, not onely of the infant it selfe, but also of the membranes and vessels to which it is fastned; the Similitude of the children to theyr parents; the admirable effects of the Imagination; the causes of superfoeration; the manner and matter of the infants Nourishment; the admirable Vnion and communion of the vessels of the hart; how he breatheth by Transpiration, not by Respiration; the works of his Vitall and Animall spirits; his Scituation or position in the wombe; and finally, the nature, differences, times and causes of Birth, together with the consequences thereof. All these with many more falling in with our disputations we heere exhibit for their satisfaction whom they may concerne, and who are more desirous to know them, then able of themselves to attaine therero.

D. Muffet.

Three things
required to
perfect gene-
ration.

1. Distinction
of sexes.

A barbarous
conceit.

2. Copulation

3. Emission of
seede.

Two princi-
ples of gene-
ration.

THe propagation of kindes, as it is made in the Elements by Transmutation, and in Metals by Apposition, so it is in creatures by generation. But of Generation there are diuers manners. For some creatures engender without coition onely by affrication: Others quite contrary to the ordinarie course of Nature, by a reception of the instrument of the female. Some females also do engender within themselves without the helpe of the male. There are also some creatures which are engendered onely by putrifaction without either male or female: others are sometimes bred out of putrifaction, otherwhiles out of seede. But all these kinds of generation are maimed and imperfect, and therefore the creatures so procreated, are called *ἀναιμα, πολυύβρια καὶ ἐντρομα*, *ζῷα* vnbloody and insectile creatures, of which a man of worthy memory among vs, D. Muffet hath written a learned and curious discourse, which happely time may communicate vnto the world. The Generation of man and of the perfect creatures is farre more noble, as whereto three things are alwaies required; a diuersity or distinction of sexes, their mutuall embracements and copulations, and a permixtion of a certaine matter yssuing from them both which potentially containeth the *Idea* or forme of the particular parts of the body, and the fatall destiny of the same, and this the Grecians call *μετὰ τὴν περὶ τὴν φύσιν*.

The distinction of the Sexes is especially necessary, because Generation is not accomplished but by seeds which must be sowne in a fruitfull ground, that is, shedde into such a place as wherein their dull and sleepy faculties may be raised and rowzed vp, which we call Conception, and afterward that which is thus conceived, may be cherished, nourished, and so attaine the utmost perfection of his kinde. But because man was too hotte to performe this office (for his heate consumeth all in him and leaueth no remainder to serue for the nourishment of the infanc) it was necessary that a woman should be created (for wee will insist now onely in mankind) which might afford not onely a place wherein to cherish and conceive the seede, but also matter for the nourishment and augmentation of the same. Both these sexes of male and female doe not differ in the kinde as we call it or *species*, that is, in the essentiall forme and perfection; but onely in some accidents, to wit, in temper and in the structure and scituation of the parts of Generation. For the female sexe as well as the male is a perfection of mankind: some there bee that call a woman *Animal occasionatum*, or *Accessorium*, barbarous words to expresse a barbarous conceit; as if they should say, A Creature by the way, or made by mischance; yea some haue growne to that impudencie, that they haue denied a woman to haue a soule as man hath. The truth is, that as the soule of a woman is the same diuine nature with a mans, so is her body a necessary being, a *first* and not a second *intention of Nature*, her proper and absolute worke not her error or preuication. The difference is by the Ancients in few words elegantly set downe when they define a man, to be a creature begetting in another, a woman a Creature begetting in her self.

The second thing required to perfect generation, is the mutuall embracements of these two sexes which is called *Coitus* or coition, that is, going together, A principle of Nature whereof nothing but sinne makes vs ashamed. Neither are these embracements sufficient, vnlesse from either sexe there proceed a third thing, by which and out of which a new man may bee generated. The effusion therefore of seeds (which are indeede the immediate principles of generation) is altogether necessary, otherwise it were not a generation, but a new Creation. These three things therefore must concur to a perfect generation, a distinction of sexes, copulation, and an emission of seede from them both.

CHAP. II.

Of the Principles of generation, seede and the Mothers blood.

Hatsoeuer is generated (saith the Philosopher) is begotten out of somewhat and from somewhat; else were it as we said a new Creation no Generation; Wherefore the Ancients haue resolved that two principles must concur to generation, Seed and the Mothers blood. The seed is the principle à quo, that is, the effi-

cient or workman which formeth the Creature, and *ex quo*, that is, the matter whereof the spermaticall parts are generated. The blood hath onely the Nature of a matter and passiue principle, (we therefore vse the Schoole words because they most emphatically expresse the thing) for out of this blood the fleshy partes are generated and both the spermaticall and the fleshy are nourished. The Nature of both these principles is very obscure, which we will endeavour to make plaine on this manner. The Seed is called in Greek *σπέρμα*, *σπέρμα*, in Latine *semen*, *Genitura*, betweene which *Aristotle* puts a nice differenc, but *Hippocrates* takes them promiscuously for the same. And so we will call it Seede and Geniture, which we define: A body moyst, hot, frothy and white, consisting of the remainders of the least and perfect nourishment and the spirits mingled therewith, laboured and boyled by the vertue of the Testicles, and so made fit for the perfect generation of a living Creature. This definition doth fully and sufficiently expresse all the causes, the formall, the materiall, the efficient and the finall.

A perfect definition of seed.

The humidity, heate, frothinesse and whiteness do make the forme. The seede is moist *δυσκρετὸν & οὐκ ὄν*, that is in Power and Consistence; and therefore *Ctesias* Physician to King *Artaxerxes* was deceived, who thought that the seed of an Elephant was so dry that it would become like unto Amber; but it is necessary it should be moyst, as well that it might be moulded by the efficient, as also because it must containe the *Idea* or specificall forme of all the particules. Hot it is, that it might produce those formes, for cold entrencheth not into generation vnlesse it be by accident. It is frothy by the permixtion of the spirits and by their motion; whence it is that the Poets call *Venus* *ἀσπότης* as if shee were made of the froth or foame of the sea; and therefore seede when it is auoyded soone loseth his magnitude, because the spirits which hould it vp do vanish; whereas phlegme and other mucous matters keepe their bulke because they haue little spirits in them. It is white, because it is boyled in the Testicles and the spermaticall vessels whose inward superficies is white, as also because it containeth in it much ayre and spirits: and therefore it is but a vaine thing which *Herodotus* reporteth of the seed of *Negroes* or *Blacke-Moors*, that it is black.

The formall cause. *Ctesias* his error.

How moyst.

Why hot.

Why frothy.

The matter of the seed is double, the ouerplus of the last nourishment and spirits. That ouerplus is blood, not altered and whitened in the solid parts as the Ancients imagined, but red, pure and sincere, deriued to the Testicles and the preparing vessels from the trunk of the hollow veine through the spermaticall veines. And hence it is that those men who are very immoderate in the vse of *Venus*, auoyde sometimes bloody seede, yea now and then pure blood. Of this minde also is *Soranus* and therefore it is, sayeth he, that the Ancients called those that were of a kindred *Consanguineos*. i. of the same blood, because the seede is made of blood, which phrase we also at this day retayne. The other matter of the seede is that which maketh it fruitfull; to wit, those Spirits which wander about the body; these potentially containe the *Idea* or forme of the particular parts (for they are ayrie and moyst easily taking any impression) and passe through the spermaticall arteries to the mazey vessels of the *Parastata* and the Testicles. There they are exquisitly mingled with the blood, and oftwo is made one body, like as of that admirable complication of the spermaticall veine and arterie is made one vessell.

The materiall cause double. Blood.

Soranus. Why kinsmen are called *consanguineos*.

And spirits.

This double matter of the seede *Hippocrates* expresseth by the names of fire and water, for so he sayth sometimes, that the seede is fire, sometimes he calleth it water. It is fire by reason of the spirits which haue in them an impetuous violence or nimble agility, whence also it is called *σπέρμα δεικνύμενον* *sementurgens*, swelling seede. In respect of the blood which is the corpulency or bulke thereof, it is called *αἰματώδες* watery. Both these *Hippocrates* in his Booke *de diata* in one sentence elegantly expresseth, where he sayth, *The Soule crepeth into man being made of a mixture of fire and water*: By the Soule he meaneth the Seed, which therefore in other places he calleth *ἐν-ζυγον*, that is Animated: by Fire hee meaneth the spirits and the in-bred heat which is commonly called *innatum calidum*; by Water hee meaneth the Alimentary moysture which is blood. The fire sayeth hee moueth all things through and through, the water nourisheth all things through and through. In respect therefore of this double matter the seede carrieth the nature of both the principles of generation; of the materiall in respect of his crassament or thicke body out of which as out of their proportionable matter the spermaticall parts are generated; of the efficient and of the forme in respect of the spirits wherewith it is fulfilled. I sayed that the seed was called an efficient and formall principle, because the efficient and the forme are two actors in respect of their different operations, though in deede and trueth they are but one and the same. For the forme

Hippocrates. How seed is fire. How watry.

A hard place of *Hippocrates* explained.

How seed is both an efficient and materiall cause.

forme being diffused through the matter, maketh it to be that which it is and no other thing, & it is called *εἶδος*, the species, or *εντελεχεια* the act: but consider it as it affecteth, moueth, disposeth and worketh the matter into a proper and conuenient habitation for it selfe, and then it carrieth the nature of an efficient. The seede in respect of his body yssueth only from the vessels; but in respect of his spirits which wander vp and downe and through all, it may be sayde to yssue from all the parts of the body. This therefore is the double matter of the seede, blood and spirits.

The efficient
cause of the
seede.

The Efficients and authors of the seede are onely the Testicles, for the power called *σπέρμα*, that is, of *makeinde seede*, we attribute first of all and originally to the testicles: To the spermatieall vessels secondarily *per ἀπὸρροήν* that is, by influence and irradiation from the testicles.

The finall
cause.

The last part of the definition designeth the finall cause of the seede, to wit, the generation of a liuing creature, and the nourishment of the testicles. And thus it appeareth how this definition of seede is accomplished euery way and compleate.

Seed of two
sorts,
Of the Male.

Furthermore, seede is of two sorts whatsoever the *Peripateticks* prattle to the contrary, one of the male, another of the female; because in both sexes there are by Nature ordained Organs or instruments for the preparing, boyling and leading thereof; as also the same causes of pleasure and delight in the spending or euacuation. But yet the seede of the male is the first principle of generation and more actiue or operative; the Females the second and lesse operative, yet they are both fruitfull and powerfull for procreation, but neyther of them auailable without the helpe of the other.

The Female.

Two kinds of
seeds in both
sexes.

Hippocrates in his first Book *de Diata* maketh mention of a double kind of seed in both sexes, the one strong & hot, the other weaker and colder. The first he calleth *semen masculū* or male seede, the other *semen femininum*, or female and foemine seede: out of the diuers mixture whereof, and as they overcome one another, hee thinketh that a male or foemale creature is generated. And thus much for the first principle of Generation, which is Seede.

CHAP. III.

Of the Mothers Blood, the other principle of Generation.

What parts
are made of
this blood.

Menstruall
purgations.

A definition
of the courses.

H He other principle of our generation is the Mothers blood, to which we ascribe the Faculty of suffering onely, and not of dooing, that is to say, it is onely a principle which is wrought vpon by seed, but it selfe worketh not in the generation of man.

Of this blood are the *Parenchymata* of the bowels made, as also the flesh of the Muscles; with this as wel the spermatieall as the fleshy parts are nourished, doe encrease and attaine their seuerall perfections. This blood wee thinke is of the same nature with that which at certaine times euery moneth is purged out by the wombe, in which respect *Hippocrates* first called it *καταμήνιος αἷμα*, that is, the Menstruous or monthly blood. The Nature of this blood entangled in a thousand difficulties we will make plaine by this definition. The Menstruous blood is the excrement of the last Aliment of the fleshy parts, which at certaine times and by standing periods is in a moderate quantity purged by the wombe, but originally ordained for the Generation and Nourishment of the New creature. This definition expresseth six heads concerning the menstruall blood: the matter, the Efficient cause, the vniuersall time, the particular time, the quantity, the wayes of euacuation, and the vse which hath the nature of the finall cause.

The matter of the menstruous blood is the ouer-plus of the last Aliment. For in the nature of women there is a superfluity more then she spendeth for many reasons. First, because their heate is but weake, and cannot discusse or evaporate the reliques leste after the parts are satisfied; secondly because of the softnesse and loosenesse of their flesh; whence it is that a womans body is scarcely perspirable, that is, in respect of men they sweate but little. Thirdly, by reason of their course of life and order of diet. For they eate more moist meates, they vse bathing oftner, they sleepe more, and in a word their life is more sedentary and idle, at least they vse lesse exercise; for these reasons a woman among all creatures is followed with these monthly euacuations.

We call the matter of this blood an Excrement, not that it cannot bee assimilated or is of a hurtfull or noxious quality like an vnprofitable excrement, but because the quantity thereof redoundeth after the flesh of the parts is satiated and filled, and is returned into the veines and thence as an excrement discharged by Nature offended with an vnprofitable bur-

burthen, for there is a satierie euen of that which is good. And this is that affluence and refluxence *Hippocrates* speaketh of, that Tide of the blood sometimes flowing, again ebbing sometimes. For when the veines strut with fulnesse the hot flesh draweth the blood vnto it, which, when that attraction is satisfied and ceased, ebbeth againe into the veines. This blood therefore is laudable and Alimentary, and as *Hippocrates* writeth in his first Booke *de morbis mulierum*, floweth out red like the blood of sacrifice and soone taketh if the women be found.

Hippocrates is
pounded.

The veines being fulfilled with these remaynders of the Aliment, and burnd with the wayght of the blood whose quantity onely is offensive vnto them, they sollicit Nature to excretion. Nature, being alwayes vigilant for her own behoofe, and a true louer and cherisher of her selfe, by the expelling faculty which she hath alwayes at her command driueth out these reliques. For as a man that hath lost one or both his legges, if hee continue that fulnesse of dyer which hee vsed before, is often sollicit with a great issue of blood by the sledge, because the liuer sanguifieth as much as it was wont, which yet there wants one part or more to consume it: euen so and after no other manner is this menstruall euacuation accomplished by Nature, not being able to dispose of that plenty which by the Liuer is ministered vnto her.

The efficient
cause of the
courses.

But because Nature doth all her businesses in order and therefore prescribeth lawes vnto her selfe, she doth not indeuour this excretion in euery age, at all times, nor euery day, but at set times and by determined periods, which she of her selfe neither anticipateth nor procrastinateth; that is, doth not either preuent or foreflow vnlesse shee be prouoked and hastened before her time, or else hindered or interrupted at her owne time. These Naturall times are either vniuersall or particular. The Vniuersall time, all men do accord, beginneth for the most part in the end of the second seuen yeares, that is, at 14. yeares olde, and endeth the seauenth seuen, that is at 49. or 50. Now the reason why this blood floweth not before the 14. yeare is, because both the vessels are narrower, and beside the heate overcome with the aboundance of humour, cannot expel the reliques, which after it hath gotten more strength it is able to maister and driue as it were out of the field. Adde hereto that in the first 14. yeares a great part of the blood is consumed in the growth of the body; and beside, yea especially before the woman be fit to conceiue, Nature doth not bestow this matter of the menstruall blood vpon her.

The vniuersall
times of the
courses and
the reasons
thereof.

Now at the end of the second seauen yeares the heate begins to gather strength, to burst forth as the Sunne in his brightnes, and to rule in the Horizon of the body; from which heat doe proceede as necessary consequences, the largenes of the wayes and vessels, the motions and commotions of the humors, their subtilty or thinnesse, and finally the strength of the expelling faculty. At that time men begin to grow hayrie, to haue lustfull imaginations and to change their voyce; womens Pappes begin to swell and they to thinke vpon husbands. After the fiftieth yeare the courses cease, because the heate being now become more weake is not able to engender any notable surpluse of laudable blood, neither yet if there be any such ouerplus, is it able to euacuate or expell the same; you may adde also and especially, that Natures intention and power of procreation beeing determined; it is no more necessary that there should be any nourishment set aside for an Infant.

Why the courses
flow at 14.
yeares old.

Why they stay
at 50.

Concerning the particular times of this monthly euacuation, *Aristotle* is of opinion that it cannot be precisely set down, and almost all learned men herein consent with him. Notwithstanding it is reasonable, we say, to thinke that Nature hath set and determinate motions and established lawes, albeit wee are ignorant of them: for who was euer so neare of Natures counsel but that he might in some things erre, in somethings be to seek? These times known to her selfe she kepeth immutable and inviolate, vnlesse either the narrownes of the wayes or the thicknes of the humour doe interrupt her, or else shee bee prouoked by the acrimony of a corroding quality in the blood, or by some other outward prouocation to poure them forth before her owne stinted and limited time. Once therefore euery moneth shee endeouoreth at least, this menstruall excretion; sometimes in the full of the Moone, sometimes in the waine; and in those women we call *viragines*, that is, who are more mannish, for three dayes together, in others that are more soft, idle and delicate, (such as *Hippocrates* in his first Booke *de dieta* calleth *idolodas*, that is, waterish women) for a whole seuen-night. And againe, in the first Section of his sixt Booke *Epidem. In women that are waterish the courses continue longer.* In those women that are of a middle and meane disposition they continue foure dayes; and these we call Particular times.

The particular
times of the
courses.
Aristotle.

The

Hippocrates.

The quantity of this monthly euacuation cannot be defined. For as *Hippocrates* obserueth in his Booke *de natura muliebri*, the blood issueth more freely or more sparingly according to the variety of their colour, temperament, age, habite and the time of the yeare. Those women which are fayre and white haue such aboundance of humour, that it issueth diuerse wayes; contrary to those are browne and swart skins who are commonly drier. In moderate and meane tempered women the quantity of the courses is about two *Hemina*, that is 18. ounces which is *Hippocrates* his proportion.

The wayes of the courses.

The wayes ordayned for this euacuation are the veines of the wombe and the wombe it selfe. The veines do run from the *Hypogastricke* and spermatick branches to the bottome and necke of the wombe; by the veines of the necke of the wombe it issueth in those women which are with child, by the other in virgins and such as are not conceiued, but not *per diapedosim*, that is, by transudation, but *per anastomosim*, that is, by the opening of the orificies of large and patent veines.

Why nature purgeth the blood through the wombe.

Now if it be asked why the blood is purged through the womb; I answer, it is done by a wonderfull prouidence of Nature, that the blood being accustomed to make his iourney this way, it might after conception presently accrew for the nourishment and generation of the Infant.

The final cause of the menstruous blood double.

Hence we gather the finall cause of the menstruous blood (which was the last poynt in our definition) to be double, the generation of the *parenchymata* or substances of the bowels and the flesh, as also the nourishment and sustentation of the Infant as well whilest it is in the mothers wombe, as also after it is borne into the world. For how should the seede conceiued attaine either nourishment or increase vnlesse this blood should be disposed into those wayes wherein the Infant is conceiued? Afterward when it is borne, the same blood returneth by knowne and accustomed waies also into the pappes and there is whitened into milke to suckle it. And this we take to be the nature of the second principle of our generation, the mothers blood or the monthly courses.

CHAP. III.

Of Conception.

The order of the acceffe of the principles.

Hese two principles of Generation, Seede and the Mothers blood are not at one and the same time auoyded in coition, because the spermatick and the fleshy parts are not at one and the same time delineated. But if the generation goe rightly on, first both sexes doe affoord fruitfull and pure seedes which are poured out into the wombe as it were into a fertil field. Afterward when the filaments or threds of the solide parts are lined out, then the blood floweth thereto as well for structure of the *parenchymata* or substances of the bowels, as also for the nourishment of the whole embryo or little Infant.

Hippocrates expounded.

The man therefore and the woman ioyned together in holy wedlocke, and desirous to raise a posterity for the honour of God and propagation of their family; in their mutuall imbracements doe either of them yeeld seede, the mans leaping with greater violence. The woman at the same instant doth not onely eiaculate seede into her selfe, but also her womb snatcheth as it were and catcheth the seede of the man, and hideth it in the bottom and bottom thereof.

Conception what it is.

These seedes thus cast and drawn into the bottome of the womb are out of hand exquisitely mingled, otherwise sayeth *Hippocrates* in his Booke *de Natura pueri*, they are neither *nourished* nor *animated* together. And if any man, sayeth he in his first Booke *de diata*, do deny that the Soule is mixed with the Soule, let him be held for a dotard. Now by the Soule hee meaneth the Seed, as we haue sayed before. This mingling of the seeds is the first worke or endeavour of Nature in generation. And presently after the seeds are thus mingled, the womb, which is the most noble and almost diuine Nurse, gathereth and contracteth it selfe, and that I may vse the words of the Arabians, is so corrugated that there is no empty or void place left therein. And this it doth as being greedy to conteyne and to cherish, we say to Conceiue the feed. Moreouer, least the geniture thus layd vp should issue forth againe; the mouth or orifice of the wombe is so exquisitely shut and locked vp that it will not admit the poynt of a needle. Then the wombe rowzeth and raiseth vpp the sleepey and lurking power

power of the seeds, and that which was before but potentiall, it bringeth into act. This action of the wombe we properly call *Conception*, the Grecians *κίνησις* or *κίνησις*, and it is a Vi-
An action of the wombe.

Hippocrates in his Booke *de Principijs*, and the fift Aphorif. hath left vnto vs some signes of Conception. Some also doe gather signes of Conception out of all the parts almost of the body. We thinke a woman hath conceived, if in the confluence of their seedes there runneth a chilnesse or light horror through her whole body; or if she perceiue her wombe to contract it selfe; if she receiue the seede of man with delight, and it yssue not from her againe; if the inner mouth of the womb be exquisitely and perfectly shut; if she haue a light and wandering paine about her Nauell or *Hypogastrium*, which we call the Water course; if her monthly courses do stop vnusually; if her Paps grow hard, do swell and haue paine in them; if she be not so fit for, or desirous of *Venus* combats; if she suddenly grow mery and as suddenly againe sad beyond her accustomed manner; finally, if shee haue a loathing of her meate, and vse to cast in the morning after her bodye is a little stirred. But whether a woman be conceived with a man or a woman childe it is very hard to iudge. Notwithstanding, we may thus make coniecture out of *Hippocrates* in the 48. Aphorisme of the 5. Section. She that goeth with a manchild is well coloured, she that goeth with a woman child is swarthy or pale coloured. Againe in the same place, Male children are borne in the right side, Females in the left; and in the 38. Aphorisme of the same Section. If she haue conceived a male the right pap will swell, if a female the left: but all these signes are rather coniecturali then carry any certainty with them.

The signes of Conception.

Of a man and of a woman child.

CHAP. V.

Of the Conformation of the Parts.

HHe Generatiue faculty which before lay steeped, drowlie, and as it were intercepted in the seede, being now raised vp by heat and inbred propriety of the wombe brea-eth out into acte, as raked Cinders into a luculent flame. Then that noble and diuine builder setteth vpon her worke, and buildeth her selfe a habitation fit for the exercise and performance of all hir functions. But because shee could not performe this so great a worke without an organ or Instrument, she vseth the spirit (wherewith the froathy seede swelleth) as hir Painter or drawer to score out and delineate all the particular parts. This spirit walketh through the whole body of the seede, and diffuseth it selfe into euery part and portion thereof. This spirit is he which maketh the parts Homogenie, that is, gathereth all the particles of a kinde together, extendeth them, and as a glasse maker holloweth or boreth them by blowing into them. To this spirit *Aristotle* imputeth the Ordination, the Segregation, the Concretion, the Denfation, Rarefaction and Contraction of the matter of the parts. This *Galen* in his second Booke *de Semine*, calleth the framing Artizan, the begetter or the former of the parts of man. And *Mercurius Trismegistus* saide well, that it was the spirit which viuifieth or quickneth euery forme in the whole world, dispensing and governing all things according to the proper worth of each patticular.

The spirit is the workman.

Aristotle.

Mer. Trismegistus.

The spirit therefore is the first and immediate instrument of the soule, disporting it selfe in the bulke of the seede, and like a cunning Painter shadding out first with a rude Penfill the conformation of al parts both Similar and Organicall, the forme and Idea whereof it containeth in it selfe; afterward it addeth the lively colours, beautifying and polishing euery one in their due order.

This whole worke of conformation that admirable *Hippocrates* as *Galen* witnesseth in his first Booke *de Semine*, distinguisheth into foure times. The first time is that, wherein the seeds mingled doe yet retaine their owne forme which he calleth *γόνιμ*, for then there is nothing to be seene but the seed coagulated or sammed together, and couered as it were with a filme. The second time he calleth *κίνησις*, wherein there is a certaine rude adumbration of the parts, and as it were a fleshy masse. The third, wherein a man may see the representation of the three principall parts, the Braine, the Heart and the liuer, together with the first threads and as it were the warp of all the spermatieall parts, and this constitution of the creature he calleth *ὑπόμνησις*. The fourth and last time wherein there is a perfect separation,

The Conformation diuided into foure times.

discretion and description of all the parts, and then he calleth it *παῖς ὅς ἐστι καὶ νῆρον*, the child or the Infant. This surely is an excellent distribution, but for those that are rude such as we intend to informe, a great deale too darke and obscure. Wee will therefore endeavour our selues more manifestly to shew vnto you the whole proceſſe of Nature in the conformation of a man, and in what order all the parts are at first orderly delineated.

Natures proceſſe.

First the membranes.

Whilst the spirit, the instrument of the soule, beginneth to work vpon the masse of seed which to see to is vniforme, but indeed full of Heterogeny or different parts; First of all it seuereth the parts which are Heterogeny or vnlike one another, the thinner more noble and better furnished with spirits it hideth within; the thicker, colder and clammy (which most part are supplied by the mothers seede,) it compasseth about the former. At these cold and viscid parts of the seed it beginneth the conformation, for of them it maketh membranes, and stretcheth them out in breadth according to Natures vse and intent, shewing therein her admirable providence. For with these, as it were with defences, the more noble part of the seed is walled about and secured, and the inward spirits concluded or imprisoned which otherwise because of their tenuity would easily vanish. Adde farther, that if the membranes had not first beene made, the tender *Embryo* and the principal parts thereof would haue suffered offence from the hardnes of the wombe.

In Beasts 3.

For euen as God in the great world hath separated the fire from the earth by the interposition of water and ayre, so in the *Microcosme* or little World, the Nature of man imitating the grand Architect hath separated the Infant from the womb by the interposition of these membranes. But the nature of these membranes is not all one in Beastes and in men. For in beastes, especially such as haue hornes, we haue obserued three membranes called *Chorion*, *Amnios*, and *Allantoides*. That we call *Chorion* cleaueth wholly to the womb by the interposition of the vmbilicall veines and arteries, and in this membrane are to be scene those *Cotyledones* wouen of a fleshy and spongy substance. The second membrane called *Amnios* is thinner then the former; this compasseth round about the Creature and is thought to be the receptacle of the sweate. The third is called *Allantoides*, because it is much like that we call a Haggas pudding, for it doeth not encompasse all the Creature but only from the Breast-blade to the Hips, and may be compared to a girdle or broad swathe, and is sayed to contayne the vrine of the Creature whilest it is in the wombe. In a man there are onely two membranes to be found, the first and the second called *Chorion* and *Amnios*. The *Chorion* is nervous and strong, and encompasseth the Infant round whence haply it hath his name, either because it compasseth it as a circle or crown, or because it is *σῆμα ἑμῆς*, the conceptacle of the Infant, or because it supplyeth nourishment vnto it, for so much *χρησι* soundeth.

In men two.
Chorion.

Why in women the *Cotyledones* are not found.

This membrane like a soft bolster or pillow susteineth and supporteth al the veines and the Vmbilicall arteries; for it was not safe that the vessels of the Infant issuing out of his Nauill should go so long a journey naked without defence. In them are not (as in bruit beastes) those *Cotyledones* or knobbes like the Teates of the Breast, but only a fleshy masse made of infinite branches of veines and arteries wonderfully implicated or wouen together and filled vp with blood which supplyeth the place of those *Cotyledones*. The later writers call it the cake or Liuer of the wombe, and some *orbicularem affusionem* the round affusion. Whose vse is as another Liuer to prepare and boyle the blood for the nourishment of the Infant. Wee do rather call this round and red body (like the orbe of the Moone when it is at the full) which cleaueth onely to one part of the wombe and doth not wholly encompasse the Infant, *παχύρεας* or *καλὰ* *ἀσπῆς* the Sweete-bread of the wombe, and doe assigne vnto it that vse that the Sweete-bread hath in the lower belly, to wit, safely to support and as a pillow to beare vp the vmbilicall vessels diuersly sprinkled through the *Chorion*. But it may be demanded why an Infant hath not those *acetabula* or *Cotyledones* to tie the *Chorion* firmly to the wombe as it is in beastes? haply because a woman doth not bring forth so many yong as beastes doe; or because the wombe of a beast swelleth more outward, and therefore could not beare their burthen vnlesse it had beene fastned with stronger ties.

The vse of the cake.

Amnios.

His vse.

The other coate which immediatly encompasseth the Infant, from the softnesses and thinnes thereof is called *ἀμνίος* the Lambs-skinne: others call it the shirt, and the Arabians *Abigas*. It is loose on every side vnlesse it be at the place of the cake, where it groweth so fast to the *Chorion* that it can hardly be separated; and this coate receiveth the sweate and the vrine from whence the Infant hath no small help, for it swimmeth as it were in these waters or is couched in them as it were in a bath: beside, it maketh the birth more facile and easy because it moistneth the orifice of the wombe and maketh it more slippery.

These

These coats growing one to another seeme to make but one covering, which the Greeks cal *δευτερον καὶ ὅτι* *secunda* or *secundina*, either because it issueth last out of the womb in the birth whence we cal it commonly the *Afterbirth*, or because it is a second habitation for the Infant, the wombe being the first.

The after
birth.

The inner or more noble part of the seed being secured by these membranes or coats, more boldly vndertaketh the forming of the parts. At that time therefore the spirit walketh through the whole body of the seed, and because there are two faculties assistant to the procreating faculty, that is to say, the changing & the Forming: therefore first of all the seed is altered or changed and disposed; then almost in the same instant the first threds of the spermatall parts are together and at once skored or shaddowed out as it were in rude lines, and that is the first worke of the *Forming faculty*.

Then are to be seene three bubbles or cleare drops such as the raine rayseth when it falleth into a riuer, which are the rudiments of the three principall parts, & beside a thousand strings which are the warp, as it were, of the vessels and the spermatall parts. So that it is very likely that those oracles of *Hippo.* in his 1. book *de diata*, & in his book *de locis in homine* are most true, where he sayeth, that all the parts are inchoated or begun together, but doe not appeare neither are perfected at once but by degrees. But at what time whether the 5. or the 7. day, all these begin to be figured, he only the Creator who maketh the Infant knoweth, and none else. Yet if we will rely vpon *Hippocrates* authority or vpon our experience, which is very tickle, we may say, That the 7. day the seed hath what soever the body ought to haue, that is as I interpret it; the 7. day doe appeare the rudiments of all the spermatall parts, which also your eye may discern if you cast the masse into faire water and then diligently view it. These foundations of the spermatall parts being thus layed, every one is after accomplished in their owne order, 1. those that are most noble and most necessary, as the 3. principall parts, the Braine, the Heart and the Liuer, and the vessels to them belonging, Nerves, Arteries and Veines. The Veines are propagated from the Liuer euen to the *Chorion*, and to the same membrane are deriued arteries from the *iliacall* branches, and doe ioine with the mouths of the vessels of the wombe, so that these Vmbilicall vessels by which the Infant draweth his breath are the of-spring of more inward vessels contrary to the common opinion of the vulgar Anatomists.

The foundati-
ons of the parts
are layd at
once.
3. bladders,
Hippocrates.

The 7. day the
parts are deli-
niated.

What parts are
first formed.

The harder and more solide parts are figurated together, but not together perfected. For of the bones some are sooner perfected some later. The ribbs the lower iaw, the smal bones of the eares, the patell or collar bones, the bone *hyois*, are all bones euen from the first originall. The bones of the arme, the legge and the thigh haue their heads imperfect and meerly gristly; the bones of the vpper iaw, of the hands, of the whole spine and the rump, are nothing else at the first but gristles.

Their order.

The cause of the more speedy forming or perfecting of any part is to be referred to the vse thereof, that is, to the necessity of the finall cause; and therefore the ribbes because they make the cavity of the Chest are at first made bony, least otherwise the bowels should be compressed. The lower iaw was very necessary instantly after the birth of the Infant for his sucking & other motions. The small bones of the eares that they might rebound the better, needed be dry and hard. The patel or collar bones were necessarily made strong at the first, because they tye the arme and the shoulder blade to the trunk of the body; as also the bone *hyois* to establish the tounge. And thus may we make estimation of the other parts; in the delineation whereof the Forming quality perpetually laboureth, neuer resting till it haue made an absolute separation & description of them al. This is performed in male children the 30. day, & in females the 40. or the 42. day. So sayth *Hippocrates* in his Book *de Natura pueri*, and *de septimestri partu*. A woman child hath her cōformation at the farthest the 42. day, and a man child at the farthest at the 30.

The causes of
this order.

At what times
the conforma-
tion is accom-
plished.

This is the first conformation of the Infant made only of the body or substance of the seed, which the creature exceedeth not in magnitude. For saith *Aristotle* in his 7. Booke of his History of Creatures and the 3. chapter, If you cast the *Embryo* into cold water it will not appeare bigger then a great Pismyre; but I sayth *Laurentius*, haue often seen an Infant of 40. dayes old, as long as a mans little finger.

There is another conformation of the Infant of the other principle of Generation, that is of blood, of which the fleshy parts are framed, as the spermatall are of seed. This blood floweth through the vmbilicall veine, which is a branch of the gate veine filling the empty distances betweene the fibres, or threds of the seed.

The second
conformation
from the blood.

But whereas there are three sorts of flesh; that which groweth to the bowels they call *παρ' ὅρου*; that which adhereth to the fibres of the muscles they call absolutely flesh; and the

3. sorts of flesh.

The order of
this conforma-
tion.

third is that which is proper to every particular part. This threefold flesh we say is not generated together and at once but in order: first the *Parenchymata*, next the flesh of the particular parts, and last of all the flesh of the muscles. Of the *Parenchymata* the first that is formed, is that of the Liver, because the umbilical veine first powreth out the blood thereinto; then the *Parenchyma* of the heart, then those of the other bowels. And this is the manner and order of the conformation of the Infant, and of all the parts thereof.

CHAP. VI.

Of the Nourishment of the Infant, and how it exerciseth the Naturall Faculties.

Three kinds
of life.

IN the workes of Art men do proceed from that which is lesse perfect to that which is more perfect; right so is it in the workes of Nature. Wherefore the tender *Embryo* liueth first the most imperfect life, that is, the life of a Plant which we call the Vegetative life. Afterward growing vnto further strength, it attaineth the life of an vnreasonable creature which we call the Sensative life; and last of all the most perfect life of a man when it is endued with a reasonable soule. This *Aristotle* teacheth in his 1. Book *de generatione Animalium* where he saith, *the Infant is not made a living Creature and a man together*. But wee must vnderstand that this progresse in perfection commeth not by reason of the forme, because that is simple and cannot be diuided, but by reason of the matter, that is, of the Organes, which that noble forme and *first acte* vseth for the accomplishment of *second acts* as we call them, and all the Functions.

Aristotle.

Two kinds of
Nourishing.

The 1. life of the creature whereby it liueth from the very beginning of the Conception, is the most simple; and is maintained without that which we properly call Nourishment. And indeede what neede was there of Nourishment or restauration where there was no exhaustion or consumption of the parts? The *Embryo* at first hath sufficient to cherish it selfe out of it owne heate, and by it owne inbred spirit. But after the parts are distinguished and delineated, then presently it beginneth to be nourished and encreased, yet is not this nourishment of the same kind with that which the Infant enioyeth after it is ariued into the world. For then it sucketh Aliment by the mouth, but whilst it is in the wombe it receiueh it only by the Nauell, whatsoeuer *Democritus* and *Epicurus* say. And that did *Hippocrates* not obscurely intimate, when hee said in his Book *de Alimento*, *ἡ δὲ ἀρχαιότερον τροφή διὰ τὴν ἐπιγαστρὶν οὐραλόε*. that is, *The first Nourishment is the Nauell through the Abdomen*. After it is borne it swalloweth into the stomach meats of all kinds, before (saith *Hippocrates* in his Book *de natura pueri*) it draweth onely of the purest blood from the Mother, which is transfused into the Liver. The Infant after it is borne maketh manifold changes and alterations in the Aliment: first *Chylification*, then *Sanguification*, lastly perfect *Assimilation* which is the third concoction. Before when the Infant draweth pure blood, it giueth not thereto any new forme, but only a perfection and temper like vnto it selfe. Wherefore we ascribe to the Infant not *Chylification* nor *Sanguification*, but only the third concoction which is the particular Nourishment of the singular parts. The manner of this third & onely concoction in the Infant contained in the wombe, is thus.

One only acti-
on in the nou-
rishment of
the infant.

The true way
how the infant
is nourished.

The Infant being tyed by the mediation of vessels and membranes to the Mothers wombe, draws the purest of her blood through the mouths of those vessels inoculated one into another after a wonderfull manner. This blood thus drawne is powred into the body of the Liver through the umbilical veine, which is a branch of the gate veine, and reacheth to the Fissure of the Liver, yea you may often in dead bodies follow a probe out of it into the small veins of the Liver: Here the blood is more and more perfected, afterward the thicker and more crude part is distributed through the roots of the Gate veine into the stomacke, the spleene and the kidneyes, the excrements and reliques whereof by the spleenick and mesenterick branches are ablegated into the cauity of the guts, and there are by degrees gathered together, and in their abode are so dried that they become thick and black. The purer and better concocted part of the blood is conueyed into the trunk of the hollow vein, from which it is diffused through the whole body by the veins, as it were by small Riuer. But because the blood is not without his whey, which serueth to weft it through the small veins, therefore the whey hauing performed that his office, is partly spent in sweate by the habite of the body, partly it is drawne by the kidneyes, and so transcolated through the Vreters or vrine vessels into the bladder. For the containing of which sweat and Vrine, Nature appointed the Membrane called *Amnion*. Yet we must

The excrements
of the Infant
whereba-
stowed.

must not thinke that the Infant pisseth his vrine into his Membrane by the priuities, but it is conveyed therinto thorough the *Vrachos*, which is a long and bloodlesse Canale or pipe lengthened from the bottom of the bladder vnto the nauell. Neither hath it any Muscled belonging, because in the Infant no time is vnseasonable for the auoyding of these excrements; whereas when we auoide our vrine, we haue Muscles at the roote of the yard, to stay or to further that euacuation that it might not be performed but in conuenient time, and at our best leifure as before is said.

The vse of the *Vrachos*.

CHAP. VII.

How the Infant exerciseth his vitall Faculties.

He Infant also liueth in the womb farre otherwise then he liueth after he is borne; for neither is the chest distended & contracted, because he draweth not his breath by his mouth, neither doth he engender any vitall spirits because he draweth them from his Mother: neither lastly doth he neede the motion or worke of the Heart or the Lungs, but the heate of the particular parts is cherished, preserued and refreshed onely by Transpiration & the pulsation of the arteries, which he hath from the arteries of the mother.

The dissimilitude of the life of the Infant before and after birth.

This different life hath also a different structure, substance and vse of the vital organes, which because it hath not bene long knowne to any Anatomists of this age; albeit it was first of all discovered by *Galen* in his 61 and 15. Books of the *Use of Parts*, though obscurely; we will endeavour to make it as manifest and plaine as possibly we can.

Galen's wonderful Observations

In the *Basis* of the heart, that is, in the broad end, there appeare foure notable vessels, two in the right ventricle, the hollow veine, and the arteriall veine, and two in the left, the great Artery, and the venall Artery. The vse of these after we are borne is this. The Hollow veine which gapeth with a wide mouth into the heart, powreth the blood into the right ventricle as it were into a wide Cisterne, there it is reboyled and attenuated as well for the generation of vitall spirits as also for the nourishment of the lungs. A part therefore of it sweareth through the middle wall betwixt the ventricles into the left ventricle. Another part is carried by the Arteriall veine into the thin, rare, and spongy substance of the Lungs. The Venall Artery leadeth into the left ventricle the aer which we breath in, prepared before in the lungs where it is mingled with the blood, of which permixtion the vitall spirits are generated. This spirit the heart driueth into the trunk, and so into the branches of the great Artery. In the Infant before birth all these things are otherwise, and a farre other vse is there of all these vessels.

The vse of those vessels after birth.

For the hollow veine doth not poure this streame of blood into the right ventricle, because neither the Lungs stand in need of attenuated blood, being at that time all of them red, thicke, and immoveable, neither is there any generation of vitall spirits. The venal artery leadeth not the aer into the left ventricle, because the Infant doeth not breath by the mouth, but only hath vse of Transpiration. The great artery receiueth no vitall spirits from the heart, but by the umbilicall arteries: and therefore the arteriall veine doth not the office of a veine but of an artery, for it carrieth onely vitall spirits, but no blood. Againe, the venall artery doth the office of a veine, containing only thick and hy coloured blood for the nourishment of the Lungs. But because there was no passage from the Hollow veine to the venall artery, Nature ioyned these two vessels (which doe but touch one another) by a large and round hole through which the blood hath free passage from the Hollow veine, to the venall Artery.

The vse of the vessels before the Infant is borne.

To this hole shee hath also set a thin and cleare Membrane like a couer, which should giue way to the blood rushing out of the Hollow veine, but should prohibit it for returning again therinto. As also that by means of this membrane, the hole after birth (when there is no more vse of it) might sooner be souldered vp, hauing a principle of consolidation so neere and ready at hand. And because the arteriall veine and the great artery were distant a litle space each from other, shee hath ioyned them by a third pipe or Canale of the Nature of an Artery running a slope betweene them, that so the vitall spirit might passe freely from the great Artery into the Arteriall veine.

How the vessels of the heart are vnited.

This is that admirable vnion of the vessels of the heart in the Infant vborne, to wit, of the Hollow veine with the Venall artery, and of the great Artery with the Arteriall veine; but the shutting vp and reficcation of these vessels within a few dayes after the birth, that is indeed beyond all admiration. For that large hole whereof we spake, is so closed that there remaineth

The wonderful reficcation of the passages after birth.

no footsteps or signe of it. As for the third arteriall pipe or canale, within a few dayes it withereth and shrinketh together, & at length it groweth so small that no man would belecue there were any such thing.

Hence it may be concluded that the Infant in the womb draweth his mothers spirits by the Vmbilicall Arteries, and liueth contented onely with the pulsation of the Arteries, not at all needing the help or motion of the heart.

CHAP. VIII.

Of the motion and scituation of the Infant in the wombe, which are Animall faculties.

Why the Infant
moueth not
the first 3.
months.

His Soule being an *entelechia* or act of an Naturall organical body, doeth not nor can performe her functions without a conuenient organ or instrument. Wherefore in the first months the tender Infant by reason of the weaknes of the Braine and softnesse of the sinews is not able to moue his members. But when the bones begin to gather strength, and the nerues, membranes and ligaments, which before were full of a mucous and slimy humor begin to dry, then the Infant kicketh and moueth.

When the motion begins.
Hippocrates

The first beginning of this motion sayeth *Hippocrates* in his Booke *de Naturapueri*, and *de morbis Mulierum*, is in Male children at the 3. month, in Females at the 4. so that there is a certaine and definite proportion of the conformation and the motion of the Infant, and a double time comming between them. Male children therefore because they haue their conformation the 30. day doe moue the 90. now the 90. day maketh vp the 3. month. Females because they haue their cōformatiō the 42. day, they are moued the 120. which fulfilleth the 4. month.

The Infants
motion voluntary.

This motion of the Infant is not Naturall but voluntary, as being perfourmed by the helpe of the Muscles contracting themselves. The Muscles are contracted because the Soule so commaundeth. This commaundement is carried by a corporall spirit and conuayed thorough the Nerues, which spirit is daily generated (in the *Sinus* of the Braine or in his substance) of the Vitall which the Infant receiueth from the vmbilicall Arteries.

The scituation
of the Infant.

To this moouing faculty we must also referre the scituation or position of the Infant in the wombe. For so *Hippocrates* in his *Prognostikes* referreth the position or manner of the sick-mans lying (either prone that is downeward, or supine that is vpward, or on either side) to the weaknes and strength of the moouing faculty.

The naturall
scituation.
Hippocrates.

The Naturall scituation of the Infant is thus described by *Hippocrates* in his Booke *de Naturapueri*. *The Infant as he is placed in the wombe hath his hands at his knees, and his head bent downe to his feete.* Wherefore he sitteth in the wombe crumpled, contracted or bent round, holding his knees with his hands and bending his head betweene them, so that each eye is fixed to the thumbe of either hand, and his nose betwixt his knees.

Figura media
what it is.

This Figure though it be not exquisitely the *meane* or middle position as we call it, that is, so Naturall as that all the parts are in their due position; yet it commeth neere thereunto, and therefore is neither paynfull nor wearisome to the Infant; and for the mother very conuenient because thus the Infant taketh vp the least roome, & beside riseth not so high that it should presse or beare vp her midriffe or stomacke, as we see in some women when their burthen lyeth high they are short breasted and much more vawealdy as we vse to say.

The reason of
the position.

Moreouer this position is most fit for the easy birth of the Infant, for lying thus with his head betwixt his legs, when he seeketh meanes to get out, he is sooner turned with his head downeward to the orifice of the wombe, which manner of trauell is of all other the easiest and most secure, both for the Infant and the mother, as shall better appeare in the next Chapter.

CHAP. IX.

The exclusion or birth of the Childe.

He tender and soft particles of the Infant being now all perfected and established, he becommeth euery day greater and hotter, and requireth more nourishment, and being now not contented onely with transpiration, desireth and striueth after a more free vse of the ayre.

Now

Now when as the mother is not able to supply vnto the Infant either the ayre wherby it liueth in sufficient quantity through the narrow vmbilicall arteries, or other nourishment by the vmbilical veines, whereby it might be increased and refrigerated, the Infant then as it were vnder-taking of himselfe a beginning of motion, striueth to free himselfe from the prison and dungeon wherein he was reſtrayned; kicking therefore he breaketh the membranes wherein he was inwrapped, and arming himselfe with strong violence maketh way for his enlargement with all the strength and contention that he may.

This contention and distention the wombe ill brooking, and besides being overburthened with the waight of the Infant now growne, striueth to lay downe her load, and with all her strength by that expulsive faculty wherewith she is especially furnished she rouseth vp her self, and with violence thrusteth her guest out of possession of his true inheritance.

Thus the ioynt strife and as it were consent betwixt the Infant and the wombe bringeth to light a new man, not vpon his feete, nor side-long, but as diuine Hippocrates hath foreshewed *ἐπὶ κεφαλῇ*, that is head-long, so be his out-gate bee naturall. The reason is, because the vpper parts which hang vpon the Nauell string as at the beame of the ballance, doe ouerway the neather.

Furthermore, this strife and contention of the Infant and the wombe is assisted by the voluntary endeour of the woman in trauell, which is by drawing in her breath & by that meanes bearing down the midriffe: adde hereto the skilfull hand of the headf-woman or Midwife as we call them, for she setteth the woman in a due posture or position of parts, receiueth the Infant gently which falleth from betwixt her knees, directeth it, if it offer it selfe amisse; and finally draweth away as easily as is possible the afterbirth which stayeth behind.

Here Galen in his 15. Booke *de usu partium*, breakes out into an admiration of the immortal God; for the mouth or orifice of the womb, which in the whole time that the burthen was carried, was so exquisitely closed vp, now enlargeth it selfe to that extent that the body of the Infant passeth through it.

This birth hath no certaine or limited time in man as in other creatures, but hapneth vncertainly at any time of the yere: the reason is, because other creatures haue set times of copulation, but man because the propagation of his kinde was most necessary, is not tyed to any time or season, but left to the liberty of his appetite and guidance of his discretion. Adde hereto; that other creatures in their coitions are glutted & more then satisfied: man (I know not how) hath his appetite encreased euen in the fruition of that which he affecteth. Other creatures vse alwayes one and the same manner of dyet, which may be a bridle and restraint: Man wandreth wantonly through infinite varieties of viands and delicacies whereby he is goaded and prouoked to intemperate lust. I forbear to speake of the power of those fancies, lustfull imaginations and passions whereby euery houre as by so many furies he is racked and tormented: all which we know are of great auaille to alter the body of man.

The times of the birth of man are the 7. 8. 9. 10. and 11. months. The 7. month is the first time, because before it an Infant cannot be borne alieue into the world, neither indeede is such an exclusion properly called a birth, but an abortment. The 11. month is the last time and vtmost limit, which whosoever exceedeth, is decciued in the time of her conception, and the *Cat*, we say, hath eaten her marke. The middle months are the 8. 9. and the tenth.

By a month we meane with Hippocrates that which they call *mensis solaris*, that is to say 30. dayes. Not that the birth which we call *Septimestris*, or *Nonimestris*, or *Decimestris* doe each fulfill seuen or nine or ten whole and compleate months: for we know that there is a great latitude of the seuenth and tenth months, so that the Infant that is borne in the beginning or middle or end of the seuenth month is truly called *partus septimestris*. The beginning of the 7. month Hippocrates designed in his Booke *de septimestri partu*, where he sayeth that those Infants which we call *septimestres* are brought into the world within an hundred and fourescore daies and a peece of a day. The end of the seuenth month he limiteth in his Booke *de principijs*, where he saith that the *septimestris partus* is circumscribed within thirty weekes, that is two hundred and ten dayes; for 7. times 30. amounteth to that number.

The Infants called *Octimestres*, that is, such as are borne the eight month do neuer liue, vnlesse happely in Egypt, because the heauen and the soyle are there most gentle and benigne. The birth at nine months is most legitimate and to Nature most familiar. In the tenth month trauel is not so vocouth, in the eleuenth most rare.

But why the 7. month & the 9. should bring forth liuing Infants not the 8. the Pythagorians do refer to the power and efficacy of Numbers, the Geometricians to the duplicated proportion

The causes of a womans deliuerance.

reasons,

of the conformation and the motion, & the triplicated proportion of the motion to the birth. The *Astrologians* refer it to the diuerse and different Aspects of the Planets and Stars. But these are meere toyes.

The Physitians vpon better grounds haue found out certaine and established rules of Nature; and her ordinary Circuites and Returnes, which vnlesse shee be interrupted or prouoked, shee neuer either hasteneth or forefloweth. Wherefore seeing the Infant in the seuenth month becommeth perfect, not wanting any accomplishmēt of his parts, if at that time he haue strength sufficient, hee breaketh the Membranes and worketh out his passage, liuing and suruiuing because he is perfect, especially if it be a male childe.

But in the eight month if he be borne, albeit he haue the perfection of his parts, yet he suruiuech not, because he is not able to endure two instantly succeeding afflictions (as wee call them) or contentions; for the seuenth month being now perfected he laboureth sore and striveth for his enlargement. If therefore being weakened by that strife he againe returne to labor before hee bee refreshed, it is impossible hee should hold out or suruiue so great expence of strength and spirits, but must needs sink and faile.

Why the 8.
month Infant
liuech not.

Furthermore, at the eight month the Infant doth not liue, because he commeth after the day of birth which should haue been in the seuenth month, and before the day which is to be the ninth.

The subiect of
the Contro-
uersies follow-
ing.

Whereupon we gather, that some euill accident hath berided him, which either hath hindred his birth the seuenth month, or preuented his stay till the ninth. But because these things are somewhat obscure, we referre you for further satisfaction to the Controuersies next enliuing, wherein we will labour to assoile not onely this difficulty, but also all others which may arise concerning the difference and temper of the Sexes, the Nature and Effusion of the seede, the quality and causes of Excretion of the Mothers blood, the Lawfulness and Errors of Conception, the manner and time of Conformation, the Growth and encrease of the Infant, and how it exerciseth the Naturall, Virall and Animall Functions; and finally, concerning the Nature, Differences, Times, and Causes of the Birth.

A Dilucidation or Exposition of the Controuersies concerning the Historie of the Infant.

QUEST. I.

Of the Difference of the Sexes.

The necessity
of the distin-
ction of these
sexes.

Aristotle in his Bookes of the History and Generation of Creatures, doth often inculcate that the difference of Sexes is most necessary vnto perfect Generation, which is also sufficiently proued by the Final cause the most noble of all the rest, moouing the other causes, it selfe remaining immouueable. For as in the seed of a Plant, the power of the whole tree is potentially included & contained, which notwithstanding neuer breaketh into act, vnlesse that act be stirred vp by the heate of the earth; Right so, the seeds of the Parents containing in them the Idea or forme of the singular parts of the

the body, are neuer actuated, neuer exhibite their power and efficacy, vnlesse they be sown and as it were buried in the fruitfull Field or Garden of Nature, the wombe of the woman.

It was therefore necessary that there should be a double creature, one which should beget in another, and another that should generate in it selfe: the first we call a Male, the second a Female. The Male is originally the hotter, and therefore the first principle of the work, and besides affordeth the greatest part of the Formative power or faculty. The Female is the colder, and affordeth the place wherein the seede is conceiued, and the matter whereby the Conception is nourished and sustained, which matter is made of the crude and raw remainders of her owne aliment. The place is the wombe, which by a naturall disposition looseth the bondes wherein the spirit of the seed is fettered, and withal helpeth to adde vigour and efficacy thereunto. For if the seed should be powred into any other part of the body it would not be as we vse to say, Conceiued but putrified; not preserued, but corrupted. The matter whereby the seed is nourished is the Mothers blood. The excrement or surplusage rather the last aliment of the fleshy parts.

This difference of the Sexes do not make the essentiall distinctions of the creature: the reasons are: First because (as Aristotle sayth in his second Booke *De Generatione Animalium* and the 4. Chap. and in his 4. Book *De Historia Animalium* and the 17. Chap.) in all creatures there is not this distinction or diuersity of Sexes. Secondly, because essential differences do make a distinction of kinds: now we know that the Male and Female are both of one kinde, & onely differ in certaine accidents. But what these accidental differences are is not agreed vpon as yet.

The *Peripateticks* thinke that Nature euer intendeth the Generation of a Male, and that the Female is procreated by accident out of a weaker seede which is not able to attaine the perfection of the Male. Wherefore Aristotle thinketh, that the Woman or Female is nothing else but an error or aberration of Nature, which hee calleth *παράβασις* by a Metaphor taken from Trauellers which misse of their way and yet at length attain their iournies end; yea hee proceedeth further and saith, that the Female is a *by worke* or preuarication, yea the first monster in Nature.

Galen in the 6. and 7. chapters of his 14. Booke *de usu partium*, following Aristotle something too neere, writeth, that the Formative power which is in the seede of man being but one, doth alwayes intend the generation of one, that is the Male; but if she erre from her scope and cannot generate a Male, then bringeth she forth the Female which is the first and most simple imperfection of a male, which therefore he calleth a creature lame, occasionall and accessary, as if she were not of the *mayne*, but made *by the bie*.

Now heerein he putteth the difference betwixt her and the Male, that in Males the parts of Generation are without the body, in Females they lie within because of the weakenesse of the heate, which is not able to thrust them forth. And therefore he saith, that the necke of the wombe is nothing else but the virile member turned inward, and the bottome of the wombe nothing but the *scrotum* or cod inuerted.

But this opinion of Galen and Aristotle we cannot approue. For we thinke that Nature aswel intendeth the Generation of a Female as of a Male: and therefore it is vnworthily said that she is an Error or Monster in Nature. For the perfection of all naturall things is to be esteemed and measured by the end: now it was necessary that woman would be so formed or else Nature must haue missed of her scope, because she intended a perfect generation, which without a woman cannot be accomplished.

Those things which Galen vrgeth concerning the similitude of the parts of generatio or their differing only in scite and position, many men do esteeme very absurd. Sure we are that they fauour little of the truth of Anatomy, as we haue already prooued in the book going before: wherein wee haue sheweth how little likenesse there is betwixt the necke of the wombe & the yard, the bottome of it & the cod. Neither is the structure, figure, or magnitude of the testicles one and the same, nor the distribution & insertion of the spermatick vessels alike; wherefore we must not thinke that the Female is an imperfect Male differing onely in the position of the Genitals.

Neither yet must we thinke that the Sexes do differ in essentiall forme and perfection, but in the structure and temperament of the parts of Generation.

The woman hath a wombe ordained by Nature as a Field or seed-plot to receiue, conceiue & cherish the seed; the temper of her whole body is colder then that of a man; because she was to suggest and minister matter for the Nourishment of the Infant. And this way Aristotle in the second Chapter of his first Booke *De generatione Animalium* seemeth to incline,

What the Male is.

What the Female is.

The difference of Sexes is not essentiall.

Aristot. Error.

Galen. Error.

Disproued.

No similitude betwixt their Genitals.

How the Sexes are distinguished.

where

where he sayeth that *the Male and Female doe differ as well in respect as in sence*: In respect, because the manner of their generation is diuerse, for the female generateth in her selfe, the Male not in himselfe but in the Female: In sence, because the parts appeare other, and otherwise in the Sexes. The parts of the Female are the wombe and the rest which by a generall name are called *matrices*; the parts of a man are the virile member and the Testicles. And so much shal bee sufficient to haue beene added concerning the difference of the Sexes. But because there is more difference of the Tempers in men and women, we will insist somewhat more vpon that point.

QUEST. II.

Of the Temperament of women, whether they are colder or hotter then men.

Concerning the Temperament of Men and Women there is a notable controuersie, which if I may take vpon me to censure or arbitrate, I wil briefly acquaint you with what I haue gathered concerning this matter, out of the fountaines of the Grecians, and Cisternes of the Arabians.

There are some which thinke that women are hotter then men: others on the contrary, that men exceede women in heate by many degrees: Neither of these opinions want patrons to defend them, nor reasons to sustaine and support them.

That women
are hotter then
men.
Hippocrates.

If the Edicts of *Hippocrates* our Dictator doe stand for a Law, as truely they deserue well to doe, then shall mens part goe to the wall; for in his first Booke *de morbis mulierum*, he plainly auoucheth that women are hotter then men, his words are these: *I say that the flesh of a woman is more rare then that of a man*. Now rarity with the Philosophers is the worke of heat, to wit, his secondary quality; as it is the property of cold to condense or thicken: so it is the property of heate to rarifie or make thin. Againe in the same place he sayeth that the body of a woman draweth more suddenly and more abundantly the moysture out of the belly, then the body of a man.

Now we know that sudden and abundant traction is not accomplished without the help of notable heate, and therefore it is that *Hippocrates* in this 6. Section of his 6. Booke *Epidemion* calleth *carnes attractices*, because they are very hot. Finally, let vs see what *Hippocrates* inferreth vpon this rarity of the flesh and strong attraction of moysture. *The woman hath hotter blood, and therefore is hotter then a man*; what could he say more plainly? what more determinately?

Reasons for
this opinion.

Of the same opinion was *Parmenides* as *Aristotle* reporteth in the second chap. of his second Booke *de partibus Animalium*. But let vs see how this opinion of *Hippocrates* may be established by reason.

The first

The Temper of the whole body is to be esteemed according to the Temper of the principal parts, especially of the heart and the Liuer; and this we haue from *Galen* in his Booke *de Temperamentis*, and *De Arte parua*, where he saith: *Those whose heart is hot, are also of a hot habite of body, vnesse there be some obstacle in the Liuer; and those that haue hot Liners haue also hot habits vnesse there be some repugnancy in the Heart*. But if both these bowels doe conspire in the same Temper, then of necessity must the Temper of the whole body be like vnto them; but the Heart and the Liuer of women are hotter then of men; and therefore their whole bodies are also of a hotter temper then mens.

A womans
heart hotter
then a mans.

That the heart of a woman is hotter then the heart of a man may thus be demonstrated: the Temper of the particular parts is especially known by the strength of their action; now the actions and faculties of the heart are two, vitall as say the Physicians, and *humidus* or *irascibilis*, that is, the passion of anger as say the Platonists. Both these are more operative and liuely in a woman then in a man. The vitall faculty shyneth most evidently in the pulse.

Now the pulses of women are more quicke & frequent, of men more rare and slow as *Galen* teacheth in the 9. Chapter of his Booke of pulses *ad Tyrones*, and in the 2. chapter of his 3. booke *de Causis pulsuum*. That also *Auerroes* affirmeth in the 4. colliget: and the 19. chapter. But the frequency & swiftnesse of the pulse bewrayeth the strength of the heate; for as it is the property of cold to make the parts sluggish and dull in their motion; so heate moueth them briskly, and giueth them no rest at all.

The other faculty also of the heart which we called *irascibilis* or the passion of Anger, many of

of vs know by woeful experience to bee quicker and more vigorous in woemen then in men, for they are easily heated and vpon sleight causes; but Anger with *Galen* in his Booke de *Arte parua* is a signe of a hot heart. Hence it is that females are more bold and cruell then males. For Hunters affirme, that of Tygers, Beares, and Lyons, the females are farre fiercer then the males.

Women sooner
angry then
men.

That the Liuer of a woman is hotter then the Liuer of a man may bee proued by the same demonstration. The Naturall Faculty which hath his residence in the Liuer and is diuided in to the encreasing, nourishing and procreating vertues, is stronger in a woman then in a man. For we see that wenches grow faster then boyes, become sooner ripe and yeeld seede sooner, which is the worke of the generatiue Faculty, they are also more wanton and lasciuious, as hauing the Testicles hid within their bodyes, by which they are heated. For *Galen* saith the Testicles after the heart, are as it were another heart of Naturall heate.

The Liuer of a
woman hotter
then of a man.

The procrea-
ting Faculty.

The nourishing Faculty, which is a certaine signe of the heat of the Liuer, is more perfect in a woman then in a man, for their liuer engendreth more blood; now so much blood as we haue so much heate haue we also. Neither is this blood of theirs of any hurtfull or ill quality, but onely offensive in quantity. Beside the habit of the women is more fat, plump and delicate to see to and to feele, and altogether without haire.

The Nourish-
ing Faculty.

Finally, in women all the Animall Faculties are most perfect, their senses most sharpe, their Muscles more nimble and deliuer to mooue their ioynts, their memories more happy, their inuention more subtile, their words, which expresse the conceit of the mind, more plenti- full and abundant, and therefore *Virgile* expressing the communication of the Gods, makes *Jupiter* begin and *Venus* to answer, but addeth:

The Animall
Faculty.

*Jupiter hac paucis, at non Venus aurea contra
Pauca refert.*

Aenci. 10.

Thus in few words did *Jupiter* his royal sentence end,

But *Venus* faire in many more did thus her cause commend.

If therefore all the Faculties, Vitall, Naturall and Animall, are in women more perfect then in men, who will deny but they are also hotter then men? Neither will we passe ouer in silence that which *Macrobius* hath obserued in the 7. Booke of his *Saturnalia*, What time the bodies of men were burnt, to euery ten men they put the body of a woman, to make them the sooner take fire.

*Macrobius.
Saturnal.*

These things are indeede probable, and couered ouer with a veile of truth, which notwithstanding if we weigh in the ballance of Philosophie and of Physicke, they will appeare to be as light as vanity it selfe; we will therefore maintaine the other opinion, that men are generally hotter then women. And this we will confirme by strong and substantiall reasons, as also by authority of the best and most authenticke Authors.

That men are
hotter then
women.

There are very many things which will euince this truth, but these among the rest. The Principles of Generation; the Place in which, and out of which the Infant is generated; the Conformation; the Motion; the time of Birth; the Purgation after Birth; the Structure and Habit of all the parts; the manner of Diet and course of life: And finally, the Finall cause. All which we will briefly run through.

The places
from which
the arguments
are fetched.

If we consider the Principles of Generation, Men are generated of hotter seede then woemen. This hath *Hippocrates* elegantly declared in his first Booke de *dieta*. For acknowledging a double or twofold kinde of seede in both Sexes, a Male seede and a Female, he concludeth that of the male seede, that is the hotter and more vigorous, a man is generated; out of the weaker a Woman. Moreouer, men are generated in a hotter place. *Hippocrates* in the 48. Aphorisme of the first section, saith, Male infants are borne on the right side, females on the left. Now we know the right side is hotter then the left by reason of the Liuer. For the heart is indifferent and in the very midst, especially the Basis thereof which is the hottest part.

The principles
of generation.

The place of
Conception.

Neither are Males generated onely in the right side, but also out of the right side. For so saith *Hippocrates* in his Bookes *Epidemion*; when a man begins to grow lustfull, if his right Testicle swell, he will beget a manchild, if his left a woman. And thence also it is that he calleth the right Testicle *Masculum* the male, and the left *Famineum* the Female, because the seede of the one is very hot and exquisitely boyled and made of the purest blood, that of the other colder and thinner, hauing much whey in it because of the originall of the left spermatall veine out of the emulgent. This the Countreymen know full well, and therefore when they would haue Cow-calues, they tye the right Testicle of the Bull, that the seede may onely yssue from the left; which they learned, or might haue done, from *Hippocrates* in his book

The place out
of which the
Infant is Con-
ceived.

De

De superfætatione, where he sayeth, *When you would engender a Female, tye the right Testicle of the Male; when a Male, tye the left.*

The Conformation.

If wee respect the *conformation*, or conformation of both the Sexes, the Male is sooner perfected and parturated in the wombe; for he is accomplished the thirtieth, the Female not before the 40. day, as wee haue before noted out of *Hippocrates* in his first Booke *de diata, de natura pueri & Epidemion*: but conformation is the worke of heate. So likewise the Male is moued sooner, that is the third moneth, the Female later, that is the fourth; beside the motions of the Male are more frequent and more violent, all which are manifest signes of an abundant heate. Adde hereto that the Male borne the seuenth moneth commonly suruiue, the Female seldom or neuer.

The Lochia.

That also which is auoyded after the Infant is borne into the world called *Lochia* doeth testifie the heate of a male childe: for the woman which is deliuered of a Female is longer in her purgations, of a Male shorter, because the Male being hotter spendeth more of the bloud gathered together in the wombe. This *Hippocrates* teacheth in playne tearmes in his Booke *de morbis mulierum*: *After the birth of a mayde (sayeth hee) the longest purgation lasteth 42. dayes, but after the birth of a knaue childe (so our Fathers called a Male) the purgation lasteth as the longest but 30. dayes.*

The habit and structure.

If we consider the habite & structure of the parts of both sexes, you shall finde in men more signes of heate then in women. The habit of a woman is fatter, looser and softer; but fat is not generated but by a weake heate; woemen are also smooth without hayre. The flesh of men is more solide, their vessels larger, their voyce baser: now it is heate which amplifieth and enlargeth, as cold straitneth and contracteth.

A woman sayth *Hippocrates* in the 43. Aphorisme of the seauenth Section, is not *Ambi-dextra*, that is, cannot vse both hands as well as one, because she wanteth heat to strengthen both sides alike.

The diet.

In diet also, that is, in the custome and vsage of their liues in meat and drinke and such like, men appeare to be hotter then women.

Hippocrates in his first Booke *de diata*, *Men doe liue a more laborious life, and eat more solide meates then women, that they may gather heate and become dryer, woemens foode is more moyste;* and beside, they liue an idle and sedentarie life, pricking for the most part vpon a clout.

The finall cause.

Finally, to all these we may ad the necessity of the Finall cause which is in Naturall things the chiefe of all causes: It behoued therefore that man should be hotter, because his body was made to endure labour and trauell, as also that his minde should bee stout and inuincible to vndergoe dangers, the onely hearing whereof will driue a woman as wee say out of her little wits. The woman was ordayned to receiue and conceiue the seede of the man, to beare and nourish the Infant, gouerne and moderate the house at home, to delight and refresh her husband foreswunke with labour and well-nigh exhausted and spent with care and trauell; and therefore her body is soft, smooth and delicate, made especially for pleasure, so that whosoever vseth them for other doth almost abuse them.

The Conclusion.

Wherefore we conclude, that if you respect the principles of Generation, the place, conformation, motion, birth, purgations after birth, the habit of the whole body, the structure of the parts, the manner and order of life, and the finall cause of Creation, you shall finde that in all these respects a man is hotter then a woman.

If our aduersaries will not yeelde to all these demonstratiue arguments, let them at least giue credance to the whole Family of the Grecians both Philosophers and Physitians.

Authorities to proue men hotter.

This *Hippocrates* before the birth or incarnation as we may say of Philosophy, with a diuine spirit declareth, not darkely and obscurely but in plaine tearmes, in his first Booke *de diata*, after this manner: *Generally and vniuersally men are hotter and dryer then women (for we insist vpon mankind) and women moyster and colder then men.* That Genius and interpreter of Nature *Aristotle* in his Booke of the length and shortnes of life, sayth, *that men liue longer then women because they are hotter.* In his third Booke *de partibus Animalium*, men are stronger and more conragious. In the first and eight Chapters of the first Book of his Politicks, men in all actions are more excellent then women; surely because of their heate from whence cometh the strength of the faculties. And in the 29. Probleme of the 4. Section, he enquireth why men in winter are more apt for Venus and women in summer; hee answereth, because men who are hotter and dryer are in Summer spent as it were and broken; and women in winter because they are cold and moyst and haue little store of heat, and their humors as it were frozen or curdled, not fluxible and moouing.

Aristotle.

Galen

Galen in a thousand places establisheth this truth, but especially, in the sixth chap. of his 14. Booke *de usu partium*, where hee saith that women are more imperfect then men, because they are colder. For indeed of all qualities heate is the most operative.

Hence therefore we conceiue that it is manifest to all men who list to vnderstande the truth, that men are vniuersally hotter then women, and that those that maintaine the contrary are Apostataes from the ancient and authentick Philosophy. But because wee may seeme not fully to satisfie men by our reasons and authorities, vnlesse we answer the arguments brought and vrged on the contrary part, we will a little paine our selues and the Reader to answer them in order.

To begin therefore with the authority of *Hippocrates*, because it is a kind of wickednesse not to subscribe vnto this Father of Physicke, we will interpret his words by their force or power.

Whereas therefore he saith, that a woman hath rarer kinde of flesh then a man, we answer, that he vseth the word *Rare* abusiuely or at large for that which is lax and soft, not for that which is porous. For if we so vnderstand it, the body of a man is more rare, that is, more porous and open, and therefore they sweate more freely and more easily. And that this is *Hippocrates* meaning we appeale vnto himselfe in his Booke of Glandules, where hee saith: *It is therefore manifest, that the Chest and Paps, and the whole body of a woman is lax and soft.* And a little aboue, *A mans body is full, and like a cloath, thicke and tight both to see to and to feele to, but a woman is rare, and lax, and moyst, both to see to and to feele to.* Now laxity argueth a defect of heate which is not able to boyle and dissolue the superfluous moisture; on the contrary, solidity and fastnesse of the flesh ariseth from the perfect assimilation of wel boyled and resolued Aliments, yet is it also rare, that is, porous. Wherefore seeing the flesh of men is more solid then that of the woman, it followeth necessarily that they are also hotter.

And whereas *Hippocrates* saith, that women draw more aliment then men: Hee also abuseth the word *Traction* for that which is to receiue and conteyne. For the bodye of a woman being looser and as it were spongy, receyueth and conteyneth a greater quantity of blood. And that this is *Hippocrates* meaning, I gather from the Context of the place cited. For he illustrateth his opinion by an elegant similitude. If (saith he) you lay out all night vpon the ground the like waight of wooll, and a well wouen cloath; you shall find in the morning the wooll to waigh heauier then the cloth, because it hath sucked vp more moisture: so it is reasonable that the lax and loose flesh of women doth receiue and retaine a greater quantity of blood then the solid flesh of a man.

And whereas in the same place it followeth, that the blood of a Woman is hotter then the blood of a man, and therefore a woman of a hotter temper then a man; that we thinke is crept into *Hippocrates* text, being added by some Nouice scribe. And thus that great Learned man *Ludouicus Duretus* vnderstandeth *Hippocrates* and conceyueth of this corrupted place; as also *Christophorus a Veiga* in his Commentaries vpon *Hippocrates* Prognostiques. Wherefore wee cannot admit of *Cordanus* his interpretation, who thinketh that the blood suppressed, because transpiration is hindred, attaineth an outward and Aguish heat, and so becommeth hotter then the blood of men. For then wee must needs accuse *Hippocrates* of folly, (which were a kinde of blasphemy) because he compareth a sick woman with a sound and haile man. But if you compare the blood of both sexes diseased, the heat of a man will certainly be more intense then that of a woman, because it is ioyned with ficcity. Now *ficcity* (saith *Auerrhoes*) is the file of heate: And thus we suppose that wee haue satisfied the authorities out of *Hippocrates*. Now let vs waigh the arguments with as much diligence as we may.

Womens pulses are more frequent and swift, therefore they are hotter; for the swiftnesse or frequency of the pulse commeth from heate. Wee answer, that their pulses are more quicke and frequent, not because of the abouundance of heate, but because of the straightnesse of their organes. For the Arteries beeing small and narrowe, and oppressed with a-bouundance of crude and colde humours, could not bee so extended and dilated as in men; wherefore the necessity of life maketh recompence in the quicknes and frequency of the pulse; Nature prouiding for her selfe one way, when shee cannot another. But the pulses of men are strong and great by reason of the strength of the faculty, because a great Artery may be extended into all dimensions which a small vessell cannot be.

That which is objected concerning the two faculties of the heart, the *Irascible* and the courage, we thus dissolue: In *Hippocrates* and *Galen* *ὀργή* and *θυμός*, that is, *Iracundia* and

The Conclusion.

Answer to the Authorities.

Hippocrates expounded.

An excellent Similitude.

A place of *Hippocrates* corrupted. *Duretus*, *Veiga*.

Cordanus interpretation of the corrupted place rectified.

Auerrhoes.

Answer to the former Argument.

Why Women haue quicke Pulses.

Ira, Anger and Wrath are two distinct things. Anger is a disease of a weake mind which cannot moderate it selfe but is easily inflamed, such is in women, children and weake and cowardly men; and this we tearme fretfulnesse or pettishnes: but Wrath which is *Ira per-*
manens belongs to stout hearts, and therefore *Homer* calleth *Achilles* Anger: *ἄντι*.

Homer.

Iliad. u. Μῆνιν ἄειδε θεὰ Πηληϊάδεω Ἀχιλῆος.

O Goddesse sing the fixed rage of *Peleus* wrathfull Sonne.

Galen.

And *Galen* in his second Commentarie vpon the first Booke *Epidemion* opposeth *ἔν-
 θυος* *Iracundos*, angry men, *θυμώδεις* to wrathfull men; because these latter are of a manly
 courage and contemners of base things, the former are faint hearted or white Livered as we
 vse to tearme them. And the Temper of these two sorts is very different; for those that are
 angry, pettish, fretfull or wantle, chuse you which you will call them, are cold; but those
 that are wrathfull are hot. If therefore women be Nockthrowne or easily moued off the
 hinders, that they haue from their cold Temper and from the impotencie and weaknes of
 their mind, because they are not able to lay a law vpon themselves.

*Galen inter-
 preted by
 Hippocrates.*

And whereas *Galen* in his Booke *de arte parua* maketh *ἔνθυος* to be a signe of a hot heart,
 he abuseth the word. For *Hippocrates* in the fourth Section of the sixt Booke *Epidem.* ma-
 keth it a signe of a cold habit in expresse words, where he sayeth, *Those that haue hot bellies
 haue but cold flesh, such are thinne and veynie, and ἔνθυμώδεις* that is, angry or fretfull. Women
 therefore are peuis creatures most what, but nothing stout or strong hearted, though their
 stomacks be good. *Hippocrates* in his Booke *de morbis virginum* hath this saying, *ἀθυμώτερον φύσιν
 ἢ ἄνδρῶν*, The Nature of a woman is to be of an abiect minde.

Why females
 are fierce.

And whereas they contend that among rauinous Creatures the Females are most
 fierce, we say that the loue they beare to their yong addeth spirits and courage vnto them,
 and therefore that is rather to be accounted woodnes then fortitude. There are some cre-
 atures which because of their giddy madnesse make a shew of generosity, as the Female
 Elephant: some also there are in whome the feare of a worse condition begetteth boldnes,
 such are Panthers. In a Dogge partly his trustinesse to his maister partly his enuy maketh
 him fierce. We say therefore that Females are more churlish and fierce, but not stouter or
 stronger hearted. That which is objected concerning the strength of their naturall faculties
 is of all the rest the most friuolous and vaine.

Why women
 grow faster and
 be ripe sooner
 then men.

They say that women grow faster and doe sooner generate, and therefore they are hot-
 ter; but we say, that these are demonstratiue signes of a cold temperament. For therefore
 they grow faster and ingender sooner, because their end is nearer, for that the principles of
 their life are weaker. For as a short disease which we call *Acute*, doth suddenly run through
 his foure times; the beginning, the encrease, the height, and the declination, so that one time
 ouertaketh another; so women being of a shorter life then men, because they are colder, they
 sooner grow women, and so also sooner grow old then men. And hereto subscribeth *Aristotle*
 in the sixt Chapter of his 4. Booke *de generatione Animalium* where he saith, *That all things
 that are lesse and weake, as well in the works of Art as of Nature, doe sooner attayne vnto their end.*

Why females
 are lasciuious.

That Females are more wanton and petulant then Males, wee thinke hapneth because of
 the impotencie of their minds; for the imaginations of lustfull women are like the imagi-
 nations of brute beastes which haue no repugnancie or contradiction of reason to restraîne
 them. So brutish and beastly men are more lasciuious, not because they are hotter then o-
 ther men, but because they are brutish. Beastes do couple not to ingender but to satisfie the
 sting of lust, wise men couple that they might not couple.

That womens Testicles are hidden within their bodies is also an argument of the cold-
 nes of their Temper, because they want heate to thrust them forth. Yet for all this we doe
 not say that women do generate more then men, for they want the matter and the spirit.
 Indee they haue more blood as wee sayed euen now, and that is by reason of their colde
 Temperament which cannot discusse the reliques of the Aliment; adde heereto that the
 blood of women is colder and rawer then the blood of men. Wee conclude therefore that
 vniuersally men are hotter then women, Males then Females, as well in regard of the Na-
 turall Temper, as that which is acquired by diet and the course of life.

But now I had need heere to Apologise for my selfe for speaking so much of woemens
 weaknes; but they must attribute something to the heat of disputation, most to the current
 and streame of our Authours, least of all to mee who will bee as ready in another place to
 flourish forth their commendations as I am heere to huddle ouer their naturall imperfe-
 ctions.

QUEST.

QUEST. III.

what Seede is.

HAuing thus discoursed of the difference of the Sexes the first thing necessary to Generation, it followeth that we intreat of the Seede which is the immediate matter of the same. To this common place we may well giue the same Epithete which *Homer* was wont to giue to those places which were scituated vnder montaines, which hee calleth *πολυιδαναι*, that is, hauing many springs of liuing water. For I doubt not but the Reader shall finde it full of pleasure and contentment, full of variety and of pleasant philosophicall flowers, especially if I can acquit my selfe well in gathering them, and if they loose not their verdure and saueur now transplanted into a strange soyle. That I may therefore take euery thing in order, it wil not be amisse first to informe you what the worde it selfe in the originall signifies.

Τὸν δὲ σπέρμα, *semen* and *genitura*, Seede and Geniture, among Physitians are taken for one and the same. *Hippocrates* intituled his Booke of Seed *περὶ γόνος*. And *Galen* his *περὶ σπέρματος*. And *Hippocrates* in many places of the same Booke calleth it also *σπέρμα*, as where hee sayeth *καὶ ἐν τῷ ἀνδρὶ τὸ θηλυ σπέρμα καὶ τὸ ἀρσεν, καὶ ἐν τῇ γυναικὶ ὁμοίον*. There is as in a man so in a woman male & Female Seede. And *Galen* in his Commentary vpon the 62. Aphorisme of the first Section *σπέρμα ἰνομάζομεν καὶ γόνον καὶ γόνον*, We call Seede Geniture. *Hippocrates* also for the same useth *θόρος* in his second Booke *de Morbis*. But *Galen* in his Commentarie in 1. *Prognost.* distinguisheth betweene *θόρος* and *σπέρμα*, where he saith that *θόρος* signifieth rather the excretion of Seede. *Aristotle* in the 18. Chapter of his first Booke *de Generatione Animalium*, putteth a difference betweene Geniture and Seede, as if Geniture were *ens imperfectum*, an imperfect thing, and onely one principle of Generation, but Seede perfect, compounded of both principles. For our part we wil take them promiscuously, although the name of seed be more frequent and in more ordinary vse.

The Nature of Seede no man that I know hath yet essentially defined; *Hippocrates* in his Booke *de Genitura* calleth it, *The best and strongest part of that humour which is containd in the whole body*. *Pythagoras*, The froth of the best and most laudable blood. *Plato*, The defluxion of the spinall marrow. *Alcmaeon*, A small portion of the Brayne. *Zeno Criticus* The spirit of a man which he looseth with moisture, and the slough of the Soule. *Epicurus* A fragment of the Soule and the Body: Some of the Ancients haue defined it to be, *A hot spirit in a moisture able to moue it selfe, and to generate the same out of which it issueth*. *Aristotle* sayeth it is an Excrement. *Fernelius* describeth it on this manner. *It is that out of which originally are made all things which are according to Nature, not as out of a matter, but as out of an Efficient Principle*. But it seemeth to vs that none of all these do sufficiently expresse the nature of Seede. The five first are most imperfect, and therefore we wil not contend with them.

Aristotles description defineth onely the matter, which is the remaynder of the last Aliment; but the forme and the efficient cause it toucheth not; neither indeede doeth it expresse the whole matter of Seed, because (as we shew anone) there is a double matter of Seede, blood and spirits. So that to say that Seede is an excrement of the last Aliment, is all one as if he should haue sayed Seede is Blood. *Fernelius* definition conteyneth neyther the forme nor the matter of Seed, but attributeth to it only an operative or efficient power, whereas it is also a materiall principle: wherefore we haue here exhibited another definition perfect we hope and absolute in all his members and parts, which is this:

Seede is a moist, spumous or frothy and white body, made of the permission of the surplusage of the last Aliment & of the influent or errant spirits, boyled & laboured only by the vertue of the Testicles, and that for the perfect Generation of a Creature. We already in this Book a little before examined the singular particles of this definition, which we shall not therefore need to run ouer againe; here we wil onely prosecute a little more curiously the matter of Seede.

We therefore say that there is a double matter of Seede, the Excrement of the last Aliment, and Spirits. That this first matter is an Excrement, *Aristotle* prooueth by an elegant induction, on this manner. Whatsoeuer is containd in the body eyther is a part of the body, or an Aliment, or a Colliquation, or an excrement: Seede is not a part of the body, nor an Aliment, nor a Colliquation, and therefore an Excrement. It is not a part, because whilst it remaineth in vs there is nothing made of it, neither hath the body any vse especial-

The matter of seede double.

ly of the matter of it. Adde heereto, that if it were a part, so often as it is lost the creature should become maimed.

No Aliment.
No Colliqua-
tion.

It is not an Aliment for then it should not be auoyded, much lesse is it a Colliquation. For a Colliquation is a thing beside Nature, feede is truly naturall yea the quintessence of the Nature of man. Those things that are fat are most subiect to Colliquation or melting, but we know that fat men haue least quantity of feede. Moreouer Colliquation may bee made of any moisture in any part of the body, but the feede hath his owne determinate and limited seate wherein it is contained. Colliquation is alwayes hurtfull, but the auoyding of feed is sometimes very profitable.

But an excre-
ment.

It remaineth therefore that feed must needs be an excrement. But what manner of excrement is it? In all creatures that bring forth their young alieue there is a double excrement. The one naturall and profitable, the other vnprofitable. The first is profitable either to nourish some part, or to procreate, conceiue and breed vp the young, as *Galen* teacheth in his Commentary vpon the 39. Aphorisme of the fift Section; the other cannot bee assimilated because it is of a dissimilar substance. The first is called an excrement onely by reason of the abounding quantitie thereof. The second is noxious and hurtfull euen in qualitie also.

Excrements
double.

What is a pro-
fitable excre-
ment.

The Chylus which is made in the stomacke is acceptable euen to the stomacke which is pained about the concocting thereof, but at length it is thrust down into the gut as an ouerplus or superfluity; so that which was an excrement to the stomacke becommeth to the Liuer an Aliment. The Liuer being satisfied and glutted with blood, drives that which remaineth as a surplusage into the great veines, so the excrement that is, the superfluity of the Liuer, becommeth a conuenable aliment for the particular parts. The parts both fleshy and solid when they are satisfied with blood, do leaue that which remaineth in the veines; these reliques are by little and little drawne by the Testicles and at length are conuerted into the nature of feede. And for this cause the feede is called an excrement of the last concoction, because it is generated out of the remainders of the last Aliment. That remainder is blood, not changed or whitened by the solid parts, for the feede hath his whitenesse onely from the spermatice vessels and the Testicles; but redde and pure blood deriued from the trunk of the Hollow veine into the spermatice veines. An argument heereof is, because children and decrepit old men do not yeeld feed, for that in them there is no ouerplus left; and such wantons as doe too immoderately satisfy their inordinate concupiscence do often yeeld bloody feed, because it is not altered by the spermatice vessels and the testicles.

How euery
part ministe-
reth to ano-
ther out of his
owne aboun-
dance.

How feed be-
comes white.

The second
matter of the
feed.

There is another matter of the feede fare more noble which maketh it prolificall or fruitfull, and that is Spirits brought vnto it by the spermatice arteries, which being fierie and aery substances wandering and coursing about the whole bodye, doe containe in themselues the Idea or forme of the particular parts. Neither do these spirits onely containe the forme of the sexes, but also *ἡ ἀναγκαῖα μορφή* the fatall necessity of life and death; so that from whence we haue the acte of life, from thence also we haue the necessity of dissolution.

In regard of these spirits the feede is called an efficient and a formall principle. For the spirit is the immediate and proportionable instrument of Nature, wherby the noble Architect, that is the soule, extendeth the Membranes, produceth and lengtheneth the passages, and by a kinde of puffing sufflation perforateth them.

The double
Nature of
feed.

This therefore is the double matter of feede, blood and spirits. Hence it is that among the Philosophers the feede is esteemed to haue a double Nature; one aery, spumous or frothy; another waterish and diffuent. For in that the feede is aery it is neuer congealed or frozen, and in that it is waterish, it is no sooner out of his owne vessels but it melteth, the spirits being vanished which did vnite his parts.

How feed and
water differ,
Aristotle.

Now, whereas there are some which affirme that feed is onely waterish, because the colour is like water, as also the consistence when it hath bin but a little time out of the vessels; we will against them oppose *Aristotle* who disputeth this very point in the second chapter of his second Booke *de generatione Animalium*, where he saith, that the natures of water and feede are very different, for water by heate becommeth not thicke as feede doth. All waterish things by colde are congealed, feede is made more fluid. And in the 51. Problem of the first Section he saith, that feede is like to Flegme and water, not in Nature but onely in colour. But we proceede.

This double matter is mingled in these Labyrinths in which the veine openeth into the artery, and the artery into the veine by a wonderfull inoculation, so that of two there becommeth

commeth one vessell; an Embleme of the holy mixtion of feedes in Matrimony. For as of two vessels a veine and an artery there is made one vessell, so of a double matter blood and spirits there is made one seed, and of two seeds the Males and the Females one infant, and of two parents the husband and the wife one body.

An Embleme
of Matrimony

The blood and the spirits being thus mingled do attaine in the preparing vessels a rudiment of feede, not so much by the inbred power or faculty of the vessels themselves, as by an irradiation or beaming influence they haue from the Testicles. Finally, in the *Epididymis* and the Testicles the seed is boyled by their proper and ingenit vertue whose substance is rare, spongy and friable; and from these it is deriued into the eiacularatory vessels as an ouerplus and peculiar excrement of the Testicles. From whence it is manifest that fruitfull and prolificall seede yssueth onely out of the Testicles not from the whole body, as we shal further prooue in our next exercise.

How this mixture becometh seede.

QVEST. IIII.

Whether seede fall from all the parts of the body.

He thinkes now I see a faire and large fielde before me, wherein I may expatiate and disport my selfe a little, not restraining my discourse within those narrow cancels wherein I haue formerly confined it. It was a common receyued opinion in old time, that the seede did flow from all parts of the body. This *Hippocrates* auoucheth in his book *de genitura, de morbo sacro* or of the Epilepsie, & *de aëre, aquis & locis*, for there he saith That seede yssueth from all moysture which is contained in the body. And in another place, *Seede falleth from all the parts, sound seede from sound parts, and sicke or diseased from diseased parts*. Hence it is, that lame men beget lame children, bald men bald children, and Spleniticke men children afflicted with the Spleen. This opinion is confirmed by foure reasons. First because, in the acte of Generation or Copulation the whole body is delighted and as it were stupified with an extasie of pleasure, or if you will, suffereth a pleasant Convulsion. Whence it was that coition is called *parua Epilepsia*, a light Fit of the Falling sicknesse, as we saide euen now.

The olde and receyued opinion.
Hippocrates.

Confirmed by
foure reasons.

The second reason is, because the Childe beareth the Character of the Fathers imperfections: Balde men, balde children; Lame men, lame children, and so likewise in all the Cense of Hereditary diseases.

Thirdly, because those that are immoderate in the vse of *Venus* doe waste and consume all the parts of their bodies. Finally because children do resemble their parents in all parts of their bodies. There is an elegant History of a Boy in *Chalcedon*, who bare in his right arme from his birth certaine markes which were seated before in his Fathers right arme also.

An elegant
history.

But this opinion is gainsayed and disprooued by *Aristotle* in the 17. and 18. chapters of his first Book *de generatione Animalium*, and that with weighty arguments which we list not heere transcribe. *Fernelius* also in the seauenth Booke of his *Physiologia* and the second chap. addeth other reasons, to which we referre the studious Reader. It shall suffice vs in this place to answere the former arguments.

Aristotle.
Fernelius.

The argument drawne from the vniuersall pleasure and tickling delight of the whole body is of no force; for euen in itching the whole bodie is tickled, though onely one part itcheth. Moreouer, if the pleasure were therefore conceiued because the seed floweth from the whole body, it should not be perceiued in all the body at once but by degrees, first in one part then in another as the seede fell from this or that part. For we cannot imagine that in one moment of time seed is deriued from all the parts into the Testicles, and so into the eiacularatory vessels. Wee therefore acknowledge another cause of that pleasure whereby the whole body is delighted in Coition, to wit, the high heate, froathinesse and abundant spirits of the Seed; for that Seed so qualified, as it tickleth the parts of Generation which are of exquisite sense with his suddaine motion, it draweth the whole bodye into a sympathy and consent with them. For as if a Membrane be affected any way with paine, all the Membranes of the body conceyue a sense of dolour therewith: so when a Membrane is tickled, the whole body receyueth a sense of delight and is likewise moued therewith.

The former
arguments
answered.

Why all the
body is tickled
led in coition.

That lame men beget lame children, or maymed maymed is not perpetually true, for we see oftentimes that lame men beget perfect children, and hee that wanteth a ioynt begetteth a childe with all his ioynts.

That in immoderate coition the whole body is resolu'd and consumed, happeneth because the remainders of the Aliment and the Spirits are in such men exhausted, whereof when the parts are defrauded then they must of necessity waste and consume. And therefore *Anicen* sayeth, that the great expence of Seede wasteth the bodye fortie times so much as the expence or loosse of blood, if the losse of them both bee proportionable.

Finally, that which they obtrude concerning the likenesse of Childeren to their Parents belongeth to a higher contemplation, and shall bee disputed at large by and by in a more conuenient place; yet thus much in the meane time we say for answer, that the similitude they speake of proceedeth not so much from the crasse and thicke matter of the Seede; as from the formative faculty seated in the particular parts, and communicated to the Testicles, and at length to the Seed by the influent Spirits which are neare of kinne vnto those which haue their perpetuall residence in the parts of the body.

Wee therefore doe protest against that old error as a beggerly rudiment receiued from hand to hand among the Auncients, that the Seede falleth from all the parts of the body.

Another opinion of those that deriue the seed from the braine.

Some there are who deriue the greatest part of the Seede from the Brayne and the Spinal marrow. This opinion of theirs I will illustrate by authorities, examples and reasons. The authoritie is that of *Hippocrates* in his Booke *de Genitura*, where he sayeth, that the Seede is diffused out of the Brayne into the Loynes and the marrow of the backe, from thence into the Kidneyes, from the Kidneyes it attayneth through the middle of the Testicles to the priuy parts. In his Booke *de Natura ossium*, hee wryteth that the Ingular veynes proceede from both sides of the head into the Testicles, and thither conuay the Seede, wherefore from the Brayne to the Testicles, *Hippocrates* sheweth a double way, the spinall marrow, and the veines behinde the eares.

Authorities to proue it.

Plato in his *Timaeus* defineth Seed to be *A defluxion of the spinall marrow*. *Alcmaeon*, *A small portion of the Brayne*; whence it is that the common people thinke that the braines and marrow of the bones do engender much seede.

Histories.

For the confirmation of this opinion, there are elegant Histories in *Hippocrates* Booke *de aëre, aquis et locis*. The first is of such men as were called *μακροκεφαλοι*, the other of the Scythians.

Macrocephali what they are.

There were in tymes past among the inhabitants of *Europe* certayne men called *macrocephali* who were had in great esteeme, whose heads were long, and such were accounted noble and generous spirits. And therefore the Nurses were wont to presse the tender heads of Infants and to lengthen them with swathes, till at length those that by custome and constraint had long heads, begat children with long heads naturally and by conformation without any constraint at all.

The Scythians cut the veines behind the eares.

The Scythians hauing no skill at all in our kinde of Horse-manshippe, and riding without stirrups, grew all of them almost to be troubled with the Hipgout or sciatica, which disease to cure, they caused the veines behind their eares to be opened, which being cut asunder they after proued barren, and some thought this came to passe because the cicatrice or scarre closed vp the way of the seede descending from the Brayne. To which conceit a wise Lawyer, it may be alluding, wrote that Theeues should haue their eares cutte off least they should beget young Theeues. They conclude therefore that the greatest part of the fruitfull and best concocted seede falleth from the Brayne and the spinall marrow. This also may be confirmed by some sleight reasons.

Reasons to confirme this opinion. *Hippocrates*.

In coition the Brayne is chiefly affected; next the spinall marrow and the veines; and oftentimes as *Hippocrates* obserueth in his Books *Epidemion*, and *Lib. de internis affectionibus*, vpon the immoderate vse of Venus there followeth *Tabes dorsalis* - a consumption of the marrow of the backe.

A story out of *Albertus Magnus*.

Albertus Magnus maketh mention of a petulant and lasciuious Stage-player, whose head when he was dead was opened, and there was found but a little part of his Brayne left, the rest forfooth was consumed vpon harlots. Adde hereto, that vpon immoderate vse of women followeth baldnesse; now baldnes we know commeth from the want of a hot and fatty moysture, which kinde of moysture is spent in coition. And *Aristotle* saith that no man growes bald before he haue knowne the vse of Venus. This was often cast in *Caesars* teeth when

when he triumphed ouer the *Galles*: *Citizens keepe vp your wines, for wee bring home a bald Letcher*. And these are the authorities, histories and reasons whereby some are perswaded to thinke that the seede floweth from the head vnto the testicles: concerning this matter we will be bold to speake freely.

I confesse that *Hippocrates* had a most happy and diuine wit, which, as sayeth *Macrobius*, *would neuer deceiue any man, nor could it selfe be deceiued*. Yet herein hee hath neede to be excused, and no maruell; for in his age the Art of dissection was but rude, scarcely knowne to any man, and therefore it is that many of his sayings concerning Anatomy wee cannot either vnderstand or giue consent vnto. Sure wee are that there are no manifest or conspicuous passages as yet found from the Brayne and Spinall marrow to the Testicles, vnlesse haply some small nerues which carry onely spirits but are not capable of seed: neyther yet doe we finde any branches deriued to the Testicles from the externall iugular veines, vnlesse as all the veines of the body are continued one with another: we therefore cannot conceiue how thicke and well laboured seede should passe into the Testicles from those veines which run behind the eares.

The Story of the Scythians which they obiekt, who grew barren vpon the cutting of the veines behinde their eares is of no force; for they vnderstand not aright the cause of barrenesse. Some thinke that the Cicatrice or scar which grewe vpon the wound did shutte vppe the wayes of the seede. *Auiscn* thinketh that it came to passe because the descent of the Animal spirit was intercepted; others thinke that the arteries were cut, and so the passage of the vital spirit hindered: but these are fond assertions and sauour little of any knowledge in Anatomy; for those veines and arteries which lye behinde the eares are externall vessels. There are farre larger vessels internall, which runne into the Brayne through the holes of the skull, by which as by riuierets the brayne is watered, and by which rather then by these outward which touch not the brayne at all, the seed should fall from the head. But let vs grant that the seede falleth through these outward veines; shall we thinke that a scarre will hinder the passage, or interclude the wayes of the seede and the spirits? by no meanes. For if thicke bloud floweth and returneth through these vessels notwithstanding those hindrances, why should not the seed passe also which is full fraught with spirits and will passe through insensible pores? Wee must therefore enquire further for the cause of this sterility or barrenesse, and not impute it to the interception of the wayes. I finde in *Hippocrates* three causes of this their sterility; their much riding, their sciatica payne, and the too great effusion of bloud vpon the cutting of those veines. Continuall riding weakneth the strength of the loynes, the kidneis and the spermatick parts: now the Scythians did vse to ride perpetually and without stirrups.

That much riding may be a cause of barrenesse, *Hippocrates* sheweth in the place before quoted, where hee sayeth: *Amongst the Scythians the richest and most noble were most of all others thus affected, the poorer sorte least of all; for the noble spirits because they used to ride much incurred these mischiefes, whereas the poorer sorte went on foot*. From their frequent riding proceeded also their hip-gouts, which is the second cause of sterility. For nothing so much infirmeth and weakneth the body, and to weaknes addeth the corruption of the humors, as payne.

This payne that they might mitigate they cut the veines behinde their eares, out of which issued great abundance of bloud. And hence came the third cause of their sterility, for by the loofse of much blood which is the very treasure of Nature, theyr Braynes weere ouer cooled.

Now the Brayne is a principall part, into consent wherewith the Heart and the Liuer were eftsoones drawne: and hence came it to passe that their Seede was waterish, barren and vnfruitfull. For the principall parts are all of them knitte and tyed together in so great and in so strayght bandes of conspiration, that but one of them fayling, or faltering, both the other are sodainly deaded or be-numbed and their vigour and strength quite abated.

That their Braynes were refrigerated by the immoderate effusion of blood, *Hippocrates* playnely declareth in these wordes: *When the disease beginsnes to take hold of them, they cut both the weynes which are behinde their eares. And presently after abundance of blood yssuing forth they fall asleepe for meere weakenesse*; by which it appeareth that the cause of their barrenesse was not the closing vp of the passages, but their inordinate riding, the paine of the Sciatica

Sciatica and the refrigeration of the braine by the immoderate effusion or expence of blood and so consequently of spirits.

The obiection
of the *Macro-*
cephali answered.

That which they obiect concerning the *Macrocephali*, doth indeede prooue that the Formative Faculty yssueth from the braine vnto the Testicles, but it dooth not prooue that white and perfect seede descendeth thither from aboue.

Why the brain
is most affected
in coition.

And whereas in coition the braine and the spinall marrow are especially affected, that commeth to passe, say we, because their soft substance is soonest exhausted, and doth lesse resist the traction of the Testicles. Add heereto, that the braine is the last part wherein the traction of the Testicles doth rest and determine and therefore most affected therewith.

Empedocles
opinion.

Galen in the third Chapter of his second Booke *de Semine* writeth, that *Empedocles* doth not thinke that the seed fell from the whole body, but half of it from one parent, halfe from the other: the more excellent parts from the Father, and the more ignoble from the Mother. But it were time ill spent to insist vpon the answering of such idle conceits.

The opinion
of others.

Some haue beene of opinion, that white seede falleth from all the solid parts, passing from them into the smaller veines, out of the smaller into the greater, and in them rideth in the humors as a cloud or sediment in the vrine, and so is drawne away by the ingenite traction of the Testicles. These men *Aristotle* elegantly confuteth in the places before cited, and *Galen* in his Bookes *de Semine*.

Confuted by
Aristotle.

Auicenn opinion.

Auicenn the Prince of the Arabians contendeth, that the matter of the seede falleth vnto the Testicles from the three principall parts of the body, the braine, the Heart and the Liuer, and him haue many of the new writers followed. Neither were the Poets ignorant of this kind of Philosophy, but least it should grow common or be profaned by the rude vulgar wits, they cloaked it vnder obscure and blacke veiles and shaddowes of fables, as they would do a holy thing. For they thought it a great wickednesse and not to bee expiated, if the secrets of Philosophy were bewrayed to the common people. Wherefore they feigne that when *Venus* and *Mars* were in bed together, they were deprehended or taken in the manner, as wee say, by *Mercury*, *Neptune* and *Apollo*. *Apollo* with his rayes as with a quickning Nectar illustrateth them. Now by *Apollo* they meane the heart, whose affinitie with the sunne is so great, that they call the Sunne the heart of the world, and the heart the sunne of the body. *Neptune* the God of the Sea and the ruler of all moisture resembles the Liuer which is the fountain of benefical moisture. Vnder the name of *Mercury* that witty and wily God they designed the braine. These three principles therefore respect *Mars* coupling with *Venus*, that is, haue the ruling power in procreation.

An Elegant
Mythologie.

Thus haue you heard the diuerse and different opinions of the ancients and late writers concerning this matter, it remaineth now that wee resolute vpon something our selues, which we will do on this manner.

What wee re-
solve of.

The seed is a moyst, spumous and white body, compounded of a permixtion of blood and spirits, laboured and boyled by the Testicles, and falling onely from them in the time of generation, or from the adiacent parts. Neither do we ascribe that faculty which they call *σπέρματος ποιητικὴν* the Faculty of making seede to any other part saue onely to the testicles and their vessels. But whereas there is a double matter of the seede, blood and spirits; we thinke that the blood is red and not at all altered by the solid parts, and so falleth onely from the veines. As for the spirits which are aery, thinne and swift Natures, wandering through the whole body being neere of kin vnto the ingenite spirits of the particular parts, we thinke they fall into the Testicles out of the whole body, and bring with them the Idea or forme of the parts and their formative faculty. And in this sense haply it may be saide, that the seede falleth from all the parts of the body, but in no other.

Obiection.
Answers.

But some man may say, If the seede yssue onely from the Testicles, how may it bee that two so small bodies as the Testicles are, should be able to boile so great a quantity of seeder? I answer, that heerein appeareth the wonderfull wisdom and prouidence of the God of Nature, who hath made all official parts, not onely to draw fit and conuenient Aliment for their owne vse, but so much and so great a quantity as may suffice the other intentions of Nature also. So the Liuer draweth more blood out of the Veines of the Mesentery then is sufficient for his owne nourishment; so the heart generateth abundance of spirits; not onely for his owne vse, but to sustaine the life of all the rest of the parts. The Testicles therefore being common and official members, and the first and immediate organs of generation, do draw more blood then may suffice for their owne sustentation, which ouerplus being there arriued, is by them continually concocted and boyled into seede.

The wonder-
full prouidence
of God.

QVEST. V.

Whether women doe yeelde seede.

CONCERNING the seede of women, there is a hot contention betweene the *Peripateticks* and the *Physitians*. *Galen* in his Bookes *de Semine*, and in the 14. Booke *de usu partium*, elegantly discusseth the whole question, wherefore that which he there hath at large and in many words exemplified, wee in this place will contract and draw into a briebe summe. There shall be therefore three heads of this Disputation. First of all we will propound the reasons of the *Peripateticks*. Secondly, we will giue you a view of the opinion of the *Physitians*; and lastly we will answere all Obiections that are brought against the truth.

Aristotle in his Bookes *de Generatione Animalium* contendeth, that women neither loose any seede in the acte of generation, neither yet indeede haue any seede at all, and that for these reasons.

First, because it is absurd to thinke that in women there should be a double secretion at once of blood and seede. Secondly, because women in their voice, in their haire and in the habit of their body, are most like vnto Boyes, but boyes breede no seede. Thirdlie, because women doe sometimes conceiue without pleasure yea against their wils. For *Auerrhoes* telleth a Story of a woman who being in a Bath together with some men, receyued seed that fell from them and floated in the water, and thereupon conceiued. Fourthly, because a woman is an vnperfect male, and hath no actiue power but onely a passiue in generation. Finally, because if women should loose seed they might engender without the helpe of the male, because they haue in themselves the other principle of generation, to wit, the Menstruall blood.

On the contrary, the *Physitians* bring stronger arguments to prooue that women yeelde seede. This first of all men *Hippocrates* auoucheth in his Bookes *de Genitura* and *de diata*, where he doth not only acknowledge that women haue seede, but addeth moreouer, that in either sexe there is a twofold kinde of seede, one stronger, another weaker. *Aristotle* also himselfe in his tenth booke *de Historia Animalium* is constrained to confesse that to generation there is necessarily required a concourse of the seeds of both sexes.

Galen in this businesse hath so excellently acquitted himselfe, that he hath preuented all men after him for gaining any credit by the maintenance of this truth. Notwithstanding, we will endeauour by demonstratiue arguments to make it so manifest, as for euer all mens mouths shall be stopped.

First therefore it is agreed vpon by all men, as well *Physitians* as *Philosophers*, that Nature endeouoreth nothing rashly or vaine. If therefore there bee all the Organes for generating, boyling and deriuing or leading seede to the parts of generation in Women as in men, it must needs follow that they also doe generate, boyle and leade downe seed. Now for the preparation of seed they haue foure vessels, two veines and two Arteries, for the boyling and perfecting of seed they haue testicles, for the leading it down they haue eiacularatory vessels. And this is agreed vpon by all Anatomists.

I know well that the *Peripateticks* will obiect, that in those vessels there is conteyned a kinde of waterish moysture and serous, but nothing sufficiently boyled, and that the Testicles of women haue as much vse as the paps in men. But how miserably they are deceiued, good reader be thou iudge. If those preparing vessels do containe nothing but a whae and serous moysture, crude and vndigested, why are they contorted with so many Girations and Convolutions? why so wreathed and plighted one with another? Nature nowhere in all the body hath made any web or complication of vessels but onely for a newe coction and elaboration. Add heereto, that if these vessels do onely yeelde a waterish and serous humor, why doth the spermatieall veine insinuate it selfe into the spermatieall artery, so that of two vessels they become but one, as it is in men? Is it not rather therefore, that the double matter of the seede should be exquisitely mingled, and one body made of the permutation of blood and spirits? As for the proportion betweene womens Testicles and mens breasts, we say it is not equall. For the Pappes in men serue onely for ornament, to strengthen the chest and defend the noble parts therein contained. The Testicles of women

Three heads of this Controuersie.

The arguments of the *Peripateticks* that women haue no seed.

The opinion of the *Physitians*. *Hippocrates*, *Aristotle*.

Galen.

The reasons on the *Physitians* side.

Obiection. Answered.

That there is not the same reason or proportion in the paps of men, and the Testicles of women.

An argument
from the eia-
culatory vessels.

men vnlesse they make seede, are altogether vnprofitable. The Pappes of men haue no Glandules, neyther do they generate milke. The Testicles of women are perfect Glandules, and their substance is hollow or cauernous as they are in men. Moreover, why are the eiaculatory vessels which are inserted into the sides of the wombe, which they commonly call the horns, more intorted in women then in men, but only that the shortnes of the way might be recompensed by the variety of the complications? What neede was there of so great curiosity in this admirable worke of Nature, if it had been onely for the Generation or eiaculation of a crude and waterish humour?

Another dé-
monstration.

This demonstration we take to be strong enough and indeed not to be gayn-sayed; yet giue me leaue to strengthen it yet more with another. There is nothing more certayne then that woemen in their accompanying with men doe loose somewhat from whence comes their pleasure and delight. That therefore which is auoyded is either bloud, or a thinne and ferous humour, or perfect and laboured seed. No man in his right wits will say it is bloud; for when the courses flow there is no pleasure, no delight followes thereuppon, yea most commonly dire and terrible racking paynes. That it is not a ferous or vnconcocted humour, is conceiued by the wonderfull structure of the Preparing and by the complications of the Eiaculoric vessels. Wherefore it remayneth that it must bee something well concocted and laboured in these complications which they loose. And that is Seed, which is prooued by the white colour, the thicknesse and the spirits wherewith it is houxed and turgid.

If you dissect the organs of women which haue long refrayned the vse of men, you shall finde their vesselles and Testicles full of seede. Adde hereto that those who of a long time haue intermitted the vse of the mariage bed, or otherwise are wanton women doe in their sleepe auoyde great quantity of seede. And are not women often troubled with the *gonorrhoea* or running of the reynes and that disease which wee call *priapismus*? Yea sometimes when their genitalles are full of seede they grow into woodnesse and rage of lust, and euen to bee starke mad indeede; but after that seede is auoyded they come againe vnto themselves. Continuall experience tels vs that those Females which are castrated or gelt, will neuer admitte the vse of the Male, but the goads of lust are in them vtterly extinguished.

Another opi-
nion of some
Peripateticks.

The strength and validitie of these arguments haue driven many of the *Peripateticks* to confesse that women also doe auoyde seede, but least they should depart from the opinion of their Maister *Aristotle*, they say that that seede is vnfruitfull, hauing in it no active or operative faculty or power. So that all the active power of generation they attribute to men, comparing the man to the Artificer and the woman to the wood which hee squareth and heweth and worketh into shape or forme. The man they say yeeldeth the Soule and the forme, the woman onely the matter.

Auerroes
Albertus Mag.

The principall of this sect are *Auerroes* and *Albertus Magnus*: for, say they, whereas in euery Nature there must be a Patient correspondent and answerable to the Agent, it is most likely that the passive power is giuen to women which might answere to the active power in men. And truly to receiue the seede, to conceiue it, to beare the burthen and to nourish the Infant; are all arguments of a passive faculty.

Womens
seed is opera-
tine.

With this deuice they thinke they haue eluded and escaped the darts of the Physitians, when yet alas they wallow still in the same myre. For, to auoyde white, spumous, thicke and well concocted seede is all one as to auoyde active and operative seede. For will the spirits which are brought by the spermaticeall arteries and are exquisitely mixed with the bloude in these mazy complications, play them idlie in the conformation? Or should wee not rather beleue that the spermaticeall parts are of them generated as of their proper matter? The seed therefore of women is active as that of men, but yet it is weaker, because it is lesse hot and hath in it fewer spirits.

A strong rea-
son of *Galen*.

I will giue you a taste of one or two of *Galen*s arguments which shall manifest the foecundity and fruitfulness of womens seede.

How children
become like
their parents.

That the childe is sometimes like the father sometimes like the mother no man will deny. This similitude is either from the seede or from the menstruall bloud; not onely from the menstruall bloud, because then children should alwaies be like their mothers, neuer like their fathers; neither onely from the seede of the father, for then children should alwaies bee like the father, and neuer like the mother: the similitude therefore proceedeth from a common cause issuing from them both, which common cause is seede. The *Peripateticks* will answere that sometimes the children are neither like father nor mother, but like their grandfathers or great grandfathers, who neither actively nor passively did contribute any thing

thing to their generation. But I cannot see what they can answer to that argument of hereditary diseases.

The woman that is troubled with the Gowt bringeth forth a son subiect to the gowt, if she be subiect to the Falling sicknesse she will bring forth an Epilepticall infant, or being troubled with the Stone, a childe disposed to that disease; these diseases I hope they wil not say come by reason of the fault of the blood. For who euer was so mad to say, that the mensuall blood contained in it the Idea or forme of the particular parts? The impurity of the blood wil indeede make the childe weake and sickly; but to make a fabulous and calculous impression in the Kidneyes, or a gowtry impression in the ioyntes, is only proper to the seed, which conteyneth in it the tatall necessity of life and death.

Againe, all formation and specification (for you must giue vs leaue to vse our Schoole-terms in these matters of Art) that is, all power to set the seale or figure or difference vpon any thing, proceedeth from the seede alone. For the matter as it is a bare matter cannot change the species or forme of any thing, but the species followeth rather the Dam then the Sire. For if an Ewe be couered by a Goate, she will not bring forth a Kid but a Lamb with a hard and rugged wooll; if a Tup couple with a she-Goat, she will bring forth not a Lamb but a kid with a soft wooll, as *Athenaus* auoucheth. There proceedeth therefore from the Dam a formative Faculty, now all formative facultie as wee said is from seede none at all from the blood.

But there is a place in *Galen* which seemeth to be against vs. For in the first chap. of his 14. Booke *de usu partium* he denieth to the seede of the woman the power of procreation. A woman (saith he) because she is colder then a man, hath in her *Parastata* a thin and vnconcocted humor, which conferreth nothing to the procreation of the infant, and therefore when it hath done his office it is cast forth; but another humor, that is the seede of the man, is drawn into the wombe. We must thus vnderstand *Galen*, that in women, beside their seede, there is another waterish moysture which delighteth, tickleth and washeth their genitals; and that indeede conferreth nothing to generation, for so he saith a little after. But in the time of coition that humor suddenly and together with the seede yssueth, and therefore mooueth the sense, at other times it yssueth also by little and little and sometime without any sense at all. We conclude therefore, that women do yeeld seede which hath in it some operative or active faculty.

The vse of this seede according to *Galen* in the eleuenth chapter of his fourteenth booke *de usu partium* is manifold. First for generation, for by it as by a workman concurring together with the seed of a man, the parts are figured; and of it as of their matter the membranes are generated wherewith the infant is compassed. The second vse is to be an Aliment for the hotter seede of the man. For euery hot thing is nourished by that which is moderately cold, that is, lesse hot, as saith *Hippocrates* in his Booke *De Alimento*. The third vse is to irrigate or moisten the sides of the womb, for all the parts of the womb could not be lined or moistened by the seede of the man. The last vse *Galen* addeth, which is to open the necke of the matrix.

Argenterius derideth these vses of the seede, because nothing is nourished that doth not liue, but the seede liueth not. Againe, the seede of the woman is not eiacted into the sides of the wombe, because a womans wombe hath no hornes. But he is indeede himselfe ridiculous, endeavouring to correct *Magnificat* as wee say, when hee cannot sing *Te Deum*. Neither shall you finde any man more forward to carpe at others, then those who themselves lye most open to scorne, and disgrace, as that petulant Author doth in most passages of his workes. But for your sakes who may haply learne something by it, we will do him the honesty to answer his caills.

We say therefore, that the seed is Potentially Animated, and when it is cast into the womb that Power by the heat of the wombe is brought into an act, and therefore presently it worketh the workes of the soule; for it formeth and figurateth the parts. If then it be animated it liueth, but that life is the life of a plant. Beside, when *Galen* saith that the seede of a man is nourished by the seede of a woman, we must not be so grosse as to vnderstand him as if he meant a perfect nourishment which is made by assimilation: but because the seede of the man was hotter then the seede of the woman, it is tempered and made more dilute or fluxible by the cold and thinne seede of a woman. After the same manner we say that the spirits are nourished by the aer, and so we must vnderstand *Hippocrates* where he saith, That euery hot thing is nourished by that which is moderately cold.

A third.

of *Hippocrates*.

That

That he sayth the seede is not eiaculated into the sides of the wombe because the wombe hath no hornes, sauoureth of crasse and palpable ignorance of the insertion of the eiacularory vessels into the sides of the bottome of the wombe, and so we let it passe.

Answer to the
Peripatetikes
arguments.

It remaineth now that we make answer to the arguments of the *Peripatetikes*. First therefore,

1 That double secretion or profusion of blood and seede, we do not thinke is made together and at once but at diuers times; that is, of seed in the coition and conception, of blood immediately after the first discretion or separation of the spermaticall parts.

2 There is not the same reason of young boyes and of women. For in Boyes there is no remainder of lawdable blood of which seed should bee made, because one part of the blood is consumed in their nourishment and the rest in their growth, but in women there is abundance of superfluous blood.

3 Those women who do conceiue without pleasure haue ill affected wombes.

4 *Auerrhoes* his History we take to be a right old wines tale and no credit to be giuen therero.

5 That a woman is not an imperfect male, but a perfection of mankind wee haue abundantly proued before.

6 The last argument of *Aristotle* which carrieth most shew of truth, wee may thus answer. Although a woman haue in her selfe the efficient and materiall causes of generation, yet cannot she generate in her selfe without the helpe of the man; I speake of a lawfull generation, because her seede is but weake and too cold. We see that Hennes will lay Egges without the Cocke, which we call Addle egges because they will neuer proue Chickins, neither will Cockes egges which sometimes they lay proue Chickins. Wherefore the concurrence or confluence of the seedes of both sexes is of absolute necessity in generation.

Valesius his
opinion.

Valesius answereth this Obiection thus; If a woman be of a cold constitution, her seede is too weake to endeauour of it selfe the conformation of the parts: If the woman be hotter, then is her seede fruitfull enough and of sufficient power, but then there is in such women want of the remainder of Aliment by which the seede conceiued and formed in the wombe might be nourished. Wherefore a hot woman without a man may generate, but cannot nourish and perfect that which she hath conceiued. But if these things were so as *Valesius* would haue them, then hot and mannish maydens without the embracements of men should suffer many abortments, a thing neuer heard of: But it hath bin obserued by *Hippoc.* himselfe that the geniture yssuing from a woman who hath had the company of a man, the seventh day after conception hath bin dearticulated, so that in it hath appeared the rudiments of the three principall parts and the threds of al the spermaticall parts very conspicuous: For these are the workes of seede onely and not of blood, because the blood conferreth nothing to the conformation and discretion of the parts, neither yet floweth vnto the Conception till the description of the spermaticall parts bee begun. And thus much of the seede of women wherein I haue beene somewhat more large, because the *Aduersaries* are in this point very violent and will hardly be gainsaide, whatsoever evidence of reason is brought against them. Now we proceed to the manner of the emission of seed.

Disprooued.

QUEST. VI.

Of the Excretion of the Seede, by what power or Facultie it is accomplished.

Whether the
excretion of
seed be Natural
or Animall.

Concerning the excretion or auoyding of seede, there remains two things to be handled, two doubts to be cleared. First, by what power or Faculty this excretion is made, by the Naturall or by the Animall. Secondly, why there is so great pleasure in the emission of seede. Both these doubts it shall not be hard to assoile, yet because we would giue the Reader full satisfaction, we will insist somewhat the more particularly vpon them.

That it is Natural.
Reason. I.

That the excretion of seede is altogether Natural may thus bee demonstrated. Because euery excrement is driven forth by the power of Nature, and seede is an excrement. So the menstrual blood (which is a profitable excrement of the last aliment of the fleshy parts) is purged onely by the force of Nature at certaine times and determinate courses; whereupon we call them *Courses*. So the Chylus which is the excrement of the stomack, although it be profitable, is thrust downe into the guts by the ingenite faculty of the same stomack onely. So the excretion of the excrements of the belly and of the bladder is meerely Natural. Moreover for the excretion of seed, Nature hath ordained no Muscles at all, for there appeare

appeare none in the spermatieall vessels nor in the Testicles nor in the *Prostate* Glandules.

Happly you will say there are the muscles called *Cremasteres* which compresse the Leading vessels, by which compression the seede is strayned forth; but we do not acknowledge that vse of the *Cremaster* muscles, because in the vessels of seede which are in women there are no such muscles found, who notwithstanding auoyde seede as well as men, as hath bin proued. Hereto may be added the authority of *Hippocrates*, at least of *Polybins* in his Book *de genitura*, who referreth the cause of excretion to the spumy or frothy nature of the seed, which thence being turgid and not able to containe it selfe in his place, maketh way for his owne euacuation.

Obiection.

Answer.

Hippocrates authority.

On the contrary that the excretion of seede is Animall these arguments may perswade: First, because neither whilest we wake, nor in our sleepe there is any such excretion vnlesse the force of the imagination goe before it. Secondly because in the auoyding of seede the legges and the armes are contracted and the whole body suffereth a kinde of convulsion; whereupon as wee haue already sayed, *Democritus* calleth coition a light *Epilepsie* or falling sicknes. Thirdly, because that excretion is made sometime slower sometimes sooner according to our arbitrary will and discretion. Finally, because it is alwayes ioyned with pleasure, now pleasure is an affect of the sensatiue faculty which is meerly Animall.

That it is animall Reason. I.

We are of the same opinion concerning the eiactulation of Seede that wee were of concerning the erection of the yarde, to witte, that it is a mixt action of a Naturall and an Animall: It is Animall because it hath imagination going before and pleasure alwayes accompanying it. It is Naturall, because it is made when Naure is prouoked either by an itching or tickling quality, or oppressed with a burden of abundance and that without the help of muscles.

What we conclude of. It is a mixt action.

But it must be remembred that we here speake of that profusion of seede which is Natural, not of that which is symptomaticall, which they call the *Gonorrhoea* or running of the reyns; which neither hath any imagination going before nor pleasure accompanying it, neither yet is driven out by the strength of Nature, but falleth away by reason of the waterishnes or acrimony of the seed, the weaknes of the vessels, their convulsion and the inflammation of the neighbour parts: finally, which bringeth vpon the Patient an extenuation and consumption of the whole body. Witnes that Satyre in *Thaso* whose name was *Grypalopex*, of whom *Hippocrates* maketh mention in the 7. section of the 6. book *Epidemion*, who at the age of 25. yeares poured out his seed in great abundance night and day, and in the 30. yeare was vtterly consumed and so dyed.

The causes of the running of the reines.

A History of a Satyre.

QVEST. VII.

whence commeth the pleasure in the eiactulation of Seede.

THe wonderfull prouidence of Nature hath given to all Creatures certayne goades and prouocations of lust, and an impotent desire of copulation for the preferuation of the seuerall kindes of Creatures, because the *Individuum* or particular is of it selfe and by an inbred necessity dissoluble and mortall. And indeede this sting of pleasure was very necessary, without which man (especially the one sexe) in scorne and detestation of so brutish and base a worke, the other sexe for feare of payne and trouble, would haue abhorred this worke of Nature. The Finall cause therefore of this pleasure which is conceiued in the whole action of copulation (but especially in the emission of the Seed) is onely the conseruation or preferuation of makeinde.

The finall cause of pleasure and coition.

The Efficient causes of this pleasure we acknowledge to bee many and diuerse; to omit the rest, we will make mention only of three which are the especiall and most immediate. The first is the tickling of the turgid seed: now the seed is turgid, that is, hoven or frothy by reason of the impetuous motion of the spirits; for seede without spirits (such as is auoyded in the *Gonorrhoea*) breedeth no pleasure at all; after the same manner those that abuse the vse of women by frequent copulation haue lesse pleasure then other men, because they haue fewer spirits.

3. Efficient causes.

Yet is not this cause of it selfe sufficient to procure pleasure, such especially as is conceiued, but another cause is required, which is the celerity or swiftnesse of the motion and the excretion. For as paine is neuer caused vnlesse there bee a sudden and swift alteration

2. Problems.

Whether men
or women
haue greater
pleasure.

The answer.

so when the seed issueth by little and little or weepingly, there is no pleasure at all. Finally, to these two is added the exquisite sence of the parts of generation and their narrowness. For so the parts being tickled, and the vessels which were distended returning into their naturall scituation and constitution, there is stirred vp a wonderfull delight and pleasure. But that these things may be made more euident we wil handle heere two problems. The first, why the spirits as they passe through the other parts, Veins, Arteries, Sinnews, Membranes these last especially being of exquisite sence, together with the blood and the humors, do not induce the same pleasure which they doe in the spermatieall Organs. Haply it is, because this kinde of sensation by the wonderfull prouidence of Nature is bestowed onely vpon the genitals for the conseruation of the *species* or kinde, like as she hath giuen onely to the mouth of the stomach the sence of diuision and appetite. Or we may say, that in the other vessels there is not so sudden and headstrong an effusion of humors & spirits together.

The other Probleme is, why men and woemen that are asleepe haue great pleasure in their Nocturnal pollutions, seeing that in sleepe the sensatiue faculties are all at rest: for the Philosopher calleth sleep *ἐνυπνία* *ἢ ἀπὸ τῆς ἀλβαντικῆς*, *the rest of the first sensor.* We answered first, that the imagination in sleepe is stronger then when we are awake, as appeareth in those that walke and talke in their sleepe. Againe, in sleepe the senses are not so drowned in senselesnesse, but that they are rowzed vp by a violent obiect, and therefore such awake if they be violently stirred: and for the most part such nightly pollutions doe awaken those who are troubled with them. If you pricke a sleeping man with a Needle euen before he awake he gathereth vp his body; and if you continue he will awake though hee sleepe neuer so soundly. Now the excretion of seede in a dreame is indeede a very strong obiect to the spermatieall parts. These therefore are the causes of pleasure in the excretion or auoyding of seede. But whether the pleasure of the man or of the woman be the greater, it would be a vaine and fruitlesse disquisition to enquire. Indeed the woman conceiue pleasure more wales, that is in the auoyding of her owne seede and also in the attraction of the mans: for which cause *Tyresias* the Priest who had experience of both sexes preferred the woman in this kinde: but the pleasure of the man is more intense, partly because his seede is more hot and spirituous, and partly also because it yssueth with greater violence and with a kinde of *Almaine* leape or subsultation.

And thus much concerning the first principle of generation, that is, the seed of both sexes. Now we come to the second principle, which is the Mothers blood.

QUEST. VIII.

Whether the Menstruall Blood haue any noxious or hurtfull qualitie therein.

CONCERNING the Nature of the Menstruall blood, there hath beene and yet is so hard hold and so many opinions euen among Physitians them selues, that it were a shame to make mention of all their differences, much more to insist vpon them. But because we would pretermitt nothing that were worthy of your knowledge, wee will insist vpon the chiefe heads of the Controuersie. The first of which shall bee concerning the matter of the Courses.

Of the matter
of the courses.

All mendo agree that this blood is an excrement, for like a superfluity it is every month driuen forth of the wombe; but because there are two kinds of excrements, the one Naturall and profitable, the other altogether vnprofitable and vnaturall, we must enquire of which kinde this menstruall blood is.

That it is ill
qualitied.
Hippocrates au-
thority.

Aristotle.
Galen.

Moses.

The law
the

That it is an vnprofitable excrement and of a noxious or hurtfull quality, may bee pro- ued by the authority of famous learned men, as also by strong reasons. *Hippocrates* in his first Book *De morbis mulierum*, expresseth the malignant quality thereof in these wotds, *It fretteth the earth like Vineger, and gnaweth the body of the woman where soeuer it lighteth, and vlceraeth the parts of generation.* *Aristotle* in the 19. Chapter of his fourth Booke *De Natura Animalium* writeth, that that kind of blood is diseased and vitiated. *Galen* in the eight Chap. of his Book *de Atrabile* saith, that euery month a superfluous portion of blood vnprofitable not only in quantity but also in quality is auoided. *Moses* that great Law-giuer as we reade in holy Scripture, made an Edi& that no Menstruous woman should come into the Sanctuary, *Let her touch no holy thing, nor enter into the Sanctuary whilst the dayes of her purgation are fulfilled.* By the Lawes of the *Zabris*, those women that had their courses were interdicted company and society of men, and the places where she did stand were cleansed by fire.

Hesiodus

Hesiodus forbiddeth that any man should frequent those bathes where Menstruous women haue bathed themselves. *Pliny* also in the 28. Chapter of his 7. Booke and *Columella* doe thinke that this blood is not only vicious but poysonous. For by the touch thereof the young vines do wither, the buds of hearbes are burnt vp, yea glasses are infected with a kinde of *rabes*. If a Dogge lick of it he will run made, and wanton women are wont to bewitch their Louers with this blood, whence *Ouid* calleth it *Lunare virus*, the Moone poyson; wherefore it is not onely superfluous in quantity but in the whole quality a noysom excrement. This poysonous quality thereof women haue dayly and lamentable experience of in their owne bodies, for if it be suppressed it is a wonder to see what horrible and how many *symptomes* doe arise there-from.

If (sayeth *Hippocrates* in his first Booke *de morbis mulierum*) it be stabled about the womb & secret parts of the body, it ingendereth Inflammations, Cancers, S. Anthonies fires, and *scirrhus*, that is, hard & indolent tumours. If it returne vnto the vpper parts of the body, it breedeth many diseases which follow the Nature of the part affected and the offending humour. In the Liuer it breedeth the *Cachexia*, the Jaundise, the Dropsie. In the Spleene obstructions and *Scirrhus* tumors: in the Stomacke, depraued Appetite and strange longings: in the Heart palpitations and Syncopes or sounding; in the Lungs Vlcers and Consumptions: in the Brayne the falling sicknes and mad melancholly, and many other such like.

Amongst the new writers *Fernelius* the best learned Physitian of them all, in the 7. booke of his Physiologic, proueth that this blood is not Alimentarie nor of the same Nature with that by which the Infant is nourished in the mothers wombe, but thinketh it noxious and hurtfull both in the quantity and quality.

On the contrary we thinke, and perswade our selues wee shall also conuince others, to thinke that this blood which is monthly euacuated by the womb, is all one with that blood whereof the *Parenchymata* or flesh of our bowels are amassed, and wherewith the Infant in the wombe is nourished, and that it is in his owne nature laudable and pure blood and no way offensive to the woman but onely in the quantity thereof. And this we hope we shall euict both by authority of the Ancients and by inuincible and demonstratiue arguments.

First of all *Hippocrates* fauoureth this opinion as also doth *Galen*. *Hippocrates* in his first Booke *de morbis mulierum* hath this saying, *The blood falleth from a woman like the blood of a sick Sacrifice, which soone cloddeth or caketh together because it is sound and healthfull*. And this also he repeateth in his Booke *de Natura pueri*: now the conditions of laudable blood are, to be red and quickly to cake. *Galen* in his third Booke *de causis symptomatum*, writeth that this blood is not vnnaturall, but offendeth only in quantity. And this may also be demonstrated by good and true reasons: this blood in a sound woman (for if she be sickly the whole masse of blood is corrupted) the blood I say that is auoyded euery month by the wombe, is made of the same causes by and of which the other blood is made with which the flesh is satisfied and nourished. For the matter is the same, the same heat of the Liuer, the same vessels conteyning it, why then should there bee any difference in their qualities?

Moreover, if (as the Philosopher often vrgeth) the Finall cause be the most noble, and preuayleth in the workes of Nature ouer all the rest, why should this superfluous blood redound in the colde Nature of women, vnlesse that it might become an Aliment vnto the conceived and formed Infant? why doeth shee purge it rather by the wombe then by the nose, as it is often auoided in men? vnlesse it be to accustome her selfe to this way, that after the conception it may exhibit it selfe in place for the nourishment of the Infant.

This is the finall cause of the menstruous blood acknowledged by *Hippocrates*, *Aristotle*, *Galen*, and all the whole schoole of Physitians. *Aristotle* sayeth that such is the Nature of a woman, that their blood perpetually falleth to the wombe and the priue parts, and therefore if they be haile and sound of body and haue their courses in good order, they are neuer troubled with varices or swollen veines, neuer with the *Hemorrhoids* nor with bleeding at the nose as men are.

Now if these courses doe affect the way into the wombe for no other cause but onely for the nourishment of the Infant, then no man will deny but that it is benigne and laudable blood. For *Hippocrates* in his Booke *de Natura pueri* and in the first booke *de morbis mulierum* sayeth, that the Infant is nourished with pure and sweete blood; in the first place he sayth, that the Infant draweth out of the blood that which is the sweetest; in the second, that the woman with childe is pale all ouer, because her pure blood is consumed in the nourishment and increase of the Infant.

Fernelius opi-
nion.

The contrary
opinion that is
is naturall.

Hippocrates.

Galen.
Reasons to
proue it natu-
rall.

First.

Second

Third.

Moreover, that the blood which Nature purgeth by the womb of a sound woman is pure and Alimentary, this is a manifest argument because it returning to the paps milke is generated, and therefore Nurfes haue not their courses as long as they giue sucke, now that milke is made of the purest blood, *Hippocrates* witnesseth in his Booke *de Natura pueri*.

Why Nurfes
haue not their
courses nei-
ther yet con-
ceiue.

Aristotle in the first Chapter of his fourth Booke *de Generatione Animalium*, sayth that the nature of the Milke and of the menstruous blood is one and the same, and thence it is that those that giue sucke haue not their courses, neither yet do conceiue with childe, and if they do happen to conceiue, then their milke faileth.

Add hereto that if the impurity of the courses were so great as some would haue it, then it would follow that when women are with childe and their courses faile vpon that cause, they should be worse disposed, then if they should faile vpon other causes, because the Infant drawing away the purer part of the blood, that other which is venomous or of a malignant quality would rage so much the more hauing lost the bridle (that is, the purer blood) whereby it is restrayned: moreover those *symptomes* would be more violent in the last moneths then in the first after conception; al which is contradicted by common experience.

Conclusion.

Wherefore the menstruall blood may abound in women, but hath no other fault at al, if they be sound and haile; and is of the same Colour, Nature and Temperament with the rest of the blood conteyned in the trunk of the hollow veine, and wherewith the flesh is nourished. Yet is it called an excrement but that *Naturæ* abusiuely; because the flesh being herewith filled and satisfied doth returne that which remayneth back into the veines and voyde it out; so the Stomacke beeing satisfied with the Chylus thrusteth it into the Guttes.

Auicenna questi-
on.

But *Auicenna* maketh a question whether this menstruall blood be an excrement of the second or of the third concoction; we say it is of both but in a diuerse respect. It is an excrement of the second concoction, because the whole masse of blood hath his first Generation in the Liuer the seate of the second concoction, and from the Liuer is powred as an ouerplus or redundancie into the trunk of the hollow veine. It is an excrement of the third concoction, because it is as we sayd vomited away by the flesh when it is satisfied after the third concoction.

Answered.

Answer to
the former ar-
guments.

Those arguments which before were alleadged against this truth are but vaine and light. For as we grant that all those mischiefes and inconueniences before named doe happen in a diseased woman, so we deny that there is any such in a sound, haile and well disposed womans body. And if at any time the suppression of the courses in a sound body doeth bring forth any of those fore-mentioned *symptomes*, that commeth to passe because of the stay and abode of it, or else because euill humors doe fall together with the blood vnto the wombe which is the common sinke as it were of the body, by the permixtion of which humours the blood acquireth a malignant quality.

The discom-
odities of the
courses proue
their purity.

Those incommodities of the menstruous blood before remembred, are great arguments of the purity thereof: for those things which are most pure are soonest vitiated, and being once taynted are most offensive; so the *symptomes* of suppressed seede are more grieuous then those that come from the suppression of the courses, because the seed is the purer and fuller of spirits.

Hence it is that the carkasse of a man casteth a worse stench or sauour then the carkasse of any other creature, because a mans body is of all other the most temperate. And *Hippocrates* in his Booke *de morbis* sayth, that by how much the Aliment is better and more pure, by so much is his corruption worse and more offensive. And thus much of the Nature and quality of the menstruous blood.

QUEST. IX.

Whether the menstruous blood be the cause of those Meazels and small Pocks which are wont once in a mans life to trouble almost euery man.

IT belongeth not to this place to dispute of the Nature, differences and all the causes of the small pocks, as also whether the *varioli*, *morbilli*, *exanthemata*, and *ethymata* be of one and the same Nature or no; wee will onely touch that which pertayneth to our present purpose.

The question.

It is a very obscure question which hath a great while exercised the wits of many men, *Whether the small Pocks and Meazels which are wont once in a mans life to happen vnto him, doe come*

come by reason of the impurity of the menstruall blood. I will not heere enlarge my selfe to reckon vp vnto you all the opinions of all men which haue written of this question, but only tell you what we thinke and that as shortly and perspicuously as the Nature of the cause will giue leaue. It is a sure thing, that among ten thousand men and women there can bee scarce one found who once in their life are not afflicted with this disease. *Auenzoar* writeth that it is almost a miracle if any man escape them.

All men haue
once the small
poxe.

It is therefore a common disease because it taketh hold of all men: Now it is *Hippocrates* resolution in his Booke *de Natura hominis*, that common diseases haue also common causes. When many men at the same time labour of the same disease, wee determine that the cause of that disease is common. But what cause may this be that is so common to all men? Not the ayre, for we doe not all breath the same ayre; one man liueth in an impure ayre, another in a pure; one inhabiteth in the North another in the South; wherefore it must bee some Principle which is this common cause. This Principle the Arabians first of all men acknowledged to be the Menstruall blood (as *Anicen*, *Auenzoar*, *Halyabas* and *Auerrhoes*) whereof the *Parenchymata* of the bowels are gathered and the particular particles of the Infant are nourished.

The opinion
of the Arabi-
ans that they
come of the
impurity of
the courses.

For though this blood be pure and laudable, yet by the permixtion of the humours which fall from all the parts of the body vnto the wombe as it were into the common poomp or sinke, it becommeth impure; whence it is that as well the spermaticall as the fleshy parts beeing defyled with that corruption, are of necessity once in a mannes lyfe cleansed and depurated, no otherwise then Wine in the caske worketh and cleanseth it selfe.

The truth of this opinion that it may appeare more cleare, we will see what may be objected to it, and discusse the same as carefully as wee can, that no scruple may bee lefte behinde.

The Infant is nourished with pure blood. *ἔλεγε* sayeth *Hippocrates* in his Booke *de Natura pueri*, *ἡ ποτὶ ἀμάλου τὸ γλυκύτατον*, It draweth out of the blood that which is the sweetest: and therefore there cannot any euill quality settle vpon the solide or fleshy parts. I answered out of the sixt Chapter of *Galen*s first Booke *de causis Symptomatum*: That the Infant whilest it is small in the first months, draweth the purest part of blood; but when it becommeth larger then it draweth the pure and impure together promiscuously: or wee say, that the blood that the Infant draweth out of the veynes wherewith it is nourished is of it owne Nature pure, but is defyled by the humours which are wont to be purged by the womb. For *Aristotle* sayeth in his tenth Booke *de Historia Animalium*, that the wombe is a seruite member, ordained to expell those things of which the body behooueth to be purged.

Reasons to the
contrary.
First.
Answered;

Againe they object, if the small poxe grow vpon the impurity of the menstruall blood, why is not that ebullition or boyling of the blood instantly in the first months when the Infant is tender and weake, (and there is the greatest disposition of the causes moouing thereunto) but after many yeares yea sometimes not before olde age? why doe not acute Agues or other diseases which happen in the life time cleanse the body of that corruption? or at least actuate it.

Second

We answered out of *Hippocrates*, that one age differeth from another and one Nature from another. A poyson will sometimes lurke in the body more yeares then one, which in the end will bewray it selfe and either oppresse Nature or bee overcome by it and auoided. So the virulency and poyson of the French disease & of the leprosy wil lie hid for some yeares, and the poyson of a mad dog a great while before it shew it selfe.

Answered.

Their third reason is, That some men are troubled with the smal pox oftner then once yea many times, and therefore they proceed other-whence then from the infection of the menstruall blood. But this is a childish argument; for the disease doth therefore retorne because haply the expulsiue faculty is weak and thereupon there remaine some reliques of the matter of the disease: so sayth *Hippocrates* in the 12. Aphorisme of the 2. Section, *Reliquia morborum Recidiuos faciunt morbos*. The remainders or reliques of diseases are wont to be the causes of relapses.

Third.

Answered;

Their fourth reason is, the menstruall blood is turned into the substance of the parts by nutrition; now the parts do not suffer any ebullition but the humors onely, it is therefore absurd to imagine that the pox should be generated of their heat or ebullition; to whom we answered thus. The solide parts do not indeed worke or suffer ebullition, but they doe infect the humors with that quality which they acquire from the impuritie of those peccant humors which accompany the menstruall blood, which humors boiling and being offensive to nature, are thrust out into the skin; inso much as the parts themselves are purged by that working which is in the blood.

Fourth;

Answered;

So musty vessels (saith *Auenzoar*) do infect the wine contained in them, but if the wine do worke in a musty vessell, then it becommeth sweete ever after.

Fift.

Answered.

The fift reason is, if the poxe do arise out of the impurity of the Menstruall blood, why then are not women ouer-taken with the pox when their courses are stopped? We answer, that the blood so suppressed is only in the veins, and is not sprinkled through the substance of the parts, and therefore doth not settle that malignant quality in the solid parts.

Sixt.

Answered.

Their sixth reason. Why are not brute beasts which are full of blood and haue the matter of those monthly euacuations the matter you say of the poxe, and a working heate beside? why haue not such beasts the pox also? Haply, because they vse a drier kind of nourishment and beside lead their whole life in labor and exercise, whence it is that the reliques of their impure blood are spent and euaporated. But a man in his tender infancy sucketh abundantly, and after he is wayned neuer ceaseth eating, and beside, the first seauen yeares of his age he spenderh in great idlenesse.

Seuenth.

Answered.

Finally, seeing the fault of the Mothers blood hath continued ever since the beginning of the world, so that this disease should haue been the most ancient of all others, how com-meth it to passe that neither *Hippocrates* nor *Galen*, nor any of the *Gracians* did euer make any mention thereof; insomuch that it seemeth to be a new disease known only to the *Moore*s? It is not likely therefore that it proceedeth from the impurity of the Mothers blood.

But we say that it is very likely that the disease was of old time, but because men were more continent and liued in better order then now they do, it was not so ordinary in the former times as now it is. *Hippocrates* in his Books *Epidemion* doth often make mention of red, round, and small Pustules which he calleth *Exanthemata*; & *Atius* in his 14. book saith, that children had certaine Pustules or wheelkes which brake out all ouer their bodies. I do not therefore thinke that this disease was altogether vnkowne to the *Grecians*, but haply not so accurately described, because in those dayes by reason of their good dyet, the symptoms or accidents of the disease were not so dangerous. So euen at this day we haue knowne many full of the poxe without either Ague or vomiting, or any notable disease at all; and children oftentimes haue them and know not of it till they be gone.

Fernelius his opinion con-tuted.

They which referre the cause of the poxe to the malignant disposition of the aer, are in my opinion far wide, for then we must needs acknowledge that the aer is alwaies infected, because we see Children haue them at all times and seasons and euery yeare. Neyther then would the disease haunt Children onely, but old folke also as the plague dooth; neither would it happen onely once in a mans life, but as often as the aer is so affected, as it dooth in the plague and other Epidemiall and pestilent diseases which come from the aer.

Mercurialis his opinion.

Mercurialis that learned man in an elegant Booke hee set out concerning the diseases of children resolueth many and those very obscure problemes of the nature and causes of these small pox, but endeauouring to establish a new and vheard of cause of them, hee seemeth to be mistaken.

His opinion is, that the poxe is a new disease vnkowne altogether to the *Grecians*, and that it sprang first of all from the ill disposition of the heauens and the aer, and raged almost vpon all men; who afterward being themselves tainted, conferred the succession of the disease vpon their posterities. For as a gowty Father begetteth a gowty child, and a leprous father a leprous childe, an Epilepticall father an Epilepticall childe, why also should not a father infected with this poisonous disease communicate the same disposition to his child? These things may seeme to some very probable, but if we looke more narrowly into them, they will scarce hold water, as we say.

The first Reason.

For to knit vp all in few words, Hereditary diseases are not communicated from the Father or Mother to the childe, but by seedes. These seeds containe in them potentially the Idea, Formes and Proprieties of all the partes. So the seede of an arthriticall or calculous Father hath in it the disposition of the gowt or the stone; wherefore that disposition of the pox must remaine in the solid parts of the parent. But in those who haue had the poxe and are perfectly recouered of them, there remaineth no corruption nor any such disposition as being wholly euacuated by critical excretion and eruption of the pustles; otherwise out of doubt the disease would againe returne. How therefore shall they communicate vnto their children that poysonous disposition which now they themselves haue not in their solid parts? Neither are all diseases hereditary, but those onely which are *in being* in a mans body, and therefore putrid Agues and such other diseases as happen by accident, are not communicated to the children. Now at that time when this disease first began to rage, it must

What diseases are hereditary.

must needs be granted that it was as we say in Schooles *Morbis Fiens*, that is, a disease not subsisting but breeding, hauing his hearth or seate in the corruption of the humours, and therefore it could not be communicated to the children. Add hereto, that if these things were so, it would follow, that as we are all once in our liues troubled with the pox, so we should once in our liues be troubled with the plague. For the time hath beene when the plague raged so fierce that few men escaped it. As is the poxe so is the plague a common disease contracted from the fault and impurity of the aer, why then should not our parents leaue vs also that vnwelcome inheritance as well as they do the poxe?

We conclude therefore with the *Arabians*, that the cause of the poxe is the impurity of the Mothers blood wherewith the infant is nourished; which impurity it acquireth as well by his stay in the body beyond the limited time, as also from the permixtion of the humors which fall into the womb as vnto the sinke of the body.

QUEST. X.

Of the causes of the periodicall euacuation of the Menstrua.

ALl men know that the Menstruall blood is purged through the wombe by certaine standing and limited circuites and Courses, but the causes of this returne is a very hard thing to find out. Many do wonder why seeing all other excrements are euacuated euery day, this blood which is the excrement of the last Aliment should be auoided but once in a month.

The thicke excrements of the first concoction as they are daily generated, so they are daily auoided. The Choller is euery day thrust out of the Liuer into the bladder of the gal, and thence into the *Duodenum*; the vrine is daily transcolated from the Kidneyes vnto the bladder of vrine. So likewise the excrements of the third concoction, those of the habit of the body are spent by sweating, breathing and insensible transpiration, by the haire and the foile of the skin. Those of the braine by the palate, by the nosethrills, the eares and the eyes; those of the chest by coughing; why therefore is not the Menstruall blood euery day euacuated, seeing it hath a continuall generation?

This I thinke is to be attributed onely to the singular providence of Nature, and to the Finall cause the most excellent of all the rest. For if the blood were euery day purged away by the wombe, then could women neuer conceiue with childe, neyther yet any man haue due and comfortable vse of a woman. First conception would be hindred, because the seed powred out into the cavity of the wombe, would either fall backe or be extinguished; the coates of the wombe being irrigated, moistned and as it were inebriated or made drunke by the daily affluence of the blood. So saith *Hippocrates* in the 62. Aphorisme of the first section, *Those women that haue moist wombs do not conceiue, because their geniture is extinguished.* Beside, what pleasure or contentment could any man finde in a wife so lothsomly defiled, and that perpetually? It was not therefore fit for the accomplishment of the intention of Nature, that a womans blood should issue euery day, but only at certaine and definite times and circuites, to wit, once euery month.

But why this excretion should be made euery month not oftner nor more seldome, is a great question and I assure you very full of difficulty. *Aristotle* in the 2. and 4. *de generatione Animalium*, referreth the reason of this periodicall or certaine euacuation to the motion of the Moone, and saith; that when the Moone is in the wane womens courses do especially flow, because at that time the aer is colder and moister, from whence comes the encrease and abundance of that colde and crude humour; but *Aristotle* is by some heerein reprehended, because in the full of the Moone all things are most moiste, as appeareth by Shellfishes, Oysters, and such like. The *Peripatetickes* answer, that there is a double humiditie, one viuificall or liuely, the other excrementitious. The first is encreased in the full of the Moone, because then there is more light; the second is encreased in the wane, because then the aer is colder; now Menstruall blood is generated by a weake heate.

The *Arabians* thinke there are diuers times of this purgation, according to the diuersitie of womens ages. Young women (say they) are purged in the new Moone, and elder women in the old moone, whence cometh that common verse.

Luna vetus vetulas, iuuenes noua Luna repurgat.

Young women in the New Moone purge, Old women in the wane.

Some there are, who referre the cause of this circuite and monthly euacuation to the propriety of the month, as if the month had a peculiar power to purge the courses, as the day hath to purge the ordinary excrements. And for this wee may alleage a notable testimo-

The second

sion with the
Arabians.Why it is not
purged euery
day.The true rea-
son.Why it is pur-
ged euery
month.
Aristotles opi-
nion.The *Arabians*
opinion.A strange place
in *Hippocrates*.

ny of Hippocrates in his Booke *de septimestri partu*, where he sayeth, *In the moneths the same things are done by certaine and right reason which are done in dayes: for every moneth hayle women haue their courses as if the month had a peculiar power and efficacy in their bodies.* We must needs acknowledge that the Moone hath great power ouer inferior bodies, but that the sole cause of the Criticall daies and of this menstruall euacuation should be referred to the motion of the Moone I could neuer yet perswade my selfe.

What we resolve vpon.

How Nature is prouoked.

How hindred.

That many things are dispensed by numbers and by months I doe not deny; but to attribute any operative power to discrete quantity and to number as it is number, I thinke is vnworthy of a Philosopher. It is more wisdom to referre the cause of this periodical euacuation to the determinate motions and established lawes of Nature to vs vnkowne, which yet she neuer breaketh or abrogateth, but keepes immutable and inuolable vnlesse she bee either prouoked or hindred: for when she is prouoked she antiuerteth or hastineth the excretion auoyding the blood before her owne time. So whereas the seuenth dayes are onely truely criticall, yet Nature indeuoureth vacuations sometimes in the dayes betweene, yea and accomplisheth them, because of some prouocation comming from without, that is beside her owne lawfull contention. Againe, being hindered either by the narrowness of the passages, or by thicknes of the humours, she oftentimes procrastineth and delayeth their accustomed euacuation.

Hence it is that in some women the courses flow twice in a month, in some scarce before every fortieth day. But why the blood should flow from the wombe rather once every month then twice, or why the seauenth dayes should rather be criticall then the sixth *ἡμέρα*, *πρὶν ὅτι περὶ βαρυον οὐκ εἶναι, is above the capacity of humane wit.*

Hippocrates promise.

Not kept.

All secrets of nature not to be knowne.

Hippocrates verily promiserh in the end of his Booke *de principijs*, to make manifest the necessity of Nature why she dispenseth all things in the seauenth dayes: but I thinke he was dissuaded by the difficulty of the buisinesse, and therefore no where perfourmeth that promise. Wherefore seeing he that best could durst not aduenture vpon it, we will also ingenuously confesse our ignorance and ranke these secrets among those mysteries of Nature which she reserueth onely to her selfe to teach vs not onely in this but in other things, to obserue her administrations the better and to suspect our owne weaknes. For wee see that in the most abiect and base things of the world there are some secrets of Nature whereof either we are not at all capable or not yet sufficiently instructed in them.

And thus much concerning that other principle of Generation, the mothers blood, now it followeth that we come vnto the Conception, wherein also we shall finde some difficulties worthy the discussing.

QUEST. XI.

whether it be necessary to Conception that the Seed of both Sexes should issue together, and that with pleasure, and be presently mingled.

Auerroes opinion of the euacuation.

How finely he was gulled by a light skirts.

Auerroes Disproued.

1. Reason.

2. Reason.

WE haue already proued that both the Seeds as well the fathers as the mothers are required in a perfect Generation; but whether they ought both at once to be euacuated is not yet so eident. *Auerroes* contendeth that the euacuation of the seed into the cavity of the womb is not alwayes necessary, & that a woman may Conceive without the embracements of a man. And to this purpose he telleth a Tale of a woman who conceived the seed of a man floating in the water of a bath, so strong sayeth hee was the attractive faculty of the womb in drawing of seed. But it is great wonder that a Philosopher would be so credulous to beleue the excuse of a light-skirts, who to saue her honesty deuised this excuse by looking vpon her apron strings; for sayth he a neighbour of mine told me this tale of her selfe. The woman I cannot but commend for her wit, though not for her honesty: but *Auerroes* had forgot what his maister *Aristotle* taught him in his second Booke *de Generatione Animalium*. Seed sayeth he is altogether aerie, frothy, and if it be exposed to the ayre it presently melteth, groweth waterish and becommeth vnfruitfull. In the sixth Chapter also of his first Booke *de Generatione Animalium*, he writeth that those creatures which haue long yards or virile members are therefore vnfruitfull, because in the length of the way the seed is refrigerated. If therefore it may be refrigerated in his first and naturall concepracle, much more being exposed to the ayre or lost in the water.

Those which are called *ὑποσπασιαῖοι* whose common passage of seede and vrine is turned aside, by reason that the yarde is too hard reined with the bridle, cannot generate; not because they haue not fruitfull seede, but because hanging a little in the contortion of the yard,

yard, it cannot immediately be conueyed into the wombe whilst it reteineth his heat and spirits, as saith *Galen* in the 3. chapter of his 15. Booke *de usu partium*.

Doth not *Hippocrates* in his first Booke *de Morbis mulierum* affirme that to be a cause of sterility and barrenesse in women when the womb is peruerterd or distorted, because then the seed cannot directly passe without delay vnto the inner orifice of the same? It is therefore necessary *O Auerrhoes* that there be a direct and impetuous or forcible eiaculation of the seed of the man into the wombe of the woman. Furthermore, because in brute beasts which couerone the other, the eiaculation of the seed into the wombe is more direct, it cometh to passe that at once couering for the most part they holde as we vse to say, which is not so betwixt reasonable creatures. Againe, beastes are quiet in that action, being so taught by Nature, for motion often preuenteth conception.

Now, if at the same time both sexes yeelde their seed, then is the conception sooner, and also more perfect, because the wombe at that time being as it were enraged, doeth more greedily draw and more narrowly embrace the seede which is cast vnto it. This *Hippocrates* acknowledgeth in his first Booke *de morbis Mulierum* in these words; *If that which proceedeth from the man, doth together and in a right line concurre and meete with that which is auoyded by the woman, then doth the woman sooner conceiue*, he saith *ἡ δὲ γυνὴ*. by a Metaphor taken from Water-men, who together do arise vpon their Rowers, together dip them in the water, and together driue their stroke. And whereas he saith that they sooner conceiue, it is an argument that it is not of absolute necessity vnto generation, that both sexes should at one and the same time yeeld their seeds; but that there may be conception though it bee slower, if one come a little before or after another; but if the distance of time bee too great between them then the conception succeedeth not, because the spirits of the first seede are exhausted and dissipated before the second ariue vnto it.

The same thing hath *Aristotle* in his tenth Booke *De Historia Animalium*, vpon which *Scaliger* hath written an excellent Commentary, as that mirror of Learning did all things excellently: There are (saith he) that thinke, there can be no conception vnlesse the seeds of both sexes do at the same time meete one with another; these are deceiued, because the better habited body sooner yeeldeth, wherefore that seed being the stronger, is not corrupted but reteineth his spirits, and being drawne by the wombe, is retained for the future permixtion, so that to conception simply this concurrence of seeds at one and the same time is not absolutely, but to a sooner conception it is necessary.

It is also demanded, whether conception may bee without pleasure. On the mans part there is no question, but on the womans; for you shall heare many say that they haue no sense or inkling of pleasure at all. *Dianus* is of this minde that conception is not alwaies with pleasure on the womans part; but *Diana* were a better iudge of this controuersy: let vs heare his reason, because sometimes (saith he) the seede is immediately eiaculated into the bottom of the womb which is of a duller sense, neuer touching the orifice whose sense is more exquisite. A pretty shift I promise yon, but the good man was in an error. For pleasure is not therefore conceiued because the seede toucheth the orifice of the wombe, but because it runneth through the spermatieall vessels of the woman which are of exquisite sense, otherwise women with childe who eiaculate their seed not into the inward orifice, but into the middle of the necke of the wombe, should haue no pleasure in such eiaculations; but it is manifest that they haue greater pleasure after they bee with child then before, because their seed passeth a longer course, as we shall say more at large in our Discourse of Superfoetation.

Hippocrates in his Booke *de Principijs* assoileth this question. For after hee hath giuen vs some signes of conception he saith, that these do not happen to all women, but vnto those onely whose bodyes are pure and cleane; but where the body is grosse, full of mucous and impure humors, there are no such signes. That is to say, an impure, mucous and moyste woman may conceiue without pleasure, or any sence of titillation at all.

Finally, some doubt whether the permixtion of the seeds bee requisite to conception, because it is absurd to thinke that species or kinds are mixed: againe, if they be mixed then should essences be intended and remitted, which in Philosophy is a grosse absurdity, because euery essence is impartible. Likewise of two beings by themselves, one being by it selfe cannot be made. But we answer, that the Seeds being not actually animated, they doe not of themselves make the species of the Creature. If it bee granted also according

o *Aristotle*, that they are imperfect essences or beings, it is necessary that they should bee mixed,

mixed, otherwise they cannot bee nourished or animated together, as Hippocrates sayeth in his Booke *de Natura pueri*. And in his first Booke *de diata*, he blameth them that doubt whether of two fires a third may arise. If any man saith he, deny that a Soule is mingled with a Soule, that is, one seed with another, let him be held for an Idiot in Physicke. And in the very beginning of his book *de Natura pueri*. If the geniture proceeding from both the parents be retained in the wombe of the woman, they are presently mixed into one. And thus much of the effusion of the seeds of both Sexes, the pleasure thereupon conceived, and the permixtion of the seeds themselves.

QUEST. XII.

Whether the wombe haue any operative or active power in the conformation of the Creature.

A double agent.

I will not be hard to untie this knot. According to the Philosophers rule there is a double agent, one Principall another Helpfull or assistant only. A principal agent no man will say the wombe is, because then a woman could conceiue alone without the helpe of the man, and besides Females onely, Males neuer should be formed. The wombe therefore worketh as *Causa sine qua non*, a cause not so much of the being, as without which it could not be; because it awaketh and stirreth vp the sleepey and hidden vertue of the seede. The Physitians make three kindes of Efficient causes. Principall, Helping, or that without which a thing cannot be done.

3. kinds of Efficient causes among Physitians.

How many wayes the wombe worketh. First by traction.

So in Purgations the principall cause is the propriety of the medicine, the Helping cause is the hot Temper; the cause *sine qua non* is our naturall heate, without which the power of the medicine being drowfie would neuer be brought into act. So in the conformation of the Infant, the principall cause is the Seed, I meane the spirits of the seed, by which as by workemen the Soule which is the noble and chiefe Architect frameth a mansion fit for the performance of her different functions. The Helping cause is a laudable Temper of the seeds and of the wombe. The *Causa sine qua non* is the wombe. For because the seeds are not actually Animated but onely potentially, they need another principle whereby their power may be brought into act: the wombe therefore worketh diuerse wayes. First of all it draweth the Seede of the man through the necke, no otherwise then a Hart draweth a Snake by his nosethrilles out of the earth. For the seed is not powred into the cavity of the wombe as some of the Auncients thought, but into the necke thereof. The bottome therefore of the wombe meeteth with the Seede halfe way, and with his inward mouth as with a hand it snatcheth it vnto it selfe and layeth it vp safely in her bosome. And euen as, sayeth Galen in his first Booke *de semine*, a hungry stomacke runneth with his bottome euen vnto the throate to snatch the meate out of the mouth before it be halfe chewed; so the wombe which is the very seat of Concupiscence, being desirous and longing after the seed, moueth it selfe wholly euen to the priuities, and this is the first action of the wombe, to wit, the traction of the seed of the man.

2. By mixtion.

The second action of the wombe is the permixtion of the seeds; now they be mixed either by themselves or by another; not of themselves because they are not alwayes auoided at the same time, as we haue in the question before going proued out of Hippocrates and Aristotle; neither yet are they eiaculated into the same place, for the mans seede is cast into the neck of the womb, the womans into the sides of the bottome which we call the horns of the wombe: the wombe therefore maketh this permixtion of the seeds which the Barbarians call *Aggregation*.

3. By retention.

The third action of the wombe is the Retention of the seeds, in which the woman feeleth a manifest motion of the wombe: for it gathereth, crumpleth and corrugateth it selfe, and so exquisitely shutteth his orifice that it will not admit the poynt of a Probe.

4. By conception.

The last action of the wombe is the suscitation or raising vp of the facultie of the seedes which wee commonly call Conception. Now the faculty of the seed is rayfed or rowfed, not so much by the heate of the wombe as by his in-bred propriety, for if the seede should be cast into any other part of the body though it were hotter then the wombe, it would not be conceyued but putrified.

After Conception the action of the wombe ceaseth; the whole proceffe of the worke of Nature, in forming, nourishing and increasing is left vnto the Infant: this one thing the wombe performeth, it conteyneth, preserueth and cheriseth the Infant, because the place is the preseruer of that which is placed therein.

QUEST.

QUEST. XIII.

Of vitious or faulty Conceptions, and especially of the Mola.

THat Conception is made by the in-bred propriety of the Wombe, this among the rest manifestly prooueth, that into what part of the body soeuer, sauing into this, the seede is powred, this power or efficacy is neuer stirred vp, neither commeth into act; so that conception is as properly the action of the wombe, as Chylification is the action of the stomacke. But that conception may be perfect, the seede which is yeelded and retained must be pure and fruitfull. By pure I vnderstand with Hippocrates, that which is not sickly or diseased, neither yet mingled with blood. For blood is not requisite to generation til after the description of the spermatical parts is begun; otherwise the seed being choaked by the abundance of the blood, neither at all attempteth his worke, neither can it bring to perfection that it could haue well begun. Againe, if the seeds be vnfruitfull, what hope can there be of a harvest?

To perfect conception there is further required an *εὐκρασία* or lawdable temper of the wombe; for those whose wombes are either hot or colde, or moyst or dry above measure do not conceiue as saith Hippocrates. If therefore any of these things be wanting, wee cannot hope for a lawfull conception, but either there will bee none at all, or a depraued and vitious, such as is of the Moone-calse or Mola. For Nature rather endeauoureth an imperfect and depraued Conception then none at all, because she is greedy of propagation and diligent to maintaine the perpetuity of the kindes of things: wherefore rather then she will do nothing, she will endeavour any thing how imperfect soeuer. So when Nature maketh wormes in the stomacke and guts, she doth better then if she should generate nothing at all, because of a thing immoueable she maketh a thing moouable by it selfe, and of it selfe, and of a putrid and rotten humour an animated creature.

The nature and causes of this faulty conception which they call the Mola or Moon-calse we will endeauour to finde out. The Mola the Grecians call *μολή* or *μολισμός*, some thinke that the name came from a Bakers Mill, because it is like thereto both in hardnesse and in roundnesse. Among the Persians the word *Moli* signifieth a deformed thing. *Affranus* the Poet calleth it *Molucrum*, *Aristotle* often *Μόλυσμα*, because it is like a parboyled thing. Wee call it *A Moone-calse*. *Galen* in the 7. Chapter of his 14. Booke *de vsu partium*, defineth a Mola to be *σάρκα ἀργήν καὶ ἀδιάπλαστον*, that is, an Idle and imperfect flesh. But this definition dooth not expresse the whole Nature of the Mola. For there may bee a rude flesh generated without motion, which is not a Mola. There are euery where Caruncles generated, which no man will call Moles. We think that this rather is a perfect definition of a Mola. *The Mola or moone calse is an idle flesh without forme and hard, engendred onely in the wombe of a woman, and that of weake seede, which seede vnder taking the Conformation, but beeing oppressed or stifled with abundance of blood, it cannot attaine his owne end, and therefore in steade of a creature generateth a lumpe of flesh.*

The particular parts of this definition we will discourse of and discusse in order. The Mola is a flesh, because his substance is fleshy and red like clodded blood. It is Idle, that is, without any Animall motion; for it is not at all moued vnlesse it be after the motion of the wombe. It is rude without forme, not that it wanteth his owne forme, for it hath as saith the Philosopher his owne being, but it hath neyther *εἶδος* nor *μορφήν* that is, neither the species nor the former of a creature. It is engendred onely in the wombe of a woman, because as writeth *Aristotle*, onely a woman hath abundance of menstruall purgations, for that her diet is moist, and her course of life sluggish and idle in respect of other creatures. That which is objected of the Beare which alwaies bringeth foorth her young rude and vnformed, and perfecteth them by licking, either we say it is a Fable, or else that their young doe appeare deformed or vnformed but are not so indeed, but because they lurke all winter in the caues of the earth, they are couered with a slimy & Flegmaticke moysture which the Dam licking off makes their proportion appeare.

The rest of the parts of our definition, doe fully declare the manner of the generation, and the causes of the Mola. I know there are diuers opinions of the Ancients concerning their generation. *Plutark* saith, that a Mola may be generated without the cōpany of a man, whom many follow, who thinke it may be generated only of the seed of the woman, when

to it a great quantity of her blood accrueth. But this opinion is disprooued by *Galen* in the 7. Chapter of his 14. Booke *de usu partium*, where hee saith that among all creatures which walke continually vpon the earth, none doe euer conceiue without the seede of the Male, no not a faulty or vitious conception; because all beginning of conformation proceedeth from the seed of the Male as that which is the first principle of Generation. Addhereto that if a *Mole* could be conceiued only of the seed of the woman, then those Virgines which doe suffer nightly pollutions might conceiue the same, which neuer yet was heard of.

Mercurialis,
his opinion.

Refuted.

Hippocrates
opinion.

The Coagmentation therefore of the *Mole* is neuer made without copulation. Some thinke that the *Mole* is generated as other flesh, onely by the affluence of abundance of blood which is gathered or caked together by the heate of the wombe. But because the blood hath no aſtiue or operative power but onely paſſiue, I doe not see how a *Moale* can be made onely of blood; when as we see it is tyed with ligaments to the wombe and inuested with membranes, which ligaments and membranes are the rudiments of a conformation inchoated or begunne. Neither are wee to giue credite to them that affirme that it is generated onely of crude and corrupted seede, or when the seede of the woman ouercometh the Seed of the Male. The true manner of their Generation *Hippocrates* setteth down in his first Booke *de morbis mulierum*, which, because we esteeme it as an Oracle, I will here transcribe. *Concerning the Conception of the Mole this is the very truth: when a great abundance of blood cloyeth a little ill disposed seed, there cannot bee a lawfull conception, yet the belly swelleth as if the woman were with Child.* What could be sayed more succinctly, what to better purpose?

Explained.

Two things he requireth to the Generation of the *Mola*: First that there be the Seede of the man; but that in little quantity and vitious or faulty. Secondly that great quantity of blood should flow vnto it. That little and vitiated seede vndertaketh the worke of conformation and beginneth to forme the membranes; for almost all Moone. calues are couered with filmes and membranes.

The manner of
the generation
of the mole.

But when as the seede thus little and weake endeuoureth to perfect his woorke hee hath begun, then is the discretion or separation of the parts hindered and interrupted by the affluence of too much blood, & the Conception becommeth illegitimate, because the blood beareth greater sway then the seede; so that in steade of a living Creature which was the first intention of Nature, there is generated an vnformed and rude masse of flesh hauing indeede the principles of Life, but those so weake that they are presently suffocated and extinguished. For whereas it dayly groweth and encreaseth, that commeth not by true nutrition but by apposition onely. Some thinke that this flesh is not altogether without life, but iust as if they should say it had halfe a Soule.

Aetnarius definition.

It is therefore *Hippocrates* resolution that the *mola* can neuer bee generated without the seede of the man, and that the beginning of the coagmentation or gathering of the same is alwayes from that same seed. The very same thing *Aetnarius* confirmeth by this definition. *The Mola* sayeth he, *is a fleshy tumor which hath his beginning and his firmnesse or fastnesse from prolificall Seede.* And thus much shall haue bene sufficient to haue sayd of the Nature and cause of the *Mola*.

The signes to
distinguish a
mole from an
Infant out of
Hippocrates.

The tumor of
the belly.

The motion.

Now let vs acquaint you by what notes and signes it may be distinguished from a true Conception. *Hippocrates* in his first Booke *de morbis mulierum*, and in his Book *de Sterilibus*, conceiue that the signes of the *Mola* are fetcht from these foure. The tumor or swelling of the belly, the motion, milk & the time of the gestation. For the first, the belly sooner swells vpon the conception of a *Mola* then of an Infant; beside, it is stiffer stretched and carried with more difficulty. For the motion; if after the third and fourth moneth the woman feele no motion the Conception is faulty; for sayeth *Hippocrates*, Male Infants do moue the third moneth and Females the fourth.

But the *Mola* is altogether immouable vnlesse it be accidentally moued together with the wombe: and if a woman in that case feele sometimes a trembling and panting motion, wee say it is not so much caused by the *Mola* it selfe, as from the wombe which strueth to shake off so vnprofitable a burthen. Beside, the motion of the *Mola* and the Infant is altogether vnlike: for the Infant of it owne accord turneth himselfe and mooueth euery way, the *Mola* like a bowle or vnwealdy bulke is rowled to the right side or to the lefte as the womb doeth incline to either hand. A *Mola* pressed with the hand giueth way instantly, but presently returneth thither againe: the Infant as it yeeldeth not presently, so after it hath giuen way it returneth not into the same place and position againe.

The

The third signe of the Mole Hippocrates taketh from the nature of the Milke. *This is the greatest and most certaine argument of the Mola, if there appeare no Milke in the Pappes.* But if the Conceptions be legitimate, there is Milke. For this we haue a golden saying in the Booke *De Natura Pueri*, *As soone as the Infant beginneth to moue, even then the Milke bewrayeth it to the Mother.* But if a Mola be conceived, there is no Milke generated. Amongst all the rest, there is indeed no signe so infallible as that which is fetched from the time of the Gestation. For, if the Tumor of the Belly continue after the eleuenth month, which is the utmost limit of gestation, and yet there appeare no signes of a Dropsie, we may be bold to say, It is not an Infant but a Mola that is conceived. And Hippocrates saith, *That a Woman may beare a Mola two yea three yeeres.*

Three signes from the milke

Hippocrates

Aristotle also in the seventh Chapter of his fourth Booke *De Generatione Animalium* saith, that a Mola may endure in a Womans Body foure yeeres, yea the whole course of her life, so that she may grow old with it, yea and dye with it of another disease. And in the tenth Booke *De Historia Animalium* he rendreth the reason, *Because (saith he) being no Creature it vttereth not the wombe neither moueth therein as doth the Child, who by kicking seeketh a way out for himselfe.* Moreover, the Mola breatheth not, neither needeth any aire at all, and therefore seeketh not passage for it.

A Mola may lye long in the wombe and why.

The late Writers add, that the Woman which hath conceived a Mola becommeth pale, looseth all her colour, yea and pineth away in her whole Body. And thus much of the Mola his nature, and the signes whereby it may be distinguished from a lawfull Conception.

QUEST. XIII.

Of Monsters and Hermaphrodites.

O depraued and illegitimate Conceptions must Monsters be referred, concerning which, it shall not be out of our way to giue you some brieue notice. Monsters Aristotle calleth Excursions and Digressions of Nature, taking his Metaphor from Trauellers, who wander out of their way yet goe still on their intended iourney. For when Nature cannot accomplish and bring to perfection that she intendeth, least she should be idle, which is a thing incompetent to her disposition, she doth what she can. And in the second Booke of his *Physickes*, he defineth a Monster to be a fault, or error, or preuarication of Nature working for some end of which she is frustrated because of some principle corrupted.

The definition of a Monster.

Monsters happen many wayes, and there are of them innumerable differences. We will onely handle the chiefe in this place, because haply in another worke we may be in this kind more particular. Monsters happen either when the Sex is vitiated, or when the Conformation is vnlawfull. In the Sex, when they are of an vncertaine Sex, so that you may doubt whether it be a Male, or a Female, or both, as Hermaphrodites. By-sexed Hermaphrodites they call *Androgynas*, *ἀνδρῶν καὶ θηνῶν*, *ἀνδροθῆνας*. In Males that commeth to passe three manner of wayes. When in the *Perinaum* or *Interfaminium*, that is, the place between the Cod and the Fundament, there appeareth a small Womans Priuitie: againe, when the same hapneth in the Cod but without any auoyding of Excrement by it: and thirdly, when in the same place the Vrine issueth. In Females there is but one manner, when a Yard or Virile member beareth out in the bottome of the Share-bone about the top of the Genitall in the place of the *Clitoris*. Some add in Men, when there appeareth a small Priuitie of a Woman about the root of the Yard. In Women, when a Yard appeareth at the Leske, or in the *Perinaum*.

The differences.

Monsters in Sex.

How many kinds of Hermaphrodites

In Conformation Monsters are more ordinarie. To Conformation we referre Figure, Magnitude, Scituation and Number. In Figure Monsters happen: if a Man haue a prone or declining Figure like a brute Beast, if he haue the Face of a Dogge, of a Wolfe, a Fox, a Toad, or such like. In Magnitude exceeding or deficient: if there be an vnequall proportion of the parts, as a great Head, or againe, so little that it agreeth not with the rest of the parts. In Scituation, as if the Eyes be in the middle of the Forehead, the Nofethrils in the sides, the Eares in the Nowle, or such like. In Number exceeding, as when it is diuided into two Bodyes, two Heads, foure Armes, or such like: or deficient, if it haue but one Eye, no Eares, and the like.

The difference
of Monsters
from the
Efficient.

A History.

Concerning the causes of Monsters, diuers Men are of diuers minds. The Diuine refers it to the iudgement of God: the Astrologers to the Starres: *Alcabitius* saith, there are certaine degrees in which if the Moone be when a Child is conceived, the birth becommeth monstrous. We list not to exclude the iust vengeance of Almighty God, which no doubt hath a great stroake in these things: but to speake as a Physitian or naturall Philosopher, it must be granted that all these Aberrations of Nature are to be referred vnto the Materiall and Efficient causes of Generation. The Matter is the Seed, the Efficient or Agent is either Primarie or Secundarie. The Primarie or principle cause is double. The formative Faculty and the Imagination. The Secundarie is the Instrument, to wit, the place and certaine qualities as heat. The Matter is in fault three wayes. For it is either Deficient or Abundant, or is diuersly mixed. If there be want of Spermatick matter, then the Monster is deficient either in Magnitude or in Number. If there be ouer-plus of Seed, they become double headed, with foure Armes, &c. If there be a confused permixtion of the Seed, then are Monsters generated of diuers kinds: as vpon Sodomie and vnaturall copulations of Men and Beasts horrible Monsters haue been brought into the World: so *Aristotle* saith, that in *Egypt* and *Africa* where Beasts of diuers kinds meet at the Waters of *Nilus*, or in the Desert-places and mis-match themselves, there are often many Monsters generated. And thus come Monsters arising from the Matter. From the Agent or Efficient Monsters may happen diuers wayes. The Primarie Agent as we said, was either the formative Facultie or the Imagination. The power of the Imagination we shall shew a little after in a fitter place, here it shall be sufficient to shew out of the learning of the *Arabians*, that a strong Imagination is able to produce Formes even as (say they) the superiour Intelligences in the Heauens doe produce the formes of Mettals, Plants and Creatures. We read that in the precinct of *Pisa*, a Woman brought forth a Female Child full of Haire like the Haire of a Camell, because (saith the Author) she was wont to kneele before the picture of *Iohn Baptist*, clothed in Camels Haire.

The Secundarie Agent is the Heat or the place of Conception. Heat hauing a fierie mobilitie or quicke motion, formeth sundry shapes of Bodies and worketh the Matter into diuers fashions. The peruerfion also, or the euill Conformation of the place, that is, of the Wombe, may be the cause of a depraued Figure. And thus I make an end of this common place at this time, wherein my purpose was onely to touch the heads of things, reseruing my selfe to hereafter for the particular prosecution. Hitherto we haue intreated of the difficulties which might arise concerning the Conception, now it followeth concerning the Conformation.

QUEST. XV.

Whether all the Parts are formed together.

The difficultie
of the
Question.

His Question is so hard and full of obscuritie, that *Galen* saith it is onely knowne to God and Nature. For what is more diuine then the first conformation of a Man? What more admirable? What more secret? This the kingly Prophet inspired from aboue acknowledgeth, *I will confesse before thee, O Lord, because I am wonderfull made, thy eyes saw me before I was shaped, &c.* Seeing therefore the resolution of this Question is aboue the reach of humane capacitie, which God wot is circumscribed within verie narrow limits: if to make some ouerture thereof I shall take a little more libertie to my selfe, I desire all those that desire with me herein to be informed, not to impute it to my wandring wit, but to the greatnesse of the Subiect. Because therefore as by the Collision of Stones Fire is beate out, so by the ventilation or skirmish of aduersarie opinions the truth comes best to be knowne, we will first with your patience see what the Ancients haue conceived of this matter.

Alcmaeon's
opinion

Alcmaeon thought, that the Braine was first of all formed because it is the seat of Reason and the habitation of the Soule, as also for that in Infants the Head is greater in his proportion then any other of the parts. It may be he had read in *Hippocrates* his *Epidemia*, that the magnitude of the Bones and of all the parts is to be esteemed according to the magnitude of the Head, as if all the rest were formed by the Head, and had dependencie therefrom.

Galen

Galen in the second Chapter of his sixth Booke *De Placitis Hippocratis & Platonis* remembreth that *Pelops* taught publikely that all the Vessels had their originall from the Braine: the same also was the opinion of that *Persian* Philosopher whom *Anicen* calleth *Thesius Perseus*: others *Syamor Cabronensis*.

Pelops.
Theſeus or Syamor.

But because the Braine is onely the Author of sence and motion and the principall Faculties which the Infant hath no need of in his first Conformation, I see no reason why the Braine should be formed before the other Spermatieall parts.

Democrat as *Aristotle* saith in the first Chapter of his second Booke *De Generatione Animalium*, did thinke that the outward parts were first formed, and afterward the inward parts, as Artificers are wont first rudely to frame the modell of Creatures in Wood or Stone before they cut out the more curious lines. *Orpheus* thought that a Creature was formed as a Net is knit, that is in order: *Empedocles* that the Liuer was first formed: the *Stoicks* all the parts together. *Aristotle* in his second Booke *De Generatione Animalium* saith that the Heart is first of all formed, and by and from it all the parts are produced, which (as a Child enfranchised by the Father) taketh vpon him to rule and dispenche the whole Body. This saith he is the first and onely principle, the first liuer, the first mouer, the first that maketh Blood, because it dyeth last of all; now that that dyeth last liueth also first. That the Heart dyeth last, beside that we are taught it by daily experience, *Galen* also confesseth as much in the first Chapter of his sixth Booke *De Locis Affectis*, *Death neuer followeth* (saith he) *vnlesse the Heart be first affected with an immoderate dissemper*. It is therefore necessarie that the Father or Lord of the Family which is the Heart, should be created before the Cater or Steward which is the Liuer. This opinion of *Aristotle*, *Anicen* the Prince of the *Arabian* Family seemeth to follow, which also he establisheth by some reasons: because the Creature cannot be nourished vnlesse he liue and participate of the influence of heat, now the Heart is the plentifull Fountaine of naturall heat.

Democrat.

Empedocles.
Aristotles.
opinion.

The Heart
dyeth last
after *Galen*
and *Aristotles*

Anicens opinio
on.

Againe, in the first dayes after Conception the formative Facultie needeth no nourishment, because there is no notable resolution or expence in the parts: but of heat and vitall spirits there is alwayes need, therefore it was necessarie that the Heart should be formed before the Liuer.

But this opinion of *Aristotles* is long since cast out of the Schooles of Physitians: For that it is not the onely, nor the first principle we haue already proued sufficiently in the second Question of the Controuersies of the first Booke. Now that it is not first generated may be demonstrated both by Reason and Sence, which two are the most vnpartiall Iudges of all Controuersies. By Sence, because there alwayes appeare together and at once three bubbles, which are the rudiments of the three principall parts, neither did any Man euer obserue one of those bubbles onely. By Reason, because in the first dayes after Conception the *Embryo* needeth not the helpe of the Heart. For liuing the life onely of a Plant, it needeth neither pulsation or spiration nor the influence of heat, because it cherisheth himselfe with his owne heat and with his owne inbred spirit. And whereas *Aristotle* would conclude it to be the first that liueth, because it is the last that dyeth, we say that followeth not: For those things that are first in Generation are not alwayes the last in Dissolution.

Aristotles
opinion.
confuted.

By Sence.

By Reason.

So in the Generation of any thing that is mixed, the Matter goeth before the Forme, and yet the abolition of the Forme is the corruption of the thing mixed. By this reason also in Snakes and Serpents the Taile should be that which liueth first, because when all the other parts are starke dead and immouable, yet the Tayle liueth and moueth. We thinke indeed that the Heart is last of all deprived of life, because when the Infant is perfected and absolued the vitall heat floweth onely from the Heart as from a most plentifull Fountaine; but that it first liueth we vtterly deny: because to liue is either to be nourished or to be animated. The Heart is neither first nourished nor first animated. All nourishment is by Blood, Blood is not but by the Veines, all the Veines are from the Liuer, and the Vmbilicall Veine which is the first Nurse of the *Embryo* poureth the Blood into the *Parenchyma* of the Liuer before that of the Heart. Neither is the Heart first animated because the Seed when it breaketh into act, i. when it beginneth the conformation is wholly and actually animated. Therefore all the parts thereof doe actually liue onely by the participation of heat in the moisture. We bid therefore adue to *Aristotle*, *Chrysippus*, the *Stoicks* and whosoeuer else doe thinke that the Heart is the first liuer and the first maker of Blood.

That the heart
doth not first
liue.

What it is
to liue.

Galen seemeth to differ from himselfe in the order of the Conformation of the parts, for sometimes he saith that the Heart and the Liuer are formed together, sometimes that

Galen in this
isdeters.

The parts are
generated
successively.

the Liuer is first formed, sometimes that the Vmbilicall Veine hath the preheminence, yet herein he is alway of one mind, that he thinketh the parts are generated in succession, not at once and together. And this he illustrateth by examples of those things that are wrought by Art. For a House is not built all at once, but first the Foundations are layd, then the Walls are reared, and finally the Roofe is layd on: so saith he it is in the Infant, one part is formed before another, to wit, that first which is most necessarie for the *Embryo*: and that he thinketh is the Liuer, because the Infant liueth at first the life of a Plant needing onely nutrition as doth a Plant: now the Liuer is the Shop or Storehouse of Aliment. As therefore a Plant hath no need of a Heart, so neither the Infant in the beginning.

Galen.

Moreover that the Liuer is first generated may be proued by the magnitude and the facilitie of his generation, for it is made onely of congealed Blood: add hereto that the Vmbilicall Veine attaineth to the Liuer before it commeth to the Heart. That all these things are true *Galen* teacheth in the third Chapter of his Booke *De Formatione Fetus*, because in Infants the naturall faculties (as being the first of all other) are the strongest, those that rise from the Heart much weaker, those weakest of all which come from the Braine. Furthermore all Generation proceedeth from that which is more imperfect to that which is more perfect: wherefore first is the Liuer generated, then the Heart and last of all the Braine. This is the opinion of *Galen* and almost of all Physitians both old and new concerning the conformation of the parts.

Galen's

opinion

not to be

approved.

The Reasons.

We for our owne part doe not vse to sweare vnto the opinion of any Man, but as we esteeme much and haue in great reuerence the Patrons and Founders of our Art, as becommeth vs well: so if at any time they stray from the rule of right Reason, we shall not make scruple to dissent from them. Whatsoever therefore *Galen* may thinke, we cannot be perswaded that the Liuer is first formed, because before the delineation of all the parts of the Infant he needeth not the helpe of the Liuer; for it was not behoofefull that the Blood should flow till after the discretion and description of the Spermatieall parts, otherwise the Seed would be cloyed and clogged with Blood and in stead of a lawfull Conception a *Mola* would be formed.

As for that nourishment and increase which *Galen* feigneth should be made by the Blood, we are so farre from thinking it necessarie to the first conformation, that we rather thinke with *Hippocrates* and *Aristotle* that it would haue beene a great hinderance thereto, so that we may retort *Galen's* weapon which he vseth against *Aristotle* vpon himselfe. The Infant saith *Galen* needeth not the helpe of the Heart, therefore the Heart is not formed before the Liuer. We say, the Infant needed not the helpe of the Liuer because it is not nourished till after the delineation of the Spermatieall parts is absolued, wherefore the Liuer ought not to be formed before the Heart and the Braine.

Obiection.

You will obiection for *Galen* that life is limited and defined by Nutrition, if therefore the *Embryo* doth liue it needeth to be nourished.

Solution.

I answer, that in Creatures that are perfect nothing liueth that is not nourished, but imperfect Creatures and such as are without Blood may liue a time without nourishment, so some Creatures liue all Winter in holes and a Plant all Winter is not nourished, but viui-fieeth and quickneth it selfe. The tender *Embryo* therefore which is without Blood liueth the first dayes and yet is not nourished, because there is no necessitie of nourishment seeing there is no exhaustion of the parts.

What we

thinke.

It remaineth now that we make manifest vnto you our owne conceit of the order of Conformation, which we will doe as briefly and perspicuously as possible we can: But because we would haue euen the most ignorant conceiue vs the better, we will vse first these distinctions.

Differences
of the parts
of the Infant.

Of the parts, some are proper to the Infant it selfe of which it hath vse in the whole course of his life: others are seruiceable vnto it onely so long as it abideth in the Mothers Wombe, of which kind are those skinny couerings and small Membranes compassing the Infant about. Againe, we must obserue thus much, that some parts are Spermatieall engendered of the Crassament of the Seed, others Fleshy whose originall is immediately from the Blood. And of these Fleshy parts there are three kinds, as there are three kinds of Fleish. For it is either the Fleish of the Bowels which we call *Parenchyma*, or the Fleish of the Muscles, which *Hippocrates* properly and absolutely termeth *carx*, that is, *Fleish*, or the peculiar Fleish of euerie part which hath not any proper name.

The Mem-
branes first
generated.

These things being thus, we conceiue, That the Membranes called *Amnion* and *Chorion* are

are first of all formed, because the inward and most noble part of the Seed was to be defended and walled about with these Curtaines, as we shall shew more distinctly in our next exercise.

These Coats being formed, we thinke that the rudiments or *Stamina* and threds of all the Spermatieall parts are formed together at once, because the Matter is the same, alike altered and disposed by the heat, the Workeman the same, to wit, the spirit diffused through the whole masse of the Seed; the Finall cause the same, that is, the vse of euerie singular part. For, seeing that in the first delineation the Infant needeth not either the nourishment of the Liuer, or the influence or pulsation of the Heart, or the sence of the Braine, but cherisheth it selfe with his owne in-bred heat; why should we thinke that one of the parts is formed before another? If Nature when she vndertaketh the concoction of Quitture or *Pus*, which we call Matter, doth bring the whole to an equallitie together, and insinuates it selfe equally and alike into all the parts thereof; why shall she not in this first delineation of the Spermatieall parts (the Idea of all which the Formative Facultie containeth in it selfe) begin and accomplish the description of all of them together? Neither is this our opinion, but the Conclusion of *Hippocrates* in his first Booke *De Dieta*, and in his Booke *De Locis in Homine*. In his Booke *De Dieta*, *The parts are all delineated together, all together increased, not one or more, before or after another or the rest, but those that are greater by Nature doe appeare before those that are lesse.* In his Booke *De Locis in Homine*, straight after the beginning he breaketh out into these words, *It seemeth vnto me, that there is nothing first in the Body, but all things are the beginning and all things the end, all parts first and all last.* What could he say more plainly? What more briefly? Or what indeed could be either spoken or imagined more Diuine?

All the parts formed together.

Hippocrates opinion.

The Flethy parts are the last made, and their order.

The Spermatieall parts therefore which we call Solid or first parts, are shadowed or lined out at once and together, but afterwards they are perfected euerie one in their order; First, those that are more noble and necessarie, and those last which are most ignoble and lesse necessarie. After the delineation of the Spermatieall parts are formed the Flethy, and first of all the *Parenchymata* of the Bowels, next the proper Flesh of the particular parts, and finally the emptie spaces of the Muscles are filled vp.

Among the *Parenchymata* we thinke that of the Liuer is first gathered together, because the Vmbilicall Veine doth first poure the Blood there-into, which being concreted or caked maketh the substance or Fleth of the Liuer; and this *Haply Galen* meant, where he saith that the Liuer is first generated; so that in this sence if he spake, he may well be excused.

How *Galen* may be excused.

QUEST. XVI.

Whether the Membranes which incompasse the Infant be first formed, and whether they be made by the Forming Facultie, and of the Seed of the woman.

Concerning the originall of the Membranes which compasse the Infant, three things are to be enquired after. First, whether the Formative Facultie doe at these begin the Conformation, that is, whether these be first of all formed. We thinke that they are, being taught both by Reason and Experience.

Three Questions. The first. That the Membranes are first formed. Experience.

For Experience, we will auouch *Hippocrates*, *Aristotle*, *Galen* and our owne. *The Geniture*, saith *Hippocrates*, *after it is mixed and retained, what day or houre soeuer it be added, doth alwayes appeare couered with a Filme or Crust.* The same writeth *Aristotle* in his Booke *De Generatione Animalium*. And *Galen* in his first Booke *De Semine*, *I haue often seene the Geniture conceived onely couered with Membranes.*

Who euer saw a Conception, although it were vicious and illegitimate which was not couered with a Filme as it were with a Garment? The *Mola* albeit it be verie rude and without forme, yet it is cloathed with a Membrane, a manifest argumen, that the Formative Facultie in all Conceptions beginneth her worke with the delineation of the Membranes, though she be hindred that she can proceed no further.

To Experience we may add Reason. The Membranes were necessarily first to be made, that the Seed herein being encompassed might the better manifest his operations, as all that the inward Spirits thereof might be kept from Dissipation and vanishing away, and that the tender *Embryo* might not hurt his soft sides against the hardnesse of the Wombe.

The second
Question.
Whether the
Membranes
are made by
the Formative
Facultie.

Authoritie.

Reasons
against it.

Our resolu-
tion.

The Authori-
tie expounded

The Reason
answered.

The third
Question.
Whether the
Membranes
are generated
of the Mans
Seed or of the
Womans.

The resolu-
tion.

Arantius his
false opinion.

The second Question is more obscure and the more knurrie knot a great deale to riuē, which is, whether these coverings be made by the Formative Facultie? Some thinke that they are generated onely by the heat of the Wombe, and for their opinion doe vrge *Hippocrates* Authoritie and Reasons. For, in his Booke *De Natura Pueri* he writeth: *That the Geniture being heated and puffed is compassed with a Filme, euen as Bread when it is baked is compassed with a Crust.* Now the Crust of Bread or such like is rayfed in the superficies of the Masse onely by the heat of the Fire.

His Reason is on this manner. The Seed containeth in it selfe the *Idea* or Forme onely of those parts from whence it floweth; but in neither of the Parents are there any such Membranes; how then shall the Seed haue any power at all to make or forme them?

But we thinke that the three Membranes are generated by the Forming Facultie of the Seed, and not by the onely heat of the Wombe, because there is no such great heat in the Wombe which in so short a time can burne or puffe the superficies of the Seeds into such Membranes. For if the Wombe should attaine vnto that degree of heat, surely there would be no Conception. So saith *Hippocrates* in his Aphorismes: *Those women who haue hot Wombes doe not conceire*, because when the Wombe is too hot, the Seed is baked and torried as it were.

As for the aboue alleaged authoritie of *Hippocrates*, it maketh nothing against vs; for he doth but illustrate an obscure thing by a similitude or comparison: as if he should say, Euen as the Bread is compassed with a Crust, so is the Infant compassed with Membranes: but that the manner of the generation of these two is alike, that he doth no where affirme: and whereas they say that the Seed containeth onely the *Idea* or Forme of those parts from which it issueth, and that there are no such Membranes actually either in the Father or in the Mother: I answer, that such and so diuine are the powers of the Forming Facultie, that they can diffuse or transfuse themselves out of one Seed into another. If therefore the markes which were in the Body of the Grandfather doe often appeare in the Grandchild, yea in his Posteritie after many degrees of consanguinitie; why shall not the Forming Facultie of the Fathers Seed make an impression in the Infant of that power which the Father himselfe had when he was Seed? Add hereto the necessitie of the Finall cause. For it was behoouefull that the Infant should be inuested with Membranes, and therefore the noble and absolute Architect hath made them.

The third Question which we haue here to discusse, is, Whether these Membranes be generated of the Mans Seed or of the Womans. It is the old receiued opinion, that they are generated onely of the Mothers Seed, because that is the colder and lesse fruitfull, wherefore Nature hideth more inward the noble and especiall parts of the Seed; the more ignoble and base she disposeth on the outside as a defence to the rest: now the Seed of the Woman is more ignoble. Moreouer, the quantitie of the Mans Seed is but little and not sufficient for the forming of the outward and inward parts both, and therefore it prayeth ayd of the Seed of the Woman.

We thinke therefore that for the most part the Membranes are made of the Seed of the Woman, but that they are made onely thereof, that we deny. For if the Seed of the Man be sufficient for the generation of all the parts of the Infant, why should it not also be sufficient to generate the *Chorion*? Again, if the Seed of the Woman doe onely generate these Membranes, how cometh that to passe which *Hippocrates* auoucheth in his first Booke *De Diata*; that when the Womans Seed getteth the victorie ouer the Mans, there are procreated three kinds of Females? Doth not the Womans Seed sometimes ouercome in the permixtion of the Seeds of the Sexes? Therefore when the Womans Seed is stronger then the Mans, why should we attribute the generation of the Membranes vnto the stronger Seed, and of the whole Body of the Infant to the weaker?

We conclude therefore that the Membranes may be generated of either Seed of the Male or Female, but of the Female more ordinarily: and againe that of the Mothers Seed not onely these Membranes but also the Spermatieall parts of the Infant may be formed.

Arantius in the Booke he set out of the Infant saith, that the two Membranes the *Amnion* and the *Chorion* are not generated before all the rest of the parts, but that they are propagations of the inner Coats: the *Amnion* of the Flethy Membrane, and the *Chorion* of the *Peritoneum*. But this is against all experience and reason, as we haue sufficiently shewed in the beginning of this Exercise.

QUEST.

QUEST. XVII.

Of the number of the Vmbilicall Vessels.

IN the Historie of the Vmbilicall Vessels, there are two things obscure, to wit, the number of the Vessels and their originall. Concerning their number the Anatomists are at variance: some say there are onely three, others foure, some five. They which acknowledge three, make onely one Veine and two Arteries. They which would haue foure, add to these three the *Vrachos*. Those who would haue five, number two Veines, as many Arteries and the *Vrachos*.

We resolu, that as well in Men as in Beasts there are foure alwayes, and onely foure to be found. The first is the Veine which is the Nurse of the *Embryo*, which alone & by it selfe arriueth at the Nauell from the Fissure of the Liuer. This Veine, when it hath passed the Nauell is clouen into two and maketh two distinct Channels, and these againe are diuided and subdivided, whose branches being supported by the Membrane called *Chorion*, doe conioyne themselues with the Veines of the Wombe; in Sheepe and Swine by certaine round and Nauell-like Excrecences which they call *Cotyledones* or *Accetabula*; in Women by that bulke of Flesh which the late Anatomists call the Cake or Liuer of the wombe, but I know not for what reason: For I doe not belieue saith *Laurentius* that the Blood is prepared and boyled in that Flesh, but I acknowledge the same vse of it which the Auncients assigned to the Glandulous Body called *Pancreas*, to wit, safely to sustaine and like a Pillow to vnderprop the innumerable propagations of Vessels which are distributed through the *Chorion*. The Veine therefore from the Nauell to the Liuer is but simple and single, which after it is passed the Nauell is clouen in twaine and appeareth double. And thus are the different places in *Galen* to be reconciled, where he writeth sometimes that this Veine is single, sometimes that it is double. The Vmbilicall Arteries are two, one on either side, proceeding not from the Heart but from the *Iliacke* branches of the great Arterie descending. The fourth Vessell remaineth, and vpon this Hinge is the whole Controuersie turned: the Auncients called it *Vrachus*, because by it the Infant poureth his Vrine into the Membrane. Almost all the late Anatomists deny this to be in a Man and say it is onely found in Beasts. Yet I saith *Laurentius*, haue alwayes obserued it euen in Men also: For that a Nervous production is led in Men from the bottome of the Bladder to the Nauell as well as in Beasts, I thinke no Anatomist will deny. I aske therefore what vse is there in Man of this production? Not onely that it may serue for a Ligament (for the Bladder is tyed and doth adhere to the Neighbour parts very strongly by the interposition of many Fibres arising from the *Peritoneum*) but to leade away the Vrine as it doth in brute Beasts? And in this my opinion saith the same *Laurentius*, I am confirmed by the Historie of a Wench whose Vrine being a long time suppressed, did at last issue out at her Nauell. This *Bartholomew Cabrolus* a most expert Chyrurgian, and the ordinarie Dissector to the Colledge of Physitians at *Mompelher* in *France*, hath often made mention of. *Fernelius* also in the thirteenth Chapter of the sixth Booke of his *Pathologia* telleth the like Storie: One there was, saith he, about thirtie yeeres of age in whom the necke of the Bladder was obstructed, and whose Vrine issued plentifully for many months together at the Nauell as it had bene pressed out, and that without any tumor, collection of water in the *Abdomen*, or any offence at all in his health: when many hereat wondered much, and I heard that when he was borne his Nauell was ill tyed and euer after some little quantitie of water issued that way; I conceived that the *Vrachos* was not dryed, and that his Vrine did now as it did when he was in his Mothers Wombe returne from the Bladder to the Nauell.

There are therefore foure Vmbilicall Vessels, one Veine, two Arteries, and the *Vrachus*; all which about the Nauell do meet and are included in a long nervous and writhen Canale like a Gut, which they call the Rope, the Tye, or the Gutling. The reason why they are so incompassed is, that they might not part one from another, and so be either broken being scuered, or intangled if they had scope to intangle themselues. These foure Vessels when the Infant is borne, as now becomming of no vse, doe degenerate into a Ligament. Yet it hath bene obserued that in some after they are growne to good age, the Vmbilicall Veine hath bene changed into a loose and open Veine, as *Volchier Coiser* obserued at *Noriberge* in a Mayden of 34 yeeres old.

QUEST. XVIII.

Of the originall of the Vmbilicall Vessels.

Galen expounded.

Aristotle.

Galen excused.

The opinion of some Anatomists

That the Vmbilicall Veine is not first formed.

What we resolve of.

THE Controuersie is no lesse concerning the originall of the Vmbilicall vessels then it is concerning their number. Some thinke they haue their originall from the Vessels of the Wombe, because they are continuated with them, and are torne from the Infant sooner then from the Wombe. And this same *Galen* seemeth to approue in his Booke *De Dissectione Vteri*. The end of that Vessell which is propagated through the Wombe, giueth beginning to that Vessell which is in the *Chorion*: so that you may see, that these two are one. For they are so vnited by their Mouthes, that the Veine draweth Blood from the Veine, and the Arterie spirit from the Arterie. The same writeth *Aristotle* in the eighth Chapter of his seuenth Booke *De Historia Animalium*: The *Nauell*, saith he, is as it were the Cup of an Acorne about the Veines whose originall is from the wombe; in those Creatures which haue Acetabula from those Acetabula, in those that haue them not from the Veine it selfe. But I thinke *Galen* in the place aboue named tooke more libertie to speake after the common opinion of the multitude not as himselfe thought. For that he might declare the continuitie of the Vessels, he saith, that the end of one Vessell is the beginning of another. A beginning I say not Physicall or Originall, but Mathematicall, that is, Quantitatiue, as the Schoole speakes. Some there are who thinke, that the Vmbilicall Veines and Arteries are first of all generated, and that all the roots of the Veines and Arteries issue from them, because the Veines proceed from the Liuer, and the Arteries from the Heart: now the Vmbilicall Veine is generated before the Liuer; for his *Parenchyma* is not gathered without Blood, and Blood is not deriued but through Canales, and therefore it was necessarie that the Vmbilicall Veine should be formed before the Liuer.

This opinion is indeed verie probable, and so sometimes seemed it to me (saith *Laurentius*) to be, but when I tooke a more serious consideration of the matter, I found it to be otherwise. For how should so many & so notable roots of Veines as are dispersed through the whole *Parenchyma* of the Liuer, arise from so small a branch as this Vmbilicall Veine is? Again, those parts that arise one from another must of necessitie be continued the one with the other. Now there is no continuitie betweene the Vmbilicall Veine and the Hollow Veine, vnlesse it be by the inoculations of the roots of the Gate Veine. What is more absurd then to thinke, first that the *Parenchyma* of the Liuer is made of the Vmbilicall Veine, & afterward that from that *Parenchyma* the roots of all the Veines should arise? Are not the Spermaticall parts delineated before the Fleishy? On the other side, who will say that all the Arteries are propagated from the Vmbilicall Arteries, seeing they reach not directly to the Heart but to the *Iliacke* branches? Would we commend the Builder who would set vp his Walls before he lay his Foundation? I know what will be said, that these Vessels are the roots by which the Infant is nourished after the manner of a Plant, now the roots are first formed. But they must know, that the Infant is not nourished before his Spermaticall parts be delineated, because before that time there is no necessitie of nutrition.

We resolve therefore, that these Vessels are begun together with the rest of the Spermaticall parts, and that the Vmbilicall Veine is a branch of the Gate Veine to which it is continued; that the two Vmbilicall Arteries are Scions or Shoots of the *Iliacke* branches of the descending Trunke of the great Arterie; finally, that the *Vrachos* ariseth from the bottome of the Bladder and ascendeth vnto the *Nauill*. Yet we thinke that the Vmbilicall Veine and Arteries are perfected before the rest of the Vessels, because there was more need of them for the coagmentation or gathering of the Fleish, especially of the Bowels.

QUEST. XIX.

Of the times of the Conformation of a Man and of a Woman-child.

WHich is the first and which is the last day of the Conformation of the Infant, God alone knoweth who made them; and if we haue any thing to say of this matter, we haue it out of *Hippocrates* Fountaines. His opinion is (in his Booke *De Natura Pueri*

Pueri and De Principijs) That the seventh day the rudiments of all the Spermatick parts doe appear, but the perfect dearticulation and description of the Female is in 42 dayes, and of the Male in 30 at the longest. But this we thinke is to be vnderstood onely of the first Conformation; for we doe not belieue that the Flesh of the Muscles is in that space perfected and accomplished, but the third or the fourth month rather, at what time the Infant beginneth to mooue: so that we make a double Conformation, one of the Seed another of the Blood; the first goeth before, which therefore *Hippocrates* in his Booke *De Septimestri Partu* and *De Natura Pueri* calleth *σπέρματος* *σύνθεσις*, the first coagulation or coagmentation; the second doth onely fill vp the distances of the first, that is, the spaces betwene the Threds and the Fibres.

The time of conformation

A double conformation.

Strabo the *Peripateticke* and *Diocles Carystius* dispense the fabricke of the Infant by seuens and seuens, alluding to that maiestie of the Septenarie number which *Plato* conceineth it to carrie in it. Others thinke that 45 dayes is the utmost limit of Conformation. For sixe dayes they ascribe *Spumificationi*, to the frothing of it; foure *Lineationi*, to the delineation; eight to the Repletion of the Lines; fourteene *Carnificationi*, to the generation of Flesh; finally, thirteene *Afformationi*, to the accomplishment. The least time of this processe of Nature is thirte dayes, sixe for Spumification, two for Delineation, foure for Repletion or filling of the Lines, nine for Carnification, and as many for Afformation.

Strabo and *Diocles*.

Others thus in Verse:

Sex sunt in lacte dies, ter sunt in sanguine terni.

Sis seni Carnem, ter seni Membra figurant.

Sixe dayes it is in Milke, in Blood three thrice accounted;

Twelue figure the Flesh, Members sixe thrice amounte.

Hippocrates much more diuinely and distinctly: *Males are formed at the uttermost the 30 day, and Females the 40 or the 42.* Now the reason why a Man-child is sooner formed in the Wombe then a Woman, and yet a Woman out of the Wombe sooner commeth to perfection then a Man, is indeed worth the search. This *Hippocrates* hath left vs in the second Section of his sixth Booke *Epidemion*: *Mas concreuit coaluitq. citius, ubi motus est conquiescit & tardius augetur longioreq. tempore.* A Male gathereth sooner and is sooner articulated, after he moueth he stineth his motion and groweth more slowly and in a longer time. The same also he hath in the third Section of the third Booke *Epidemion*: *That which moueth sooner and is sooner articulated is longer encreasing in his growth.* The demonstration of the truth of this is to be fetched also from *Hippocrates*: *The Man-child is sooner formed in the Wombe because he is hotter, for Conformation is the worke of heat.* And in the first Booke *De Diata*: *Males are generated of hotter Seed, Females of colder.* And in his Booke *De Natura Pueri* in expresse words: *This is the reason why a Female is formed and articulated later then a Male, because the Seed of the one is moyster and weaker then the Seed of the other.* Add hereto the nature and condition of the place, for Males for the most part are generated in the right side, Females in the left, as appeareth in the 48 Aphorisme of the first Section: *Now the right side is hotter then the left.*

Hippocrates. Why the Male is sooner formed in the Wombe.

But why the Female out of the Wombe is sooner perfected, we must seeke for a demonstration out of *Aristotle* in his Booke *De Ortu & Interitu*. *The times of perfection and imperfection ought to be proportionably answerable one to another; corruption is an imperfection, but accretion and generation are accounted kinds of perfection; what soeuer sooner perisheth attaineth also sooner his perfection.* So an acute and short disease runneth suddainly through all his foure times, and commeth sooner to his heighth or pitch then a chronicall or long disease. Now for the most part and generally Women dye sooner then Men, as being of a shorter life because the principles of their life are weaker, and therefore they also doe sooner attaine the perfection of their life. To this we may add the softnesse of their Bodyes which makes them more apt for extension.

Why the Female is sooner perfected out of the Wombe *Aristoteles* Reason.

Hippocrates who was ignorant of nothing, in his Booke *De Septimestri Partu*, expresseth this briefly and plainly in these words: *After Females are separated from their Mothers (that is, are borne) they cotten sooner then Men, grow sooner wise and sooner old; as well because of the weakenesse of their Bodyes as by reason of the manner of their life.* He therefore acknowledgeth a double cause; the first is weakenesse, so that that which in the Wombe was the cause of their slower conformation and motion, the same is the cause out of the Wombe of their more suddaine and accelerated perfection. For a Female is a thing more imperfect then a Male, and hath her end nearer then he, and therefore needeth not so long a worke of Nature. The other cause is the manner of their dyet and course of life; for their life is idly led in want of exercise. Now slothfulnesse, saith *Celsus*, dulbeth the Body, labour strengtheneth it;

A double Reason assigned by *Hippocrates*.

Celsus the

Hippocrates.

NOT ANNOT.

the first maturateth or hasteneth old-age, the second prolongeth youth. Neither, saith Hippocrates in his Booke *De Victus ratione in Morbis Acutis*, can a Man enjoy perfect health unless he labour his Body and take paines. And in the fourth Section of the sixth Booke *Epidemion*. The best way to maintaine health, is to eat vnder facietie and to be free and diligent at labour.

of the
Individuum

AS among Philosophers there is a three-fold forme of euerie Creature: the first specificall; the second of the Sexe; and the third of the *Individuum* or particular by which it is that and no other thing: So among Physitians there is a three-fold similitude: the first in *specie*, i. in the kind; the second in the Sex; the third in the fashion or feature or indiuiduall figure.

The similitude of the kind they call that, when a Creature of the same kind is procreated as a Man of a Man, a Dogge of a Dogge: for euerie thing worketh not vpon euerie thing, neither doth euerie thing suffer by euerie thing; but euerie Agent worketh vpon his determinate Patient; and therefore of the Seed and Blood of a Man onely a Man is made. In this specificall similitude there is much attributed to the materiall cause, and that is the reason why the Of-spring is vniuersally liker to the Female then to the Male, for the Female affordeth more matter to the generation then the Male: so of a she Goat and a Ram is generated a Kid not a Lambe, of a Sheepe and a he Goat a Lambe not a Kid.

The similitude of the Sex (that is why a Male or Female is generated) hath for cause the Temper of the Seed, his mixture and victorie. For if the Seed of both Parents be hot Males are generated, if cold Females. If in the permixtion of the Seeds the Male Seed haue the vpper hand a Male is procreated, if the Female Seed a Female. This first of all Hippocrates taught in his first Booke *De Dieta*, where he acknowledgeth in either Sex a double Seed, the one Masculine hotter and stronger, the other Feminine that is colder, out of the diuers permixtion of which, both Males and Females are generated.

He therefore thus distinguisheth a three-fold generation of Males and Females. If both the Parents yeeld a Masculine Seed they breed Male Children of a noble and generous disposition, *καὶ τὸ σῶμα ἰσχυρὸν*, Nobly minded & strong of Body. If from the Man there issue Masculine Seed from the Woman Feminine and the Masculine preuaile a Male will be generated, but lesse generous & strong then the former. If from the Woman there issue Masculine Seed, from the Man Feminine and the Masculine ouercome a Male will be generated, but womanish, soft, base and effeminate. The verie like may be said of the generation of Females: for if from both the Parents doe issue Feminine Seed a Female will be procreated most weake and womanish: Which Hippocrates in the first Section of his sixth Booke *Epidemion* calleth *ὑδαρινὸς*, *Aquefcentes*, soft, waterish & loose Bodyes. If from the Woman proceed a Feminine Seed and from the Man a Masculine and yet the Feminine ouercome, Women are begotten bold and moderate. If from the Man proceed Feminine Seed and from the Woman Masculine, and the Womans Seed preuaile, Women are begotten *τολμηροτερὰ καὶ ἀνδρείαι*, that is fierce and mannish. The Temper therefore of the Seed and the victorie in the permixtion are the causes of the similitude of the Sex, that is of Males and Females; which causes are also not a little assisted by the Temper of the Wombe and the condition of the place, for as I haue often said, Male Children are borne in the right side, Females in the left.

The third similitude remaineth, which consisteth altogether in the Figure, Forme and Accidents of the *Individuum*. This Galen in his second Booke *De Semine*, will haue to consist in the differences of the parts & in the conformation of the Members. By this, one is white another blacke, one hawke-nosed another flat or saddle-nosed. In this similitude of the *Individuum* consisteth all the difficultie of this Question, which we will mince as small as we can that it may be digested without labour, from hence taking our beginning.

The Infant sometimes is altogether like the Mother, sometimes altogether like the Father, orher sometimes like them both, that is, in some parts resembling the Mother, in others the Father. Oftentimes he resembleth neither the Father nor the Mother, but the Grandfather or the great Grandfather, sometimes he will be like an vnknowne friend, as for example,

ample, an *Aethiopian* or such like who neuer had hand in his generation. Of all these similitudes we haue many examples in Authors of approoued credite.

The People called *Cannata* haue common Wiues, and euerie Man chuseth his Children or refuseth them as they are more or lesse like vnto himselfe. Among the *Chimians* the Children are like their Fathers in their Nose, their Eyes, their Forehead and their Beard. There haue beene in certaine Stockes and Tribes signes which they called *Signa Gentilitia*, that is, Stocke-markes, as to the *Spartanes* and *Thebanes* a Launce, some had a Starre, *Thyestes* a Crabbe, which were imprinted in their Bodies from their birth; and these sometimes were extinguished in their Children and Grandchildren, but after a long time appeared againe in their Posterities.

Selucus and his Posteritie had in their Thighes the fashion and representation of an Anchor. *Julia* the Daughter of *Augustus Caesar*, although she playd false and had many Copesmates, yet all her Children were like her Husband. Being asked what Art she had for that conueyance, she answered wittily and in some sort honestly in respect of others of her profession: *That she neuer tooke in her passengers till her Ship were full fraughted.* I passe by what might be said of the *Lensuli* and the *Macrocephali*: It will concerne vs more to spend our time in the search after the causes of these things.

The cause of this similitude or likenesse of the Forme and feature is verie obscure and full of Controuersie. *Empedocles* the *Pythagorean* referreth the cause of this likenesse onely to the Imagination, whose force is so great, that as it oftentimes changeth the Body of the Imaginer, so also it transferreth his efficacie into the Seed conceived. The *Arabians* attributed so much to Imagination, that they thought the Soule might so farre be eleuated by Imagination, that it should not onely worke vpon it owne Body, but also vpon an others: and that Soules so eleuated and enobled were able to change the Elements, to heale diseases, to weaken whom they listed, to worke myracles, and finally to exercise a kind of command ouer all kinds of matter. *Aristotle* in the twelfth Probleme of his tenth Section, acknowledgeth this power of the Imagination in the Conception and Infant conceived. For he asketh the question why the off-spring of Men are so vnlike one to another: and maketh answer, because in Man the swiftnesse of the cogitation and the varietie of their wits did imprint many and diuers markes and seuerall Impressions.

Galen in his Booke *De Theriaca ad Pisonem*. I counselled (saith he) an *Aethiopian* that he might beget a white and beautifull Child, to set at his Beds-feet a faire Picture, vpon which his Wife might wisely looke in the time of her conception. He obeyed my counsell and obtained his desire. And that was the reason why *Hesiodus* forbade Women to haue companie with their Husbands when they returned from a funerall, but when they came from bankets and disports. For the illustration of this we haue a Storie of a Sabine wife, of whom *S. Thomas More* wrote an elegant verse. And *S. Hierome* in his Questions vpon *Genesis* maketh mention of a Woman who was suspected for an Adultresse because she brought forth a Child no way like her Husband, but cleared her honestie because she shewed a Picture in her Chamber like the Child she brought forth. Thus *Iacob* in the 30 of *Genesis* cunningly made the greatest part of the Flocke of a spotted Fleece, by laying before the Ewes spotted Rods. *Pliny* in the seventh Booke of his Naturall Historie remembreth many examples to this purpose, and *Fernelius* in the seventh Booke of his *Physiologia* conceiueth, that the Imagination onely is the cause of this similitude of the feature, by which alone he thinketh the Facultie which formeth the Figure is led and gouerned.

But me thinkes it is verie hard to make the Imagination the onely cause of this similitude. For, neither the Imagination nor any other Facultie which hath knowledge ioyned thereto is able to worke vnlesse it haue his obiekt present by which it may be mooued. Now we know that a Child often resemblenth one whom the Mother neuer knew. Add hereto, that in the coition all the Animall Faculties are almost intercepted, so as the Forming Facultie can scarce receiue or conceiue those Imaginations.

Againe, if the Imagination alone were the cause of the similitude then no Infant should be deformed, neither should they be troubled with hereditarie diseases: for no Mother wisheth or imagineth euill to her owne Children. The Astrologians referre the cause of the similitude to the Starres. For (say they) as often as the Sunne is in the Center of the Horoscope and the Conception is in the day time, so often are Sonnes begotten like their Fathers: And Daughters like their Mothers when the Moone is with the Center of the Horoscope if the Conception be by night, or when *Venus* is with

What our re-
solution is

What the formative faculty can do,

the Center of the Horoscope if the Conception be by day. But these are meere vanities.

There are others who referre the cause of this likeness onely to the motion of the Seed, and to the Formative Facultie. And this is *Aristoteles* opinion in his fourth Booke *De Generatione Animalium*, and *Galen* in his second Booke *De Semine*.

Aristotles Philosophy concerning this point is indeed verie wittie and excellent, but withall verie obscure. For he saith, that there are in the Seed many Motions; some are Actuell, some Potentiall. The Actuell motions are either Vniuerfall or Particular: Vniuerfall, which generate a Creature or a Man; Particular, which generate Males, and those such, that is, of such a Forme, Magnitude of Members, Lineaments and Habite. Those Motions which are Potentially in the Seed doe proceed from the Grandfather, great Grandfather and the Mother. If one of these Motions, to wit, that which is nearest and most particular be intercepted, then is transiſion made into the next motion, and if that be deficient, transiſion is made into the contrarie, and at length into the Vniuerfall. These distinctions of Motions which I doubt not seeme vnto you confused and intangled we will make more manifest by an example. In the Seed of *Socrates*, there is a power to beget a Male child like vnto himselfe: the Seed therefore is moued toward the forme of *Socrates*. This Motion, if it be hindred either by the Seed of his Wife which haply is stronger then his, or by the coldnesse of the Wombe, or by any other cause: then is that first motion of the Father dissolued and lost which was actually in *Socrates*, and transiſion is made into the motion of the Grandfather or great Grandfather which was not in the Seed of *Socrates* Actually but Potentially, and so the Child becommeth like *Socrates* Father or his Grandfather: if this second motion be interrupted then is transiſion made into a contrarie motion, that is, into the motion of the Seed of the Mother, which *Aristotle* calleth Contrarie, because Nature at the first hand and of her selfe euer intendeth the generation of a Male. Wherefore, in the stead of a Male shall then a Female be procreated like vnto the Mother, or the grandmother or the great Grandmother, whose *Effigies* or representation the Seed of the Woman potentially containeth. This third motion if it be intercepted, finally there is transiſion into an vniuerfall motion, and a Man shall be borne indeed, but like neither Father nor Mother.

Galen in his second Booke *De Semine* doth not acknowledge these so diuers motions of the Seed, but referreth the causes of the similitude to the temper of the Seed, and the diuers permixtions thereof, as also to the strength of the Formative Facultie. That learned Man *Erastus* referreth the cause of this indiuiduall similitude onely to the Formative Facultie, quire excluding the power of the Imagination, because he perceiued that blind Creatures brought forth young like vnto their Sires. *The Formative Facultie* (saith he) *hath no need of a Patterne: For as in the Seed of Lettuce that Facultie being therein, generateth and formeth a Lettuce without a Patterne: So in the Seed of a Man, the Formative Facultie accomplisheth his worke without any Patterne or Imagination at all.* But what will *Erastus* say to that white Woman who attentiuely fixing her eyes vpon the Picture of an *Aethiopian* brought forth a blacke Child? What to her that brought forth a hairie Child by looking often vpon the Picture of *S^t Iohn Baptist* cloathed in Cammels haire?

We, that through the waues of this turbulent Sea of opinions we may ariue in a safe Harbor, will acknowledge a double cause of this diuers similitude, which is in the Feature, Forme and Accidents of the *Individuum* or particular Creature. The one ordinarie which alwayes worketh vnlesse it be interrupted, and this is the Formative Facultie ingenite with the Seed: the other extraordinarie which doth not alwayes concurre to generation, but commeth from without and is more noble then the former, because it hath power ouer it now and then and setteth a new seale vpon the tender and soft nature of the Child, and this we call Imagination or Cogitation.

That first Forming Facultie because it containeth in it selfe the *Idea* of all the particular parts, if it worke freely and at libertie and be not interrupted by any thing in the whole time of the conformation as it hapneth in other Creatures and in Plants, it euermore setteth that stampe vpon the Infant which is in the Seed it selfe, and so the Children become alwayes like vnto their Parents; wholly to the Father if the Fathers Seed doe alwayes and totally ouercome; and altogether to the Mother if the Mothers Seed haue the victorie: In some parts to the Father, in others to the Mother if any part of the Seed of either be ouercome by the other. For though the Seed appeare to the view *Homogenic* yet hath it some parts more thicke others thinner.

Sometimes the Children represent the Grandfather or great Grandfather, because there lurkes yet in the Fathers Seed some facultie deriued from them. For *Aristotles* opinion is, that the *Species* or forme of the Parents may be extended to the fourth Generation: And euen as a Loadstone shooteth forth his force and efficacie through the Needles hanging one at the end of another to the fourth or beyond, so that Formatiue Facultie is transmitted from one Seed to another. So *Helis* who accompanied with an *Aethiopian* did not bring forth a black Daughter, but yet that Daughter of hers brought forth a blacke Sonne. And *Nicaus* the Poet of *Constantinople* though begotten of white Parents, did degenerate into the colour of his Grandfather who was an *Aethiopian*.

If therefore the Formatiue Facultie worke at libertie it will alwayes generate Children like the Parents; but if in the beginning of the conformation the Formatiue Facultie be hindred by another which is more powerfull and diuine then it selfe, such as is the Imagination, then will the Impression follow not the weaker but the stronger, and so the Infant will become vnlike the Parents. For the Imagination commandeth the Forming Facultie, because the Formatiue Facultie is but a production of the procreating power which is Naturall; but the Imagination is a principall Facultie: now what Imagination can doe as well in the conformation as after it we haue touched already, to which we will add these things to make vp the Question with.

Oftentimes the Imagination of that thing is imprinted in the tender Infant which the Mother with Child doth ardently desire, which is onely to be imputed to the strength of the Fancie. For the reall *Species* of a Figge or a Mulbery is not transported to the Wombe, but only the spirituall forme or abstracted notion, which is sooner fastned vpon the Infant then vpon the Womb, because an impression is sooner made in soft Wax then in hard Iron.

Furthermore, the manner of this impression *Auiscn* hath expressed in his first Booke *De Animalibus*, where he saith, That a strong Imagination doth instantly moue ayrie spirits which are mouable of their owne nature, and in these it setteth the stampe of the thing desired; the spirits being mingled with the Blood which is the immediate Aliment of the Infant, doe imprint in it the same Figure they receiued from the Imagination. But how the spirits should so suddenly receiue and apprehend the *Spectra* or Images represented by the Imagination, belongeth to a higher contemplation. Our opinion is, that as the Forming Facultie in the Heauens of those Creatures whose generation is equiuocall, is imprinted in the Aire; after the same manner the formes of the Imagination are insculped or engrauen in the Airie spirits. As therefore the Aire is full of formes (as we shall shew more at large when we come to the nature of the Sight) so our Spirits which are airie doe easily admit all *Species* or formes of things. So the Seed by reason of the Spirits which wander and gad vp and downe through all the parts of the Body doth containe in it selfe, as we haue shewed already, the *Idea* or Images of all the particular parts.

QUEST. XXI.

How Twins, or more Infants are generated.

THE Immortall God of his Diuine Prouidence hath giuen almost to all brute Creatures a power to bring forth many young at once lest their kinds should be extinguished, for that of themselves they are but short liued, and beside serue Man for food and rayment, yea prey also one vpon another. Man the most temperate and of longest continuance, by the prescript of Nature breedeth but one Infant at once, or at the most but two; because there is but one bosome in the Wombe of a Woman; but two parts thereof the right and the left distinguished onely by a line, not dissuered by any partition; and onely two Duggs appointed to nourish two Infants which we call Twins. And if at any time a Woman bring forth three or more, that seemeth to the Philosophers to be *para phisicis*, vnnaturall.

We haue many elegant Histories of such manifold burthens. In *Egypt* where *Nilus* that fruitfull Riuer runs, Women bring sometimes fixe at a birth. *Aristotle* in his seuenth Booke *De Historia Animalium* affirmeth that one Woman at foure birth brought into the World twentie all perfect. *Trogus* reporteth, that in *Egypt* it hath beene knowne that a Woman hath borne seuen Infants at once. *Albertus* telleth a Tale of a Woman in *Germany* who

be conceived

Three ques-
tions:

having 22 Infants formed in her Wombe suffered abortment, and of another who had at once 150, all of them being as bigge as a Mans little Finger. *Margaret Countesse of Holsteid*, is said to haue brought forth at one burthen 364 living Infants, who were all christned but dyed presently after: the Males were named *John*, and the Females *Elizabeth*. There remaineth to this day a Marble Sepulchre of hers in a Monasterie in *Holland*. There are also many other Histories of such-like burthens as these, which I willingly pretermitt, being more willing to spend my time in searching out the causes of them.

Many of the Ancients referre the cause of Twins and manifold burthens to the varietie of the bosomes of the Wombe, for they make seuen bosomes in the Wombe of a Woman, which they call *celae* or Cels: three in the right side of the Wombe appointed for Male children, and three in the left appointed for Females, the seuenth in the midst wherein Hermaphrodites are engendred: but these are idle conceits, next a kin to old Wiues tales. For in a Womans Wombe there is but one bosome, as there is but one cauitie in the Stomacke, which yet may be diuided into the right side and the left. These sides are disseuered by no partition, whatsoever *Auicenna*, *Galiabbas* and many other Anatomists doe auouch, as they are in Sheepe, but onely distinguished by a Line, which *Aristotle* calleth *Septa*, that is, *A middle Line*, which word he tooke out of *Hippocrates* in his *Coaca Praenotiones*. Moreouer that the varietie of Cels cannot be the cause of the multiplictie of the burthen, that among other things may be an argument, because sometime twentie young ones or more may at once be conceived, but no Man I thinke will say there are so many bosomes in the wombe; neither yet in other Creatures are there so many bosomes as there are young, as appeareth in Fishes who haue an infinite number of Spawne, yet no partition or distinction betweene them. *Erasistratus* referreth the cause of Twins to a repetition of conception. *Empedocles* vnto the plentie of Seed: *Ptolomy* to the diuers position of the Starres. The true cause *Hippocrates* acknowledgeth in his first Booke *De Dieta*, to be the diuision of the Seed. So it was necessarie that the Seed be diuided equally into both sides of the Wombe. For oftentimes in coition, all the Seed is not at once eiaculated but by fits or turnes; so saith our Master: neither doth the Seed alwaies issue at once, but it boyleth & is eiaculated at twice or thrice. A part therefore of the Seed falleth into one side of the Wombe, and another part into another, and so Twins are conceived.

Asclepiades referreth the cause of Twins to the excellencie of the Seed, which if it be strong is able to make many Infants. *Auicenn* addeth as another cause, the motion of the Wombe, which draweth vnto it selfe the Seed of a Man & disposeth it diuersly, bestowing the parts of the Seed in this side and that side of the Wombe from whence comes a multiplicitie of Conceptions. And these are all the causes of Twins or many Infants. But that their Conception and Conformation may the better be manifest, we are to discusse three Questions. The first, whether at the same coition a Male and a Female may be procreated. Secondly, whether Twins are included within the same Membranes, and contained in diuers places. Lastly, why Twins are commonly so like one another: and all these we will resolue out of *Hippocrates*. For the first, we say that at once two Males, two Females, a Male and a Female may be conceived at one and the same coition. The manner is thus expressed by *Hippocrates* in his first Booke *De Dieta*, and in his Booke *De Natura Pueri*: If from both Parents Masculine Seed doe issue, then are two Males generated; if Feminine Seed, two Females; if both Masculine and Feminine, then of the Masculine is a Male conceived, and a Female of the Feminine. Moreouer, Twins that are both Males or both Females doe for the most part suruiue, but if they proue a Male and a Female, the Female doth scarce suruiue, or at the least is verie weake, because it is not formed and perfected at the same time wherein the Male is formed and perfected. This *Aristotle* expresseth verie plainly in the sixth Chapter of his fourth Booke *De Generatione Animalium*: If the Twins be a Male and a Female they rarely suruiue, because this duplication in Men is vnnaturall, for that the Male and the Female are not distinguished in the same time, vnlesse the Males conformation be fore-slowed, or the Females ouer-hastned.

The second Question *Hippocrates* answereth in his Booke *De Superfætatione*: The Woman, saith he, that is with Child with Twins, trauelleth of them both in one day, and if they be both of one Sex they are contained in one after-birth. Wherefore the Twins of the same Sex are wrapped in the same Membranes, yet each of them haue their particular Umbilicall Vessels: but if they be of diuers Sexes they haue their diuers Coats. Again, if they be both of one Sex they are carried in the same side of the Wombe, two Boyes in the

the right side, and two Wenchies in the left; but if they be of different Sexes, the Male shall be concluded in the right side of the Wombe, and the Female in the left.

The third Question was, why Twins are so verie like one another. *Hippocrates* in his first Booke *De Diata*, acknowledgeth a three-fold cause of this similitude. First of all, saith he, the places wherein they receiue their augmentation are equall, whether they be conceived in the right or in the left side of the Wombe, because by a wonderfull prouidence of Nature, the right are equall to the left, that so the whole Body might be *ισογενετον*, that is, equally ballanced; againe because they are conceived together; lastly because they vse the same Aliments, for they sucke the same Blood and enioy the same Vitall Spirits which they draw from their Mother by the Vmbilicall Arteries. And thus much of Twins, now we proceed to *Superfætation*.

QUEST. XXII.

How Superfoetation is made, why onely a woman when she hath conceived desireth the companie of the Male, and by what wayes she then eiaculateth Seed.

Here are so many difficulties concerning the nature and manner of *Superfætation* that many Men haue imagined there can be no such thing, but we must not giue care vnto them. For *Hippocrates* wrot a Booke *De Superfætatione*, and there is a notable example of *Superfætation* in his first Booke *Epidemia*: In a Woman of *Larissa*, who the fortieth day after her deliuerance of a legitimate Child auoyded another preposterously conceived. Famous also is that birth of *Alcmena*, when she brought forth *Hercules* and *Iphiclus* his Brother after him. *Aristotle* in the fifth Chapter of the fourth Booke *De Generatione Animalium* saith, that some Creatures admit *Superfætation*, others doe not admit it: and of these that doe, some are able to nourish both burthens, some are not able sometimes, at other times they are able. And in his Booke *De Historia Animalium*, he alleageth some examples of *Superfætation*: A certaine Adulteresse, saith he, brought forth one Infant like her Husband, another like the Adulterer. Another being with Child with Twins had a third by *Superfætation*. Another brought forth one the seuenth month which dyed, and in the ninth was deliuered of two others which did suruiue. *Galen* makes mention of *Superfætation* but seldome. *Rhazis* 22, *Continent*, *Alzaranius* and *Auicenna* are all of opinion, that those Women are subiect to *Superfætation* who whilst they are with Child haue their Courtes. *Pliny* in the eleuenth Chapter of his seuenth Booke writeth, That *Procennia* a Seruant-Maid accompanied the same day with her Master and his Man, and conceived by them both, and bare either of them a Sonne like to the Father. That another was deliuered of a Child at five months and went out her iust time with a second. That another was deliuered of a Child at seuen months and went out her whole time with two Twins beside. *Dodoneus* in his Obseruations, telleth Stories to the same purpose. We conclude therefore, that there may be *Superfætation*. Now this *Superfætation* is nothing else but a second Conception, when a Woman already with Child accompanying with a Man conceiue againe, as if it were a new Conception aboue another before conceived. This *Superfætation* or iterated Conception is not common to all Creatures, as *Aristotle* teacheth in his fourth Booke *De Generatione Animalium*: To Women it hapneth oftner then to other Creatures, vnlesse it be Hares and Swine; notwithstanding whensoever it hapneth, it is beside the ordinarie course of Nature.

Now the reason why *Superfætation* hapneth most in Women, is because Women (and they almost onely) after their Conception doe desire the companie of their Husbands. Other Creatures when they are pagled, as we say, doe neuer or verie seldome admit the Male: but what may be the reason hereof? *Dionysius* in his Commentaries vpon *Hippocrates* Booke *De Natura Pueri* saith, That other Creatures after they haue conceived, doe not desire the companie of the Male, because all that which should be the matter of new Seed is consumed in the nourishment of their young, and therefore they are not goaded with their wonted lust. But a Woman, because she hath in her abundance of moysture, hath also her Vessels full of Seed, from whence comes the motion and sence of the obscene parts. But this reason I cannot approue. For although the Infant doe consume almost all the reliques or surpluse of the Blood, yet doth it not defraud the parts of the Mothers Body

of their conuenient nourishment; neither taketh from the Testicles their proper facultie of drawing and altering the Blood. So Women at 60 yeeres old haue no surplufage of Blood and therefore their Courfes faile; yet they continue to procreate Seed euen to their extreme age, which also in coition they auoid, which though at that age it be not fit for generation, yet it is sufficient to prouoke pleasure.

Two passages
of Seed.

We acknowledge other causes of this disposition of Women and those naturall. For the Morall causes of which *Lactant.* writeth in his Book *De Vero Cultu* we leaue to Diuines. The first is, the scituation and conformation of the Wombe: for in other Creatures when they are great with young the Wombe is nearer the outward parts, and therefore more in danger to be violated by the Male whose Genitals are of a great length, and for the most part of a harder substance. But a Womans wombe is scituated further inward and beyond the Mans reach and therefore she beareth him the more easilier. Againe, to Beasts the vse of *Venus* is onely giuen for the preseruacion of their kind; if therefore they conceiue, the finall cause being satisfied their desire of coition is also appeased: but Man vseth these pleasures not onely to propagate his kind, but also to sweeten and mittigate the tedious and irksome labours and cares of his life. *Poppea* the Daughter of *Agrippa* being asked this question, *why Beasts did not copulate after they had conceived?* Her answer was, *Because they were Beasts.* And truly the answer beside the quicknesse of it was not amisse; for it is a prerogative which Nature hath giuen to Man aboue other Creatures. But to returne to our Question. It appeareth therefore that the reason why *Superfatiation* is more ordinarie in Women then in all other Creatures, is, because when she hath conceived yet she may desire the societie of the Male. Now let vs enquire how this *Superfatiation* may be.

Most certaine it is that the Wombe is so greedy of Seed, that after Conception it is so contracted that there is no void space left in it, and the inward Orifice so close shut that nothing can passe into it or issue out of it. This *Galen* teacheth vs in many places, and *Hippocrates* in the 51 Aphorisme of the fifth Section: *Those that are with Child haue the mouth of their wombes closed.* How therefore can it be that the Seed of the Male can arriue into the bosome of the Wombe to make a second Conception? There haue beene some of the Ancients who dreamt that by a wonderfull prouidence of Nature, the Wombe at certaine times did open it selfe to auoid those things which might otherwise offend it; at which times if a Woman with Child should accompanie with a Man, the Wombe might entertaine his Seed, and so breed a *Superfatiation*. But I take these to be but idle and addle imaginations: For if through the whole courle of those nine months the Wombe should at certaine times open it selfe to expell that that is superuacuous; why then are the *Lochia* (i. those Purgations which issue after Trauel) retained all the time in the wombe? or can the wombe at the same time that it auoideth that wherewith it is offended, receiue also the Seed whereby it is pleased and conceiue the same? Rather the Seed would so be extinguished.

Among the late Writers there are some who thinke that the Wombe is neuer so exquisitely shut, but that it may admit Seed; which their opinion they establish by these reasons. When Women are with Child they often auoid their Courfes Pallid, Flegmaticke or Blacke, which out of question lay lurking in the cauitie of the Wombe, and therefore the Orifice thereof is not so perfectly shut.

Againe, a Woman with Child in coition looseth Seed, which she perceiueth to issue from her by her lap, which way it could not issue vnlesse it came thorow the necke from the cauitie of the Wombe, because a Woman eiaculareth her Seed by the sides into the bottome of her Wombe. The Orifice therefore of the Wombe is alwayes open and so hapneth *Superfatiation* the more easily. With these arguments they thinke they haue won the cause, whereas for want of skill in Anatomie they cast a mist ouer *Hippocrates* Sun-shine. For that I may answer their first argument. It is manifest by this manner of reasoning that they are ignorant, that there are two Veines which disperse their branches through the Wombe, some of which are carried to the inward cauitie thereof by which the Infant is nourished, others run to the outward part of the Wombe euen vnto the necke and the lap it selfe. By these all the time of their ingrauidation or in which they goe with Child, the Blood issueth and the superfluties of the Body are purged without interruption, although the inward Orifice of the Wombe be neuer so closely shut. Their latter reason would vrge more but that we find two passages whereby the Womans Seed is auoyded. The first passage determineth in the hornes or sides of the Wombe by which the Seed is eiacularated into the bosome of the wombe when a woman is not with child, for it is the shorter & the opener way.

The

The other passage was vnkknown to the Ancients and to many also of the later Anatomists, but easie to be obserued in Dissection if it be diligently sought for. It ioyneth with the former but is longer, and runneth along the sides of the Wombe and the necke and endeth in the lap. By this passage we belieue that Women with Child doe auoid their Seed, and therefore doe conceiue greater pleasure in their Husbands companies, because the Seed runneth a longer course through the Vessels and beside through the Membranous necke of the Wombe, both which are of exquisite fence.

The manner of *Superfetation*, Hippocrates first of all opened in his Booke *De Superfetatione*, where he saith: *Superfetation hapneth to those Women, the mouth of whose wombe after their first Conception is not close shut.* For if at that time a Woman doe againe accompany with her Husband, she will easily receiue his Seed and lay it vp in the bosome of the Wombe, from whence commeth a second Conception. Now this must be vnderstood of the third or fourth day after the first Conception, for the Wombe cannot abide open all the time of Conformation.

But a Question may be asked whether *Superfetation* may happen after the first, second or third month of the first Conception, as many Men doe write and alleage many examples therefore?

We answer, we thinke it may so happen but very rarely: for the Wombe may be so enraged, that it may open againe and receiue new Seed, and yet the former conception not be violated if the Woman be sound and the Infant strong, as well because it is firmly tyed to the wombe, by the mouth of the vessels, as also because as yet it seeketh not to be enlarged.

This we (saith *Laurentius*) haue sometimes obserued in Twins. *I saw (saith he) a noble Woman conceiued of two Twins, who first was deliuered the first day of the ninth month of a dead Child, and the seuenth day after of another aliue.*

The like Historie there is in Hippocrates seuenth Booke of his *Epidemia*, whose words are these: *Terpida a woman of Doriscus (a Citie of Thracia) when she had gone with Twins siue months, by some mischance suffered Abortment, the one issued forth presently compassed with a Membrane, the other she went with about fourtie daies after.* The inward Orifice of the Wombe may therefore be opened, and yet the Infant remaineth behind. We haue also for this the authoritie of Hippocrates in the 38 Aphorisme of the fifth Section, where he saith: *A Woman with child with Twins, if either Pap fall and grow loose, she will abort of one of her Children: if it be the right Breast, of a Male, if it be the left Breast, of a Female.* The Infant therefore may be retained in the Wombe although the Orifice of the Wombe open euen to an Abortment. And although the second Conception happen the third or the fourth month, yet it is not necessarie that the first should miscarrie; and yet the second Conceptions doe seldome thriue and suruiue, especially if they be long after the first, because the former Infant being great draweth away most part of the Blood, whence it commeth to passe that the younger Brother is defrauded of his nourishment, and so perisheth and is most what auoyded before his due time. And so much of *Superfetation*. Now it is time that we proceed vnto the Controuersies concerning the nourishment and augmentation of the Infant.

QUEST. XXIII.

Whether the Infant draw his nourishment at his Mouth.

OV R whole Disputation concerning the nourishment of the Infant we will absolute in three Questions. In the first we will dispute by what wayes he draweth his Aliment. In the second, what kind of nourishment he draweth. In the third, how that nourishment is changed and whether it passe all three concoctions.

For the first, *Alcmaeon* thought that the Infant drew his nourishment by his whole Body, because it is rare and spongy; and as a Sponge sucketh vp Water on euerie side, so thought he the Infant sucketh Blood not only from his Mothers veines, but also from the substance of her Wombe. *Democritus* and *Epicurus* thought, as *Plutarke* reporteth in his fifth Booke *De Placitis Philosophorum*, that the Infant in the wombe drew his nourishment at his mouth, which thing also Hippocrates seemeth to confesse in his Booke *De Principijs*: *The Child in the Wombe gathering his lips together, sucketh out of his Mothers Wombe and draweth both Aliment and Spirit to his Heart when the Mother breatheth.*

The manner of Superfetation out of Hippocrates.

Whether Superfetation may be after two or three months.

Histories

Terpida

Hippocrates authoritie.

Second conceptions rarely thriue.

Which way the Infant drawes nourishment.

Alcmaeon opinion

Democritus and Epicurus

Hippocrates corrupted.

Hippocrates
excused,

His owne
opinion
in many places

This opinion he confirmeth with a double reason. First, because Children when they are borne haue Excrements in their Guts. Secondly, because as soone as they are borne they sucke Milke with their Mouthes, because they were accustomed to sucke in the womb. *Hippocrates* verily was so diuine a writer, that in all that he saith we are bound to reuerence him and giue good heed vnto him. And therefore herein we are either to excuse him, because in those times the skill of Anatomy was but in the infancie; or else we may thinke that this, as many other things, was foysted into his worke. For, in his golden Booke *De Nutritione*, he maketh knowne vnto vs the wayes of this nourishment of the Infant in this Oracle: *The first Aliment is through the Abdomen by the Nauell*. As if he should say: the first Aliment is drawne by the Nauell, because it is scituated in the midst of the *Abdomen*. For how should he draw it by his Mouth seeing there are no Vessels deriued thither? Neither hath the Infant any coniunction with the Wombe of the Mother vnlesse it be by the mouthes of their Vessels meeting together, all which Vessels do determine into the Nauell. Moreouer in his Booke *De Natura Pueri* he writeth in plaine words, that the Infant draweth both his nourishment and his spirit or breath by the Nauell. *In the middle of the Flesh is the Nauell separated, by which the Infant breatheth and getteth his encrease*. And in his Booke *De Oetimestri Partu*, *The Nauell by which the way is for the Aire and the Aliment to sustaine the Infant, and the onely ingresse by which he cleaueth to his Mother. And by this way is the Infant made partaker of those things that enter into the Body*. And againe in his Booke *De Natura Pueri*, *The Midwife as soone as the Infant is borne tyeth his Nauell, as being no more necessarie to nourish him by; and withall she openeth his Mouth to shew him another way by which he should receiue his nourishment*.

Why the In-
fant sucketh as
soone as he is
borne,

Scaliger.

What it is the
Infant auoy-
deth downe-
ward.

Seeing therefore *Hippocrates* in all these places teacheth vs that the Infant draweth his nourishment and aire also by the Nauell not by the Mouth; we conclude that the place about vrged is surreptitious. For the reasons which he is made in that place to giue are not befeeming the learning of so great a Man, neither answerable as you see to his opinion in other Tractates which are legitimate and past exception, as which indeed none but the diuine wit of *Hippocrates* could endite. Neither therefore doth the Infant sucke Milke after he is borne because he was accustomed to sucke in the Wombe, but because he is so taught by vntaught Nature. The same hath *Hippocrates* in the sixth Booke of his *Epidemia: Nature not taught doth yet that rightly which she hath not learned*. And in his Booke *De Nutritione*, *Nature is taught of none*. The Infant therefore instantly sucketh, not from Custome but by Nature or by Will, which is by Instinct: for after he is growne old he will sucke againe if he thinke it fit so to doe: because, as that most subtle *Scaliger* saith in his 239 Exercise: *There is but one Facultie which serueth the Soule for the behoofe of the Body, which also hath therewithall adioyned a notion of his owne conseruation*.

As for those Excrements which the Infant auoydeth by sledge as soone as it is borne, they are not Excrements of the first Concoction or of Chylification, and therefore cannot properly be called *Feces* and *Stercora*; but Recrements of the more impure and thicker Blood, which are conuaid by the Spleenicke and Mesenteriall branches from the Spleene to the Guts, and there by long stay and heat doe grow dry and exiccated. Wherefore we conclude that the Infant draweth not his nourishment by his Mouth but by the Nauell.

QUEST. XXIIII.

Whether the Infant be nourished onely by Blood, and whether he accomplish onely one Concoction.

That the In-
fant is nou-
rished with
pure Blood.

Concerning the nature and kind of Aliment wherewith the tender *Embryo* is nourished so long as he is contained within the Mothers Wombe, there is no light Controuersie. *Hippocrates* thought that he was nourished with the purest part of his Mothers Blood. To this purpose there is an elegant place in his first Booke *De Morbis Mulierum*. *A woman with child* (saith he) *is all ouer of a greenish pallid colour, because her pure Blood is daily drawne from her, and descendeth to the nourishment of the Infant*. *Galen* in his first Booke *De Causis Symptomatum* and the seuenth Chapter saith, *That the small and tender Infant drawes in the first monthes the purest of the Blood, but when he is growne greater, he draweth the pure and impure together*.

Hippocrates in his Booke *De Natura Pueri*, wrot many things but verie obscurely, concerning

ning the Aliment of the Infant: for he acknowledgeth a double Aliment, Blood and Milke. In the first months he thinkes the Infant is nourished with pure Blood: but *when he beginneth to moue, that then a part of the Blood returneth to the Paps, and is there turned into Milke, and from thence commeth againe to the Wombe by the communion of the Veines for the nourishment of the Infant*; as if the Blood were circularly conuaid from and to the Wombe againe as Chymists vse to doe in their Distillations. But I see not either why or how the Infant should be nourished with Milke, seeing all his Aliment is carryed first by the Veines vnto the Liuer: Vnlesse we shall say that the Infant growne great is nourished with Milke, that is, with Blood contained in the Veines of the Paps, which commeth neere to the nature of Milke. For when the Blood is exhasted or drawne out of the first Veines, he draweth Blood from other Veines, especially from such as are more common and ample or large. Now the societie of the Veines of the Wombe and the Paps is admirable. Here some Man may aske how the Infant can draw pure Blood seeing it hath much Whey mingled therewith, which is proued by the collection of the Vrine? I answer, that the naturall Whey doth not take away the puritie of the Blood, yea if it wanted his Whey it were not pure but altogether faultie: and Hippocrates alwayes disalloweth of that Blood which is *exempt*, that is, sincere and vnmixt.

Whether the Infant in the wombe be nourished with milke

Hippocrates expounded.

Obiection.

Solution.

The third thing to be enquired of remaineth, that is, how the Aliment of the Infant is changed and altered, whether it passe through the three concoctions, or but two, or onely one? Some imagine that the Blood is conuaid by the Vmbilicall Veine to the branches of the Gate Veine, from these vnto the Stomacke where it is conuerted into a substance like vnto Creame, and thence by the branches of the Mesenterie transported to the Liuer, and by it turned into Blood, and so is made by Chylification and Sanguification in the Infant. For Blood if it be taken at the Mouth and swallowed into the Stomacke, putteth off his forme of Blood, and acquireth a new forme of Creame. For my selfe if I may speake as I thinke, I conceiue that there is but one concoction in the Infant; for what need is there of Chylification or of a new Sanguification, seeing he draweth the purest of his Mothers Blood? I confesse that it is perfected and further boyled as well in the greater as in the lesser Vessels, that so there may be the greater similitude betweene the Infant and his nourishment; but that it should acquire a new forme, that will not sinke into my mind; for the Blood remaineth Blood and hath the same power of nourishing it had before, onely it differeth in perfection and in some accidents.

How many concoctions are in the Infant.

As for Chylification that was not necessarie in the Infant, because the Excrement of Chylification which is thicke and fœculent or euill sauoured would with the weight and burthen be troublesome to him, seeing he hath no Membranes allotted for the receiuing or containing them. Hereto you may also add the noysome smell of the Excrements, which doubtlesse would be offensive both to the Infant and to his Mother. We conclude therefore that in the Infant there is no other but onely the third concoction.

That there is onely the third concoction.

QUEST. XXV.

Of the communion of the foure Vessels of the Heart in the Infant.

The first Exercise.

Wherein the truth of Galens demonstration is illustrated.

HAT wonderfull communion of the Vessels of the Heart which is found in the Infant, to wit, of the hollow Veine with the Venall Arterie, and of the great Arterie with the Arteriall Veine, Galen first of all Men hath so excellently described in his sixth and fifteenth Bookes of the Vse of Parts, that there is nothing in that whole Worke more plainly, more clearely, nor more diuinely handled: But in the vse of these Anastomoses he hath not so sufficiently playned himselfe. For in the fifteenth Booke he thinketh that both those Inoculations were framed only for the Lungs sake; but in the sixth Booke he writeth that they are some helpe vnto the Heart for the performance of the offices of the Vitall Facultie. Wherefore because in diuers places he speaketh of diuers vses of them, although both places may well stand together, yet thence haue

Galen first described this communion.

But varieth in the vses thereof.

haue all those taken occasion to carpe at him, who either from a spirit of contradiction, or from an ambitious desire to gain-say great Men, or from a kind of wantonnesse of wit doe forsake the authenticke learning of the Auncients and seeke for a new kind of Philosophy in the Greene, raw and vnripe fruits of the later Writers.

How farre we
are to stick
to the ancients

It is not good indeed to pin a Mans knowledge vpon any particular Mans sleeue, neither doe I thinke it the part of a true Philosopher to swear that another Man hath said, were it *Hippocrates* himselfe: but yet wherein the Ancients haue gone before vs in strength of demonstration and euidence of truth, there to start aside after the nouell and vndigested inuentions of Greene wits, I hold it may be a signe of a ripe wit, but not of sound and established wisdome or iudgement. Wherefore I will endeavour in this place to shew you *Galen's* curious, elegant and accurate demonstration of the communion of these Vessels; afterward we will enquire also what other Men haue said of it.

Galen's elegant
demonstra-
tion of this
communion.

Galen therefore in his fifteenth Booke *De Vsu Partium* and the sixth Chapter, asketh the question, why the Lungs in the Infant are red and not whitish as they are after a Man is borne. He answereth, because they are nourished with thicke and red Blood brought vnto them by Vessels hauing but a single Coat, that is, by Veines. But there are no passages from the hollow Veine into the Lungs; and therefore it was of necessitie that that hollow Veine should haue a passage bored into the Venall Arterie. This therefore is the first and primarie vse of this hole or perforation.

Illustrated.

The vse of the other coniunction which is betweene the great Arterie and the Arteriall Veine by a Canale or Pipe running betweene them, he thinketh ought to be referred to the maintenance of the life of the Lungs. For all life is from the Vitall Spirit and the Arteriall Blood, that is deriued by the Riuerets of the Arterie; which because they no way pertaine or reach vnto the Lungs, it was of necessity that the great Arterie should be vnited to the Arteriall Veine. This is *Galen's* demonstration which haply will seeme to many obscure, but I will make it brighter then the mid-day Sunne.

The Lungs in the Infant are red, much like the Flesh or *Parenchyma* of the Liuer, and thicker beside then they are after a Man is borne; red they are, because they are both generated and nourished by red Blood; thicker, because they are neither attenuated by inspired aire, nor yet moued perpetually as they are after the birth. For we doe not thinke that the Chest of the Infant is moued in the Wombe; if the Chest be not moued then it is not likely that the Lungs are distended or contracted, because the Lungs are not moued by any proper or in-bred facultie of their owne, nor by the pulsatiue facultie of the Heart, nor by the Braine; but onely they follow the motion of the Chest to auoid vacuitie, as we shall hereafter more cleerely proue when we come in the next Booke vnto the Historie of the Chest. But when the Infant is borne the Lungs become suddenly more rare & spongy, and whiter by much because they are attenuated by perpetuall motion and by the permixtion of aire breathed into them.

Wherefore the substance of the Lungs is not the same in the Infant when he lyeth darkling in the corners of the Wombe and when he enioyeth the vse of the worlds light. If the substance be not the same, neither is it proportionable that the Aliment should be the same. The Lungs being rare and spongy stand in need of thin Blood laboured in the hot and boyling right Ventricle of the Heart, and therefore *Galen* thought that the right Ventricle was onely made for the vse of the Lungs. And as *Aristotle* first obserued those Creatures which haue no Lungs doe also want the right Ventricle of the Heart.

Now the thicke, red and immouable Lungs of the *Embryo* doe not need Blood attenuated, but are contented with that which is thicke and like themselves. This crasse and red Blood is onely conuained in the branches of the hollow Veine. But how should it attaine out of these branches of the hollow Veine vnto the Lungs, seeing there are no branches from that hollow Veine disperfed into the Lungs? for the Lungs haue only three Vessels. The Venall Arterie, the Arteriall Veine and the Rough Arterie. Here therefore Nature with wonderfull Prouidence & Art, perforated the Venall Arterie which adioyneth vpon the hollow Veine, therein to inoculate the Veine, that so the Blood might haue a free passage for the nourishment and encreasing of so fleshy a Bowell as the Lungs are; so that in the Infant the Venall Arterie performeth onely the office of a Veine, and may absolutely then be called a Veine as well for his vse as for his structure. This therefore is the true vse of that open hole, this the necessitie of that famous inoculation.

Anciens opini-
on of the vse
of this com-
munion.

Ancien the Prince of the *Arabians* hath confirmed this demonstration of *Galen*. The Lungs
(saith

(saith he) are red in the tender Infant, because he draweth no aire into them, for they grow not white but onely by the permixtion of breathed aire. They are therefore nourished with red Blood, and to that end is the hole made out of one Vessell into another, which is presently stopped after the Infant is borne.

Neither yet is this Inoculation made onely for the nourishment of the Lungs, but also for the first generation of their *Parenchyma* or Substance. For it is out of doubt that the Flesh of all the Bowels is made of the Blood congealed or clodded together. This Blood is onely brought by Veines, but there were no passages from the hollow Veine to the Lungs, and therefore there was bored an open and patent hole out of the hollow Veine into the Venall Arterie.

Second use
of it.

I will add a third use of this communion, that that Venall Arterie might be formed out of the hollow Veine. For a thin and Venall Vessell could not arise out of the thicke and crasse left Ventricle of the Heart: Now it was necessarie both that this Vessell should be fixed into the left Ventricle of the Heart and also be thin, that when we draw in our breath it might suddainly receiue the aire, and when we expire it might expell fumid and sootie vapors. It was necessarie therefore, that the hollow Veine should be vnited with the Venall Arterie; so that the Venall Arterie may seeme to be a production of the hollow Veine; and his first originall is not from the Heart as is commonly imagined, but from the Liuer by the continuation of the hollow Veine.

A third.

The use of the other communion which is betweene the great Arterie and the Arteriall Veine by the interposition of a Canale or Pipe, I thus manifest. The Lungs doe liue in the *Embryo*, therefore they stood in need of Vitall Spirits and Arteriall Blood for their conseruation. These Vitall Spirits and Blood are onely contained in the branches of the great Arterie; from this great Arterie into the Lungs there was at all no passage. Nature therefore (least the Lungs should be defrauded of that quickning *Nectar*) made an Arteriall pipe perforated from the great Arterie into the Arteriall Veine, by which a part of the Arteriall Blood and Vitall Spirits might be conuained vnto the substance of the Lungs.

These of the
other commu-
nion by the
Canale.

I acknowledge also another use of this second communion; that this Arteriall Veine might take his originall from the *Aorta* or great Arterie. For the Veine of the right side of the Heart stood in need to be Arteriall, that is, to haue a thicke Coat like that of the Arteries. Now the Fountaine of the Arteries was in the left Ventricle. Wherefore Nature propagated the great Arterie, and made out of it an Arteriall production or pipe which reacheth into the right Ventricle, there to forme the Arteriall Veine; so that hence it is euident that the Arteriall Veine is a production of the great Arterie, and the Venall Arterie a production of the hollow Veine. So it is therefore with the Vessels of the Lungs in an Infant yet contained in the Wombe, that the Venall Arterie performeth the office of a Veine, the Arteriall Veine of an Arterie, but the Rough Arterie is altogether idle. And this is the true demonstration of these two Vnions or Communions of the Vessels of the Heart in the Infant yet vnborne.

Another use
of it.

The use of the
Vessels of the
Lungs in the
Infant

The second Exercise.

Wherein the new demonstration of the use of these Communions divulged by
Simon Petreus a Physitian of Paris is confuted.

BUT that the truth of this demonstration of *Galen* may be more apparent, let vs a little examine some opinions of the late Writers concerning the use of the Inoculations. *Petreus* is of opinion, that they were ordained rather for the use of the Heart and the whole Body, then for the nourishment and life of the Lungs. And this is the summe of his demonstration, and these for the most part his owne words.

The first intent of Nature is to make all things perfect, but the absolute perfection of her worke she doth not alwayes attaine by reason of the crosse or auerse disposition of the subiect matter, which *Aristotle* calleth the Hypotheticall or materiall necessitie. But what Necessitie constrained Nature to produce these Inoculations of the Vessels? Surely the Necessitie was verie great, which if a Man be ignorant of, he shall neuer vnderstand their Historie. The Use and the Action is the end of Nature when she worketh, and the scope or ayme of the Physitian who searcheth into the workes of Nature, which scope if he neglect

Petreus opin-
ion and de-
monstration.

neglect all Anatomie will be vncertaine, and all his inspection of the part will but double their obscuritie.

Aristotle often admonisheth, that the Organs are made for the Vse, not the Vse applyed to the Instruments; whence it is that *Galen* first propoundeth the Vse and thereto recalleth the Composition and Conformation of euerie part: I will therefore first shew the Vse and necessitie of these Inoculations of the Vessels of the Heart.

The Vmbilicall Arteries doe transmit from the Mother to the Infant Arteriall and Vitall Blood, for they are inserted into his Iliacall Arteries. From these the Blood ascendeth into the trunk of the great Arterie, yea euen to his gate in the Basis of the Heart, where it is constrained to make stay, because Nature hath set at that gate of the great Arterie three Values whereby the passage is bolted from without inward, albeit from within outward any thing may passe. For this inconueniencie & obstacle Nature deuised a present remedy. For considering that the Blood laboured in the left side of the Mothers Heart, and further prepared in the length of his way from the Mother vnto the Infant, was fit for the nourishment of his Lungs; she provided that it should be poured into the Arteriall Veine which is destined for the nourishment of the Lungs. And for that purpose she prepared in the Infant a passage common to the great Arterie and the Arteriall Veine which is conspicuous aboue the Basis of the Heart which we call *Anastomosis*. For the other *Anastomosis* I thus demonstrate the vse thereof.

We before determined that the Arterial Blood which the Infant receiueh from his Mother by the Vmbilicall Arteries, is spent in the nourishment of the Lungs. Now it will be worth our labour to learne how Vitall Blood sufficient to be diffused thorow-out the whole Body is in the Infant generated; for there is no aire led by the Venall Arterie into the left Ventricle of the Heart whereof the Spirits should be made, because the Infant breatheth not in the Wombe, neither getteth any thing into the Heart by the great Arterie, for the Values which open outward and shut inward will admit nothing to enter. The left Ventricle therefore of the Heart had beene vnprofitable through want of matter and the discommoditie of the place, vnlesse Nature had learned of her selfe to frame wayes for her owne behoofe more easie and expedite, which is the other *Anastomosis*, wherein she hath wrought a worke beyond all admiration.

This *Anastomosis* is out of the hollow Veine into the Venall Arterie, by which the Blood (which is too much for the nourishment of the Lungs) is commodiously transported into the left Ventricle of the Heart, where it is laboured, conected and receiueh an impression of the Vitall Facultie, and so turneth aside into the great Arterie which is neere neighbour and toucheth it, that by it it might be distributed into the whole Body.

This demonstration I take to be most true, that the worke of this *Anastomosis* which is a verie miracle in Nature might rather be referred to the vse of the whole Body then vnto an vnprofitable commoditie onely of the Lungs. Neither doe I see by what reason it may be said that the Lungs of the Infant which doe not moue at all whilst it is in the Wombe, should yet then require and dispend a greater quantitie of Aliment and Blood then they doe after the Child is borne, when for the generall behoofe of the Body they are perpetually moued. For if those Inoculations had beene made onely for the Lungs, they being greedy would haue drawne all the Blood by those patent passages which in growne Men they draw onely out of the Arteriall Veine. Furthermore, this absurditie would follow, that the Vitall Facultie of the Heart in the Infant must be idle all the time of his gestation.

This is *Petrus* his demonstration, wherein that I may speake in one word, he establisheth two things: The first that the Arteriall canale or pipe was made for this purpose to poure out into the Lungs alone the Arteriall and Vitall Blood which the Infant draweth by the Vmbilicall Arteries; so that he vnderstandeth that the Vmbilicall Arteries were not made for the vse of the whole Body but onely of the Lungs.

The second thing he would establish is, that the Lungs are not nourished by the Blood brought thorow the hole of the hollow Veine into the Venall Arterie, but that all that Blood is transmitted into the left Ventricle of the Heart for the generation of the Vitall Spirits.

Which two things how absurd they are and dissonant from true and right reason, I will endeavour to shew both by Reason and Sence, which are the two most certaine Iudges of all things.

The summe of
Petrus opini-
on.

Petrus
impugned

In his vse of that communion which is by an Arteriall Canale or Pipe from the great Arterie into the Arteriall Veine; I find some things contradictorie, and verie many false and absurd.

For sometimes he wils, that both the inoculations were made for the vse of the whole Body, not for the commoditie onely of the Lungs; afterward as if he had forgotten himselfe, he writeth in his whole discourse that that Canale which is from the great Arterie to the Arteriall Veine serueth onely for the Lungs: Whereas to make good his demonstration, he should haue said that the inoculation which is from the hollow Veine to the Veball Arterie is to be referred to the vse of the whole Body; but that which is from the great Arterie into the Arteriall Veine, onely to the nourishment of the Lungs. There is therefore in the first place a manifest contradiction; I forbear to say how improperly he calleth the Arteriall Pipe an *Anastomosis*: because I am taught by *Aristotle* not to take too much care of words or to stand too much vpon them.

Galen indeed faith that there are many *Anastomoses* or inoculations of Veines and Arteries, and that an *Anastomosis* is nothing else but an opening of the mouth of one Veine or Vessell into another, and those Medicaments are called *Anastomotica* which haue a facultie to open. We also may vnderstand by *Anastomosis* the confluence of humors made when the Vessels doe open one into another. *Aristotle* in his Booke *De Mundo* (if that Booke were *Aristotles*) vseth the word in another sence, when he calleth the Ocean *ἀνέσσυμος*, which *Budeus* interpreteth in *fauces se comprimitem*: but to call a Pipe, a Tunnell, a Vessell an *Anastomosis*, is a monster in Grammer, in Philosophy and in Physicke. Now *Petrus* words are these: *And for that purpose Nature prepared in the Infant a passage common to the great Arterie and the Arteriall Veine, which is conspicuous about the basis of his Heart which we call Anastomosis.* Let any Man now iudge, yea let himselfe see how farre this nouell speculation of his hath transported him: but this is but to play with him, let vs now set vpon him with keener weapons. He writeth that the Arteriall Blood which the Infant draweth by the Vmbilicall Arteries, is wholly consumed in the nourishment of the Lungs, and that those notable Arteries were onely made for their vse: then which what could he haue said or fained more absurd?

Let him turne ouer all the writings of the *Grecians*, the *Arabians* and the *Latines*, and he shall see that they all accord in this, that the Vmbilicall Arteries were made for the vse of the whole Body not of the Lungs alone. By these Arteries the whole *Embryo* doth transpire and draweth the Mothers spirit, not the Lungs alone. The vse therefore of the Arteries is common to the whole Body of the Infant. And this *Hippocrates* teacheth in his Bookes *De Natura Pueri*, and *De Octimesfri Partu*, in these words: *In the middle of the Flesh is the Nauell separated, by which the whole Infant doth transpire and attaineth his encrease.* Doe not the Arteries in their Diastole or dilatation draw aire, and expell the footie vapors in their Systole or contraction? There are made many inoculations from the Arteries into the Veines, therefore the aire is transported out of the Arteries into the Veines, not out of the Veines into the Arteries.

Galen in his fourth and sixth Bookes *De Locis Affectis*, in his Booke *De Vsu Pulsuum*, in his Commentarie vpon the sixth Section of the Booke *Epidemia*, teacheth vs that transpiration is through the Arteries not through the Veines; and in his first Booke *De Semine*, he saith: *The hole or passage of the Membranes about the Nauell is alwaies open for the transmission of Blood and Spirits, for Blood floweth out of the Veines, but out of the Arteries Spirits with a little thin and hot Blood.* What could he say more plainly, what more perspicuously? This also auoucheth *Auicenna* the Prince of the *Arabians*, and finally it is the vniforme consent of the Schoole of the *Grecians* and *Arabians*: And with vs this common consent of so learned Men shall euer stand for a Law. But *Petrus* one Man, of his owne head taxeth and challengeth all antiquitie of Error. Well, we will therefore no more contend with him with authorities, but by weight of argument.

It is an Axiome in *Aristotle*, that all liuing Creatures doe breathe. For as a Flame pent vp in a strait room and not ventilated or breathed with Aire groweth dimme & at length is extinguished: so our naturall heat is also extinguished vnlesse it be ventilated and waisted with Aire as it were with a fan. This spiration which the *Grecians* call *πνιξ* or *πνικα* is double; the one insensible called *σπνικον*, or *Transpiration*, which is made by the Arteries and other blind breathing holes of the Body; the other may be seene with the Eyes, and is made by conspicuous passages, as the Mouth & the Nofethrils which *Galen* calleth *ἀναπνοή*, *Respiration*.

That

A contradiction in his demonstration.

He vses the word *Anastomosis* verie improperly.

He thinketh amisse that the Vmbilicall Arteries serue onely for the Lungs.

Spiration double. Transpiration & respiration.

The Infant
doth not
respire.

That the Infant in the wombe doth not *Respire* it is most manifest, because he neither ought nor can, as we shall proue in our next Question. It is necessarie therefore that he must haue *Transpiration*, which is not by the Vmbilicall Veine, nor by the *Vrachus*, and therefore by the two Vmbilicall Arteries; for there are no more but these foure Vessels in the Nauell. Wherefore this vse of the Vmbilicall Arteries is common to the whole Infant not proper onely to his Lungs.

That all the
Arterial blood
is not spent in
the nourish-
ment of the
Lungs.

That all the
Arterial blood
is not spent in
the nourish-
ment of the
Lungs.

Now that in the Arteries not onely Aire as *Erasistratus* thought, but also a Vitall Spirit and Arteriall Blood is contained, we are taught by *Experiment* or *Inspection*. The Arteriall Blood then which the Infant draweth by the Vmbilicall Arteries is it not prepared for the life of the whole *Embryo* and the conseruation of the naturall heat? Doth the red and thick *Parenchyma* of the Lungs, not at all as yet moued, stand in need of so great a quantitie of thin and Arteriall Blood? If one Veine which they call the *Nurse of the Embryo*, sufficeth for the nourishment of the whole Infant, why should not one small Arterie haue beene sufficient for the nourishing & cherishing of the Lungs, which are a little part of the Infant? But Nature made two Vmbilicall Arteries and those notable ones, which are branched through the *Chorion* with infinite furcles.

Moreover, if all that Blood which the Infant draweth by the Vmbilicall Arteries were consumed in the nourishing of the Lungs, then these absurdities would follow. First, that the Lungs are not nourished with Blood like vnto their substance, nor with pure Blood. For the Vmbilicall Arteries do returne the Blood into the *iliacke* branches, and from them into the trunk of the *Aorta* or great Arterie; wherefore the Arteriall Blood of the Mother shall be mingled with the Arteriall Blood of the Infant, which he saith is generated in the left Ventricle of the Heart, and thence diffused into the pipes of the great Arterie: and so it will come to passe that one of them shall offend another; for in the same Vessell there shall be at one and the same time perpetually two contrarie motions: one of the Blood ascending from the *iliacke* branches to the Lungs; and another of the Arteriall Blood descending from the left Ventricle of the Heart to the same *iliacke* branches: which thing albeit we confesse, it sometimes hapneth in Criticall euacuations and notable endeauours of Nature: so, that it should be perpetuall we cannot be perswaded. Let vs then wipe away this mist from our Eyes, and let vs beleue that the two Vmbilicall Arteries were made for the vse not of the Lungs alone but also for the whole Body. Now let vs come vnto the vse of the other Inoculation.

His vse of the
other inocula-
tion impugned

Petrens conceit is, that the hollow Veine is perforated into the Venall Arterie, that the Blood might be poured into the left Ventricle of the Heart for the generation of Vitall Spirits, neither doth he acknowledge any other vse thereof. But we with *Galen* thinke that it was formed for the generation and nourishment of the Lungs. For if there be a new generation of Vitall Spirits in the left Ventricle of the Heart, made of the Blood which is conuayed in the hollow Veine as *Petrens* would haue it; then what need was there of that hole or perforation? Doth not the hollow Veine gape into the Heart with a wide mouth to poure abundance of Blood into his right Ventricle? Why is not the Blood there boyled and attenuated, and after sweateth through the partition into the left Ventricle, and there receiue the stampe or impression of the Vitall Spirit? The Blood so attenuated in the right Ventricle would be purer and more defacated, then if it should be transfused out of the hollow Veine into the left Ventricle by that *Anastomosis*; there would haue therefore been no necessitie of Vitall Spirits, but for the nourishment of the Lungs there is absolute necessitie thereof.

2. Reason.

Againe, it is an Axiome in Physicke and Philosophy which *Galen* often beateth vpon, that there is neuer made any perfect elaboration vnlesse a preparation goe before. So the Animall Spirits are prepared in the webbes of the Braine; the Seed is delineated in the writhen complications of the Seed Vessels; the Blood attaineth a rudiment in the Veines of the Mesenterie; and the preparation to the third concoction is made in the small Veines of each particle. But if according to *Petrens* Hypothesis the Blood should be transfused from the hollow Veine into the Venall Arterie which toucheth it, and from that into the left Ventricle of the Heart, where I pray you shall that Blood be prepared or attenuated? If that new conceit of the Generation of Vitall Spirits in the Infant were to be admitted at all, it were more probable to say, that the Blood were poured out of the hollow Veine into the right Ventricle and there prepared, because the Membranes doe not hinder the ingate hereof, and beside the partition is bored with so many passages to conuey it into the left.

left. For it is the opinion of all learned Men, that the right Ventricle was ordained for the preparation of the Vitall Spirits.

Moreover, it is most certaine that there is a double matter of the Vitall Spirit, Aire and Blood. Now *Petrens* doth not thinke that Aire is carryed into the Heart, for the Infant in the Wombe doth not Respire, how then shall that Vitall Spirit be generated & preserued? Out of doubt it will decay and be extinguished being defrauded of conuenient Aliment. *Hippocrates* in his Booke *De Natura Pueri* saith: *Euerie thing that is hot is nourished with that which is moderately cold.* Indeed Transpiration is sufficient to preserue a little heat; but for the perpetuall generation of Vitall Spirits in bloody Creatures there is required great abundance of Aire, which onely can be supplied by Respiration. But let vs pursue these Detractions a little farther.

If we shall admit this new and onely vse of the hole or inoculation, that is, that all the Blood should be conuained from the hollow Veine through the Venall Arterie into the left Ventricle of the Heart, with what Blood shall then the Lungs be nourished? Open the wayes: Shew me the Veine of the Lungs. For now all the Venall Arterie is taken vp, forsooth, to lead Blood vnto the Heart, and the Arteriall Veine only leadeth Vitall Spirits and Arteriall Blood which it receiue from the great Arterie by the Canale or Arteriall Pipe. Shall the Lungs be without Aliment? He will answer, That it is nourished with Arteriall Blood which commeth from the Mother, and that for that purpose the two Vmbilicall Arteries were ordained. But hath he forgotten that all parts want two sorts of Blood, one Venall, another Arteriall? The Venall Blood by true assimilation turneth into the substance of the part, the Arteriall is appointed to conserue, refresh and cherish the naturall heat of the particular parts which is but fugitiue.

I will not deny but some part of the Mothers Arteriall Blood is conuained into the Lungs by the Arteriall Pipe to preserue their life and to defend their naturall heat, but that the Lungs are therewith nourished, I altogether deny. For the Lungs of the *Embryo* are thicker, faster & heauier then they are after the birth, and therefore must be nourished with thicker Blood, for it is a constant truth, that we are nourished with that which is like vnto vs; euen euerie particular part is nourished with that which is most like vnto it.

This Law and Constitution of Nature, *Petrens* by this new Demonstration doth quite abrogate and annihilate, because he appointeth thinner Blood for the Lungs of the Infant which are red, heavy, sad & thicke, then for the Mothers which he must confesse are whiter and thinner. For the Mothers Lungs are nourished with Blood attenuated in the right Ventricle of the Heart, and deriued vnto them by the Arteriall Veine: He stily maintaines that the Lungs of the *Embryo* are nourished with no other then Arteriall Blood laboured and heated in the left Ventricle of the Mothers Heart, & brought vnto them by the Vmbilicall Arteries, forsooth, to make recompence for their want of motion. Here also we haue a manifest contradiction. He confesseth that the Lungs are thinner after birth, thicker in the *Embryo*, and yet he saith that the first are nourished with thicker Blood, the latter with pure Arteriall Blood full of Spirits.

And whereas he buildeth vpon *Galen*s foundations that the Lungs are made of the froth of the Blood, and therefore doe require for their nourishment thin and Arteriall Blood. He seeth not that that place is to be vnderstood of the Lungs after the birth; for in the Infant the Lungs are not frothy nor whitish, but red, heavy and thight, yea euen a while after the birth doe the Lungs remaine heavy and red; whence it commeth to passe that many Infants shortly after their birth are strangled, because the Lungs cannot play themselves, either when the Child lyeth vpon his Backe, or by some compression of his Chest; and therefore it is best to lay Children with their Heads somewhat eleuated or rayled vp, that the Lungs which are heavy may more easily follow the contraction and distention of the Chest.

Those Children which dye so suffocated if they be opened will be found to haue their Lungs full of thicke Blood, and verie red. But let vs heare *Galen* accurately describing the Lungs of a tender Infant in the sixth Chapter of the fifteenth Booke *De Vsu Partium*, in which place he of set purpose expresseth the Historie of the Infant: *Why are the Lungs of an Infant red and not whitish as after birth? Because they are nourished with Blood brought vnto them by Vessels which haue but a single Coat.* And then he addeth: *When the Creature beginneth to respire the Lungs are moued perpetually; whence it is that the Blood being diuided by the double motion of the breath is made thinner then before, and as it were frothy, and so the Flesh of the Lungs*

Arguments
from *anastomosis*.

which before was red, heavy and thight, becommeth white, light and rare or spongy. How pregnant and plaine a place this is, who seeth not? The Flesh of the Lungs of the Infant is red, heavy and fast, and afterward becommeth thinner and frothy: wherefore the Lungs of the *Embryo* stood in need of red and thicke Blood, which kind is onely conuayed by the Rillets of the hollow Veine, not through the thicke Pipes of the great Arterie. But there are no passages from the hollow Veine to the Lungs, and therefore Nature made that admirable *Anastomosis* for the nourishment of the Lungs. And thus *Petrus* ought to haue playd the Philosopher, and not to haue abused that which *Galen* intendeth concerning the nourishment of the Lungs after birth, to the nourishment of the Lungs of the *Embryo*, in the Mothers Wombe. But if he will not yeeld to these Reasons which are cleere demonstrations, then we cite him to the Tribunall of Truth to *avrofiav*, that is, to ocular inspection. Cut the Lungs of the *Embryo* and you shall see all the branches of the Venall Arterie full of red and thicke Blood. From whence, good *Petrus*, is that Blood? Is it not from that hole of the hollow Veine?

We conclude therefore, that that admirable *Anastomosis* or Inoculation was framed by Nature, not for the elaboration of the Vitall Spirit, but for the generation, nourishment and increment of the Lungs. Thus much we thinke our selues bound to haue said, not onely to redeeme the credite of our Master *Galen*, but especially to vindicate and redeeme the truth, albeit it be with the losse of a learned Man, such as we willingly acknowledge *Petrus* to be; but he must be content to suffer himselfe to be gain-sayed if he gain-say the truth; and if any thing fall from vs in discourse which may sound somewhat more harsh in his Eares or those that follow him, that also must be attributed to the heat of disputation: For much may be forgiven a Souldier when he is heated in the medley, which might be imputed to him for crueltie in cold Blood.

The third Exercise.

Another new Demonstration of the use of the Inoculations, denised by Francis Rosset, a learned Physitian belonging to the French King.

Rosset's
opinion
of the use of
the Inocu-
lations.

Aurentius reports, that when Dr. Francis Rosset, the French Kings learned Physitian, heard of this difference of opinions betweene him and *Petrus* concerning the use of the Inoculations, he wrot vnto him that he had found out a new use of both these Communions of the Vessels of the Heart in the Infant, and that he sent also to him this Table which we haue annexed.

His opinion is, that both these Inoculations were ordained onely for the conuaince of Aire, directing it to the Lungs before it should come at the Heart, & mingling it with both kinds of Blood, Venall and Arteriall, prepared before in the Liuer and the Spleene: For as after birth the outward Aire is not carried crude & raw into the Heart, but passing through the Rough Arterie is prepared in the rare substance of the Lungs, and is made fit for the Heart: so in those that be not yet borne, the internall Aire must necessarily come to the Lungs for the same end where it vndergoeth a peculiar Castigation before it be admitted to the Heart. Moreouer, from the thinnesse of that Aire and the pulsatiue motion of the Heart, this commoditie the Lungs must needs haue, that their *Parenchyma* in the Infant and the Vessels therein, are accustomed and prepared to the motions of Expiration and Inspiration which are to follow after he is borne, for the Aire enlargeth the Pores in them, and so fitteth them for the use of the Child when he cryeth.

Wherefore the two Inoculations in the Infant vnborne, and the Rough Arterie after the birth, may be compared to *Caster* and *Pollux*, of which when one aryseth the other is destined to set.

In

IN THE INFANT,

To be borne,

Already borne.

Doe Worke.	Are Idle.	Doe Worke.	Are Idle.
1 The Chorion, the Stomacke being Idle.	1 The Stomacke, the Chorion working.	1 The Stomacke, the Chorion being Idle.	1 The Chorion, the Stomacke working.
2 The Vmbilicall Vessels, the Vessels of the Mesenterie being idle.	2 The Vessels of the Mesenterie, the Vessels of the Nauell working.	2 The Vessels of the Mesenterie, the Nauell Vessels being idle.	2 The Nauell Vessels, the Vessels of the Mesenterie working.
3 The Vrachus, the Vreters being Idle.	3 The Vreters, the Vrachus working.	3 The Vreters, the Vrachus being Idle.	3 The Vrachus, the Vreters working.
4 The Inoculations of the Heart, the Rough Arterie or Weazon being idle.	4 The Weazon or Rough Arterie, the Inoculations working.	4 The Rough Arterie, the Inoculations being Idle.	4 The Inoculations of the Heart, the Rough Arterie working.

The Exposition of the Table.

Euen as the operation at certaine times, and the rest at others, of the three first, to wit, the Chorion, the Nauell Vessels and the Vrachus is answerable to the other three set against them, to wit, the Stomacke, the Mesenterie Vessels and the Vreters, each one respecting his confort or substitute in the administration of one and the same thing necessarie to life: so likewise is there the same succession of operation and rest at different times betweene the foure paire of Conforts, to wit, the Inoculations of the Heart and the Rough Arterie or Weazon, in the administration of one and the same thing necessarie to life.

Rosser his demonstration.

For seeing there can be nothing found nor imagined in the whole Body, which in the Wombe, when the Rough Arterie is at rest, should supply his office which is necessarie to life, vnlesse it be the Inoculations of the Vessels of the Heart; which Inoculations in the Wombe doe worke but cease their labour when the Infant is borne, the Rough Arterie then vndertaking his incessant labour himselfe: it must needs follow that the vse of the Inoculations in the Wombe is the verie same that there is of the Rough Arterie after the Infant is borne. Now all Men acknowledge that the Rough Arterie is ordained for the transvection or transportation of the externall and ambient Aire to the Lungs of the Infant which prepare it, for the Heart standeth in need of Aire so altred. Wherefore the true vse and office of the Inoculations (which onely haue vse whilst the Infant is in the Wombe) is the transvection or transportation of Aire (but that internall comming out of the Mothers Wombe through the Chorion and the Vmbilicall Vessels) to the same Lungs of the Infant which are to prepare it for his Heart.

The last limit is the eleuenth month, the times betweene are the ninth and the tenth.

This is Rosser's opinion, wherein he laboureth to establish, that both the Anastomoses or Inoculations are appointed onely to lead Aire to the Lungs, and that by them the Infant doth respire and the Lungs are moued for the new generation of Vitall Spirits. But our opinion is, that the Infant doth not at all Respire but Transpire onely, as we shall shew in the next Question; neither yet doe we thinke that it was necessarie there should haue been made so notable Inoculations if onely the conueyance of Aire to the Lungs had been necessarie. For seeing in perfect Creatures and those that haue most vse and strength of voice, there is but one Weazon or Rough Arterie ordained, why should not one Inoculation haue serued in the Infant whilst yet he maketh no vse of his Lungs for voice? It had beene more probable if he had said, that one of the Inoculations was made to lead Aire the other to lead Blood. Moreouer, if onely Aire be lead by these Inoculations to the

The 11 the last.
Rosser's opinion disproued.

Vessels of the Lungs, why doth there appeare in the Venall Arterie so red Blood, and in the Arteriall Veine Arteriall Blood full of Spirits? With what Blood shall the red and thicke Lungs of the Infant be nourished? In a tender Infant that Transpiration which is made by the Arteries and other blind passages is sufficient for the conseruation and refection of his weake heat.

The conclusion.

We conclude therefore, that both the Inoculations were originally made to generate and nourish the Lungs, because whereas the Lungs of an Infant before birth doe differ from his Lungs after birth, in colour, thicknesse and fastnesse of Flesh, they needed also an other kind of Blood for their generation and nourishment before then they doe after. And thus we are come to an end of that admirable worke of Nature in the Inoculation of the Vessels of the Infants Heart.

QUEST. XXVI.

Whether the Infant in the wombe doe Respire and stand in need of the labour of his Lungs.

What Respiration is.

Concerning the nature of Respiration we shall haue a fitter place to dispute in the next Booke where we treat of the Lungs. In this place it shall be sufficient to giue you Galens description thereof in his Commentarie vpon the Booke *De Salubri Dieta*, where he saith: *Respiration is, when the breath is drawne in and let out by the Mouth.* So that in Respiration it is necessarie the Chest should be contracted and againe dilated, and the Lungs moued thereafter. If therefore I shall proue that in the Infant the Chest is not contracted or dilated, nor the Lungs moued, it will follow that he doth not Respire but Transpire onely.

That the Infant doth transpire onely and not respire in the Wombe.

The Vitall Facultie in bloody and hot Creatures stands in need of two things for the conseruation thereof: Respiration and Pulsation. But those Creatures which are without Blood and imperfect, which haue little heat, doe liue contented onely with the pulsation of the Arteries and Transpiration. So those we call *ivroua* and which liue in holes all Winter doe Transpire but Respire not. So likewise *Hysterical* Women, that is, such as are in fits of the Mother, the heat of whose Heart is languid and weake being dissolued by a venemous breath of corrupted Seed, doe liue a time without Respiration, and many haue been buried for dead when they were yet aliue.

The Infant neither ought, nor can respire

The Infant because he hath but a weake heat, and is in the Wombe before the day of his birth as it were an imperfect Creature, is contented onely with Transpiration, and therefore he draweth not his breath by his Mouth, neither vseth he the helpe of his Chest or Lungs. For Respiration is onely ordained for the behoofe of the Heart, that the spirituous substance which is wrought in the glowing hot left Ventricle might with the Aire be cooled as it were with a Fan, and beside purged and refreshed; but there is no generation of Vitall Spirits in the Infant, as by and by we shall demonstrate: and therefore there is no need of Respiration; for the finall cause sayling which moueth all the rest, Nature is too wise to vndertake any labour. The Infant therefore doth not Respire because he ought not. Add hereto that he neither can Respire: for being shut vp in his Mothers Wombe and compassed about with Membranes, if he should draw in breath at his Mouth with the aire he should also draw in the Water wherein he swimmeth, and at the first draught would be so suffocated as they that are drowned in a Riuer. Again, he hath no Aire that he might draw, for there is no space in the Wombe that he doth not fill, and beside the Orifice of the Wombe is so close locked vp that it will not admit a little wind to enter into it. Again, that no Aire is inspired by the Mouth or the Nofethrils, the substance and colour of the Lungs doe sufficiently declare. For all Creatures which draw Aire at their Mouthes and Noses haue white and thin Lungs, but the Lungs of the Infant, as hath been often said, are red and thicke, and are nourished with red and thicke Blood brought vnto them by Vessels hauing single Coats, that is, by Veines. Wherefore the Infant doth not Respire, because neither ought he if he could, nor can if he ought. *Rosset* objects, that by both the Inoculations there is plentie of Aire transported to the Infants Lungs, because it dilateth and contracteth his Chest. But if that were so, then should it follow that the Chest is moued after the motion of the Lungs; for the Lungs being puffed vp by the Aire inspired should enlarge the Chest; and againe falling vpon the expiration of the Aire should compresse the

Rosset objection answered.

the same. So the Lungs should not be filled because the Chest is distended as it is in a paire of Bellowes; but because the Lungs are filled the Chest should be distended as it is in a Bottle or Bladder, which to say were verie absurd, as *Galen* teacheth in a thousand places. For the Lungs follow the motion of the Chest for the auoiding of vacuitie, as in the next Booke we shall more plainly proue.

Neither is the distention and contraction of the Chest simply necessarie for the maintenance of life; for those Creatures which lurke in holes all Winter, we call them *χρυεῖς*, and some Women doe liue without that motion of the Chest. Respiration therefore in the *Embryo* or young Infant is not absolutely necessarie.

Some there be, who thinke that Infants doe Respire in the Wombe as diuing Fishermen, who will remaine more houres then one in the bottome of the Water, and returne fresh vp and laden with Fish. Why should not the Infant being warme in the Wombe as well liue, his Weazon haply a little helping him, as the cold Fisher draw Aire out of himselfe with his Mouth being compassed round about with cold Water? The same thing also they confirme by the authoritie of many authentick Authors. *Hippocrates* in his Booke *De Natura Pueri* saith: *First the Infant breatheth a little and draweth a little Blood from the Wombe; and his breathing is increased when he draweth more Blood, it descending more plentifully into the Wombe.* *Galen De Locis Affectis*: *If the Heart be deprived of Respiration, the Man must of necessitie instantly perish.* Is not the Infant a Man? Furthermore, Women feele their Infants to moue with Animall and voluntarie motion: Why therefore are not the Lungs and the Heart moued? As therefore in the first months when the Infant beginneth to moue, he is truly said to moue though it be obscurely: so though he breathes obscurely, yet he may truly be said to Respire. *Galen* in his fourth Booke *De Causis Pulsuum* saith: That Women with Child haue greater, quicker and swifter Pulses then they haue when they are not with Child; because they are compelled to breathe not onely for themselves but also for their Infants. But all these things doe proue indeed that Infants doe Transpire, but they doe not proue that they doe Respire. For, in respiration the Chest is contracted and distended, and Aire is breathed in by the Mouth and the Nose; which that it is not so in the Infant we haue already demonstrated. Indeed by the Vmbilicall Arteries there is Aire transported together with the spirituuous Blood into the whole Body of the Infant, and from the Arteries there are many Inoculations into the Veines; whence it cometh to passe that though the Arteries be tyed, yet the Creature doth not presently dye as being a while sustained by that Aire which the whole Body receiueth from them.

Respiration is not absolutely necessarie to life.

That the Infant doth respire. A comparison

Authorities.

The Solution of the arguments.

QUEST. XXVII.

Whether the Vitall Facultie which procreateth the Spirits is idle in the Infant, and whether his heart is moued by it owne proper power. A Paradoxe.

Concerning the life of the Infant, that is, how he exerciseth his Vitall Faculties there is a new Paradoxe, which we will discusse. I doubt not but at the first view it will seeme to many Men absurd, but if it be better attended I presume it will appeare so strong and so well supported with strong demonstrations that it will be hard for a contentious Spirit to shake them. The Paradoxe is this: *There is in the Infant no necessitie of the Lungs and the Heart, because he liueth without their officiall action.*

A paradoxe, that the Vitall Faculty of the heart in the Infant is idle.

This if I can proue, I shall ouerthrow the iudgement and determination of *Aristotle* and the *Peripateticks* concerning the foueraigntie of the Heart in Mans Body. The demonstration of our Paradoxe shall be wholly Physiologicall and Anatomicall.

The demonstration.

The Faculties of the Soule are reckoned by *Aristotle* to be three: The Vegetatiue, the Sensatiue and the Intellectuall. The Physitians account so many, but giue them other names: The Naturall, the Vitall and the Animall. That which the *Peripateticks* call the Vegetatiue differeth nothing from the Physitians Naturall: for as we say, the whole Naturall Facultie is contained in the *Increasing, Nourishing* and *Procreating* Vertues: so *Aristotle* in his second Booke *De Anima* saith: That the same vertues serue the Vegetatiue Soule. This Vegetatiue Facultie is common to all things that are animated, that is, which haue any kind of life in them, and proper to them onely. For all things that haue life are nourished, but the Vitall Facultie of the Physitians, which is the procreator of the Spirits of life, which shineth

in Respiration and in the Pulse, doth not appeare in Plants and things without Blood, because their cold and crasse Spirits are scarce at all expended or wasted. In hotter Creatures there was need of a Fire-hearth, from whence the vanishing heat of the particular parts might be redintegrated & refreshed by the influence of another. That lively and quickning *Nectar* is the Vitall Spirit which the Heart ἀρχὴ τῆς θερμότητος καὶ τῆς ζωῆς, the originall of heat and life, continually generateth of Blood and Aire mingled together by his admirable motion; as a Water-Engine worketh vp a Stream. That this Vitall Facultie of the Physitians doth not shine in the Infant neither yet his Heart moue by a proper & ingenite power although he liue, we are fully perswaded by these Arguments.

The first
argument.

What neces-
sitie there is
of the motion
of the Heart.

The Heart is moued to generate Vitall Spirits, and the same to diffuse out of his left Ventricle as out of a liuing Fountaine to the Canales of the great Arterie to refresh the fading and decaying heat, to supply by his fource of Vitall Spirits the liuelode of the particular parts. This is all the necessitie of his perpetuall motion, this the Finall cause. But in the Infant there is no generation of Vitall Spirits in the Ventricles of the Heart, neither are Vitall Spirits deriued from his Heart into the Arteries; Ergo his Heart moueth not, there being no necessitie of the motion.

The *Maier* Proposition of it selfe is cleare enough. For who seeth not that in the Diastole or distension of the Heart, both the matters of the Spirit Aire and Blood are drawne into the Heart? The Aire by the Venall Arterie into the left Ventricle, the Blood by the hollow Veine into the right. Againe, that in the Systole or contraction of the Heart both the sootie vapors which are the recrements of the Spirit are purged, and the Vitall Spirits driuen into the Pipes of the great Arterie as into water-courses. Insomuch that this generation of the Spirits which it accomplisheth by his perpetuall motion seemeth to be the onely official action of the Heart. The *Minor* Proposition is thus confirmed.

There is no
generation of
Vitall Spirits
in the Infant.

The Vitall Spirit is generated of Aire and Blood mingled together. Both the matters before they attaine the left Ventricle of the Heart doe stand in need of preparation. The Aire by his aboad in the substance of the Lungs attaineth a qualitie familiar to the in-bred Spirit. The Blood is prepared in the right, which they call *σπέρμα* and the bloody Ventricle. But in the Infant there is neither any plentie of Aire conuained into the Lungs (for the Weazon is idle) neither is there any Blood poured into the right Ventricle. There is therefore in the Heart of the Infant no Shop nor worke-house of the Vitall Spirits. That neither Aire nor Blood is deriued into the Ventricles of the Infants Heart is manifestly proued by the structure of his Vessels. For the Vessels are vnited; the hollow Veine and the Venall Arterie by a large hole, the great Arterie and the Arteriall Veine by an Arteriall Pipe or Canale: wherefore the hollow Veine doth not poure Blood into the right Ventricle, as it doth after we are borne, but into the Venall Arterie thorow that hole for the nourishment of the Lungs. The Venall Arterie leadeth not Aire but Blood, and that thicke and venall. The great Arterie doth not draw Spirits from the Heart but from the Vmbilicall Arteries, which it transmitteth by the Arteriall Pipe into the Arteriall Veine.

Now if the Vitall Spirits were generated in the left Ventricle of the Heart, what need were there of that Arteriall Pipe, seeing there is in the Heart a wide vessell which is diuersly dispersed thorow the whole substance of the Lungs, I meane the Venall Arterie? This surely is a strong demonstration whose force no Man can perceiue, vnlesse he be skild in Anatomy, for it dependeth wholly vpon ocular demonstration, and the credite of a Mans owne sight. But this we will establish by other reasons.

The second
argument.

There is no
necessitie of
new Vitall
Spirits.

There is in the Infant no necessitie of that common Store-house or worke-house of the Spirits, because the two Vmbilicall Arteries doe supply vnto him Arteriall Blood; and a sufficient proportion of Vitall Spirits and those verie pure and bright, as being made by the strong heat of the Mothers Heart. Nature doth nothing idly or in vaine, why therefore should she make two Vmbilicall Arteries if new Arteriall Blood were to be generated in the Infants Heart? You will say that the Mothers Arteriall Blood was vnprofitable, and not so fit for the vse of the Infant, and therefore it needed to be re-boyled by his Heart. But I desire to be shewed the wayes whereby that Arteriall Blood can be transmitted into the left Ventricle; by the mouth of the great Arterie it cannot passe togetherward because Nature hath bolted it with three Valves which looke from within outward; albeit we thinke with *Galen* that some small quantitie of the Blood sypeth into the Heart to nourish it and preserue his life. From the great Arterie it is freely poured into the Arteriall Veine through the Arteriall Pipe, but from the Arteriall Veine into the Heart there is no way

open:

open: for the Membranes or Values of this Vessell are open outwardly but closed within, which giue way to any thing that commeth out of the Heart, but doe intercept the returne of it into the Heart. Seeing therefore that the Arteriall Blood of the Mother doth not forsake the Arteries, neither hath any access vnto the left Ventricle of the Infants Heart, we cannot admit any new preparation of the old, or preparation of any new.

Againe, if the Spirit of the Mother and the Arteriall Blood be prepared for the nourishment of the Lungs, and for the conseruation of their heat, as *Petrus* would haue it: why also should not the other parts of the Body liue by the influence and illustration of the same Spirit? Or if the Heart of the Infant doe generate Vitall Spirits whereby the life of the whole is preserued, why shall it be thought insufficient for the preseruation of the Lungs which are but a little part of the whole? Wherefore the Infant truly liueth by his owne proper life, but he neuer engendreth new Spirits nor hath any vse of the motion of the Heart. Notwithstanding we must not say that therefore the Heart is idle, for Philosophers say, that is onely idle which doth not worke when it ought and when it can.

The third Argument

Why the heart of the Infant cannot be said to be idle.

The Heart of the *Embryo* neither can make Vitall Spirits, nor ought if it could. It ought not, because the two Vmbilicall Arteries doe supply both a sufficient number of Spirits and those also verie pure: neither can it, because there is a want of matter, for it hath no Aire which it should draw.

As therefore we doe not acknowledge any new Chylification or Sanguification in the Infant (for where should the Recrements of either of them be reserued or treasured for seuen months together.) So neither doe we admit a new generation of Vitall Spirits in the Heart of the Infant. But you will obiect, that Infants Arteries are moued, and all motions of the Arteries are from the Heart, because the Heart and the Arteries are continued together. Wherefore if the Arteries be moued together with the Heart, it will follow necessarily, that we must admit in the Infant the Vitall Facultie by which the Spirits are ingendred.

Obiection.

Answer. The Arteries of the Infant are moued after the motion of the Mothers Arteries. The first demonstration.

I answer, that the Arteries of the Infant are indeed moued, but that their motion followeth or floweth from the Arteries of the Mother, so that his Arteries doe not bear by a proper and ingenite facultie of their owne, nor by any power issuing from his Heart, but by a force and efficacie transmitted from the Heart and the Arteries of the Mother. That these things are thus, this elegant demonstration I thinke will sufficiently proue. It is most certaine that the Veines and the Arteries of the Wombe doe so adhere to the Veines and Arteries of the *Chorion*, that both Arteriall and Venall Blood doe flow out of one vnto the other. And this continuitie of the Vessels, *Galen* maketh often mention of, for in his Booke *De Dissectione Vteri*, he saith, *The end of that Vessell which is propagated thorow the Wombe, giueth beginning to that which is in the Chorion, so that you may call these two one Vessell*, for their mouthes are so vnited, that the Veine draweth Blood from the Veine, and the Arterie Spirit from the Arterie.

Answer.

If this be true in the Arteries so opening into the mouthes either of other, it must needs follow that the end of the Arterie of the Mothers Wombe when it beateth must driue Arteriall Blood into that part of the *Chorion* which is continuall therewith, otherwise that Arteriall Blood must either recoyle into the Wombe out of the which it is issued, or else there must be a conculcation of two Bodyes confused and mingled in the same time and place, mutually penetrating one the other; whence it shall come to passe, that if we grant there is a Dilatation in the *Dyafole*, we must also yeeld that there is at the same time and in the same Vessell a compression in the *Systole*.

The second

Furthermore, is it not true which the Philosopher so often vrgeth, that a part of that which is continuall being moued, the whole is moued vnlesse it be hindred? The Arteries of the Infant are continued with the Arteries of the Mother; therefore when the Mothers Arteries are dilated, it is of necessitie that the Arteries also of the *Chorion* must be dilated. But if that Pulsatiue Facultie did flow from the Heart of the *Embryo*, there should flow also Vitall Spirits from the left Ventricle into the Arteries of the Infant, which alwayes be accompanied with Arteriall Blood, and so the Arteriall Blood of the Mother should be alwayes mixed with the Arteriall Blood of the Infant; and there should be a double motion in the Arteries of the Infant, one from the Heart of the *Embryo*, the other from the Mothers Arteries which would not be answerable but contrarie the one to the other.

We conclude therefore, that the Arteries of the Infant are moued after the Mothers Arteries.

Arteries, because they are continued with them: and therefore that that Vitall Facultie which procreateth the Vitall Spirits and the Arteriall Blood, must by no meanes be admitted to be in the Infant.

*Galen's
opinion*

Galen sometimes seemeth to haue beene of this opinion: for in his Booke *De Formatione Fetus*, he saith, That the Infant liueth after the manner of a Plant, and therefore standeth neither in need of the action of the Heart nor of the Braine, as neither of the Eyes nor of the Eares. As therefore a Plant oweth all his life vnto the Earth, so the Infant oweth all to the Mother. Yea sometime he saith, that the Infant is as it were a part of the Mothers body. As therefore a part of the Body needeth not any particular respiration, nor any particular Stomacke to digest his Aliment, yet of necessitie requireth the pulsation of Arteries: so the Infant liueth contented onely with transpiration, which is accomplished by the *Diastole* and *Systole* of the Arteries.

Galen.

In the 21 Chapter of his sixth Booke *De Vsu Partium*, *Galen* saith: We need not wonder that the Heart of the Infant to his proper life needeth but a little Spirit, which he may draw out of the great Arterie, seeing it sendeth neither Blood nor Spirits to the Lungs nor to the Arteries of the whole Body as it doth in perfect Creatures. Where marke that he saith, The Heart may draw a little out of the great Arterie. For the Values or Flood-gates there set by Nature, doe not hinder a little Arteriall Blood and Spirits from sypping into the Heart, but they hinder a sudden and plentifull confluence, such as should be necessarie, if of them the Heart should make Vitall Spirits and Arteriall Blood for the whole Body of the Infant.

*The contrarie
opinion.
That the Ar-
teries of the
infant are mo-
ued by a pow-
er issuing from
his Heart.
Authorities
out of Galen:*

This I say was *Galen's* opinion: yet in many places he seemeth to say the quite contrary: that the Arteries of the Infant are moued by a facultie sent from his Heart vnto them, and that the Heart it selfe is moued by an in-bred and proper motion. In the 22 Chapter of the seventh Booke *De Vsu Partium*: The Heart (saith he) not onely in perfect Creatures but also in Infants supplyeth to their Arteries the power by which they are moued. And in the 21 Chapter of the sixth Booke: If you tye the Arteries of the Nauell whilst the Infant is in the Wombe, all the Arteries which are in the Chorion will cease beating, and yet those Arteries which are in the Body of the Embryo will continue their pulsation: but if with the Vmbilicall Arteries you tye also the Vmbilicall Veines, then will the Arteries which are in the Body of the Infant leaue beating also. By which it is manifest, first that that power which moueth the Arteries of the Chorion proceedeth from the Heart of the Infant: Againe, that the Arteries get Spirits from the Veines by their Inoculations. In the same Booke in another place he saith: The Heart in the Infant when it dilateth it selfe, draweth Blood and Spirits from out of the Venall Arterie. In the ninth Chapter of his Booke *De Formatione Fetus*: When the Heart of the Infant cometh to haue Ventricles, and hath receiued Venall and Arteriall Blood, then it pulseth, and together with it selfe moueth the Arteries, so that it liueth now not onely as a Plant, but also as a Creature. This opinion may also be confirmed by reasons.

*The first
Argument*

Seeing the Heart is the hottest of all the Bowels and as it were a Fire-hearth, if you de- priue it of motion it hath nothing left wherewith it may be refrigerated; by transpiration it cannot, because it is included in a hot and narrow roome; nor by the appulsion of exter- nall aire, for the soliditie and thightnesse of the Membranes wherewith it is compassed hinder the access thereof: add hereto that those warry Excrements in the *Pericardium* doe hinder the perspiration. Neither hath the Heart of the Infant any refrigeration from the Mothers Arteries by the access of a new Matter or Spirit, for nothing can arriue into the Heart of the Infant from his Arteries because of the Membranes which lye vpon the mouth of the great Arterie.

*The second
argument.*

*Histories
of many cut
out of their
Mothers
Wombes.*

The motion therefore of the Heart was necessarie, by the benefite whereof both Blood and Spirit are drawne into it, and from thence communicated to the whole Body. The credite also of this opinion is encreased by Histories: for many Women report that some haue beene cut out of their Mothers Wombe after they were dead and so saued; as *Scipio* and *Manilius*. The Ciuill Lawyers doe condemne him as a Murtherer that shall bury a Woman great with Child before he hath taken the Infant from her, because together with the dead Mother he seemeth, or is held in construction, to haue buried a liuing Infant: which Law being made with the consent of Physitians, doth sufficiently declare that the Infant may suruiue after the Mother is dead. It is reported that *Gorgias* the *Epirote*, after his Mother was dead and vpon the Bier to be buried, issued aliue from her wombe, which could not haue been vnlesse the Heart of the Infant had had in it Vitall facultie, which with- out the assistance and communion of the Mothers Heart for a while did sustaine his life.

But

But I thinke it will not be hard to giue a sufficient answer to all these Authorities and Arguments. For *Galen* authoritie we make the lesse account of it, because it contradicth himselfe. Moreouer, we say that the experiment which *Galen* biddeth vs try is impossible, for you cannot intercept the Vmbilicall Veine and Arteries of the Infant vnlesse the Mother be dead & her Wombe opened, and then we say the Infant doth respire not transpire. And whereas they say that the Heart hath not wherewith it may be refrigerated vnlesse it be moued. We answer, that the Infant contained in the Prison of the Wombe, hath sufficient for the preservation of his life from the Mothers Arteries, because it liueth as those Creatures doe, which the *Grecians* call *ομαλόντα ζῷα*, beside it receiueth some refrigeration from the luke-warme Water wherein it swimmeth.

Answers to the Authorities and arguments.

The last reason from the cutting out of liuing Infants out of their dead Mothers, may seeme to some to vrge much, but the answer is at hand. That the Vitall Facultie diffused through all the Arteries, without the communion of the Heart may for a short time preserue the Infant alieue after the Mothers death.

We haue seene (saith *Galen* in his second Booke *De Placitis*) a sacrificed Beast walke after his Heart was taken away, and haue often made experience of the same in a Dogge. What also if I shall say, that those Mothers were Hysterical and esteemed as dead when yet they were alieue, which thing is not vnusuall? The truth therefore of our opinion remaineth firme, that the Heart and the Arteries of the Infant doe pulse or beat from a power proceeding from the Heart and Arteries of the Mother, not from any proper and ingenite facultie of their owne, and that no new Arteriall Blood is generated in his left Ventricle, seeing the Mothers Arteries doe supply a sufficient quantitie, and that verie pure.

Galen.
The Conclusion.

From hence let the *Peripateticks* learne, how vnadvisedly *Aristotle* calleth the Heart the first Liuer, Mouer and Blood-maker. For both the Arteries of the Infant doe moue before his Heart, and the Heart liueth onely by the pulsation of the Arteries. Finally, as long as the Infant is included in the Wombe of his Mother, we doe not beleue that his Heart is the Shop or Store-house either of Vitall Spirits, or of Arteriall Blood.

Against the Peripateticks principally of the Heart.

QUEST. XXVIII.

Whether there be in the Infant any generation of Animall Spirits, and what position the Infant hath in the Wombe.

THE Mouing Facultie floweth into the Flesh of the Muscles from the Braine by the Nerues, not by a simple irradiation or separated qualitie, but by a Corporeall Substance, which the Physitians call *Animalem Spiritum*, an *Animall Spirit*. Seeing then the Infant in the Wombe moueth of his owne accord some times to the right side, some times to the left, and often times kicketh with his Heeles, it followeth necessarily that he hath Animall Spirits. But whether he draweth these from his Mothers Wombe as he doth the Vitall, or generateth them in the webbes or substance of the Braine by a proper and in-bred facultie, it hath of long time been a great question. I thinke that they are generated in the Braine, and my reasons are these: Because there is no communion or connexion betweene the Nerues of the Wombe and of the Infant, as there is betweene their Veines and Arteries. Now onely the Nerues conuey the Animall Spirits.

The generation of the animall spirits in the Infants.

You will obiection, that the Animall Spirit standeth in need of Aire for his conseruation and expurgation, but no Aire is inspired as long as the Infant is in the Mothers Wombe.

Obiection.

I answer, that this Animall Spirit is cherished, purged and tempered by that transpiration which is made by the Vmbilicall Arteries, but his generation we thinke to be the same in the Wombe that is after the Infant is borne, which how it is we shall declare more at large in the seuenth Booke where we shall of purpose entreat of it.

Solution.

Concerning the time of the Infants motion, *Hippocrates* seemeth not alwayes of one mind. For in his Booke *De Morbis Mulierum* he saith, *That Male Children moue the third month, and Females the fourth.* But in the third Section of his second Booke *Epidemion* he saith, the Infant is moued the 70 day, in these words: *whatsoever is moued the seuenth day is perfected in the triplicities.* And in his Booke *De Nutritione*: *Thirtie dayes forme the Infant, seuentie moneth it, and two hundred and ten perfect it.* You may reconcile *Hippocrates* to himselfe in my opinion, if you say, that there is one motion obscure, another so manifest that

In the time of the Infants motion *Hippocrates* varieth.

The places reconciled.

the

That the Infant may moue at eight weekes

Concerning the position of the Infant, different places reconciled.

A diuers reading in Hippocrates.

How both readings are made good.

the Eye may iudge of it and the Hand may feele it if it be layd vpon the Belly. In 70 daies the Infant may moue, but the motion shall be neither visible nor to be felt till after the third or fourth month. And surely my selfe haue knowne a Woman in three Children confidently auouch, that after eight or nine weekes she hath alwayes felt her Infant moue verie sensibly, which I could not belieue, till I had well considered of this place in *Hippocrates*.

Concerning the position also or scituation of the Infant in the Womb, which is referred to the mouing Facultie, there are some places which need to be reconciled. *Hippocrates* in his Booke *De Natura Pueri* saith, that in the wombe the Infants Head is neere vnto his Feet. *Thou canst not iudge* (saith he) *though thou shouldst see an Infant in the Wombe, whether his Head be placed above or below.* But in his Booke *De Oetimestri Partu* he writeth, that the Head is placed in the vpper part of the Wombe, in these words: *All Infants are begotten hauing their Heads upward.* *Aristotle* in the eighth Chapter of his seuenth Booke *De Natura Animalium*, seemeth to reconcile these places on this manner: *All Creatures* (saith he) *in the first months after their Conformation beare their Heads upward, but when they increase and grow toward their birth, their Heads bend downward.* Againe, in *Hippocrates* Booke *De Natura Pueri* almost all Copies haue it thus: *The Infant seated in the Wombe hath his Hands at his Cheekes.* Yet all Interpreters translate it *Ad Genua, At the Knees.* I thinke that both Readings may be maintained: For there are some Copies of both Readings. For the Infant hath his Hands at his Cheekes and at his Knees. The palmes of his Hands take hold on his Knees, and the backs of his Hands touch his Cheekes. For, if as *Aristotle* writeth in the place next before quoted, the Infant is so rowled vp that his Nose is betwixt his Knees, his Eyes vpon his Knees, his Eares on either side his Knees, and that with his Hands he takes hold of his Knees, he must necessarily rest both his Cheekes vpon his Hands. Those things some haue written of the different scituation of Males and Females, are but deuices of their owne Braine. But those things which *Aristotle* hath written in his seuenth Booke *De Natura Animalium*, concerning the different scituation of diuers Creatures, are well worth the obseruation and our knowledge: Notwithstanding, I doe not thinke fit to transcribe them here, but referre him that desireth satisfaction vnto *Aristotle* himselfe.

And thus much shall be sufficient to haue spoken of the Infant all the while he is contained and contenteth himselfe with the Prison of the Wombe: it remaineth now in the last place, that we speake of the birth of the Infant.

QUEST. XXIX.

Of the nature and differences of the Birth.

WE now enter into a vast Sea, a huge and enorme Tract when we vndertake to dispute of the Nature, Times & Causes of the birth of Man; wherein we shall meet with many contrarie gusts of opinions, many vnpassable and thorny wayes. How many reciprocall Waues in the concertations of the Ancients? How many Quick-sands in the accounts of months and dayes? How many Rockes in the search after the causes of things? Amongst which vnlesse a Man be well steered by Reason, he must needs set vpon some misadventure. Notwithstanding, so necessarie and profitable a Voyage this is, as we will aduenture our selues; the Pole we are guided by is fixed Truth, and the Pilot shall be *Hippocrates*, who as saith *Macrobius*, *Could neuer deceiue or be deceiued*: out of his Bookes *De Septimestri & Oetimestri Partu, De Natura Pueri, De Principijs, De Alimento, and De Morbis Mulierum*, will we draw our Demonstrations.

But that we may proceed in order through the whole course of our Disputation, that the capacities of such as are not thorowly grounded may not be confounded, we will diuide our Discourse into three Heads. In the first we will open vnto you the Nature of the Birth and all the differences of the same. In the second, we will handle the Times of the Birth by a computation of the yeeres, the months and the dayes. In the last place, we will manifest the Causes of the varieties of the Birth, as well the Generall as the Particular, the Naturall, the Physicall, the Arithmetically, the Gometricall and the Astrologically Causes.

To begin therefore with the first. The Birth, which the *Grecians* call *τόκος*, we define to be an Edition or bringing into the world of an Infant perfected & absolued in the wombe,

Three heads of the question.

so that whatsoeuer month, day or houre the Infant arriueth into the World, that arriually may properly and truly be called the birth. To this perfection we speake of, there is required not onely a Dearticulation of the Parts, for then if a Woman should miscarrie at foure months that miscarriage should be called a Birth; but also their strength and growth, which because the Infant attaineth not before the seuenth month, we cannot properly call it a Birth before the seuenth month, but either an abortment or a miscarrying. An Abortment the *Grecians* call by diuers names, ἀποθράν, ἀμβλωσις, διαθράν, ἐκτρωσις, ἐμβελόν, ἐκτρωμα, κύημα ἀνεμαίον. We therefore define an Abortment to be either the issuing of an imperfect Infant or his extinction and death in the Wombe. Some there are who will not haue it called an Abortment before the Infant hath moued, so that a Woman shall not be said to abort but from the third month to the seuenth, and that before the motion it shall be called an Effluxion or miscarriage.

What is required to a perfect birth.

The names of the Abortment.

The definition.

The error of some.

But these Men seeme to me not to conceiue *Hippocrates* meaning aright: For *Hippocrates* after the *Embryo* is formed vseth to call it an Abortment if it come before the due time, whether it be before the motion of the Infant or after it. As in the 44 Aphorisme of the first Section: *Those women that are too much extenuated doe abort at two months.* And in the Aphorisme following in the same Section: *Those that are naturally disposed doe abort at three months.* But if the Geniture be auoyded before Conformation, then is it not properly called an Abortment, but *εκπαις*, an Effluxion, so saith *Hippocrates* in his Booke *De Septimestri Partu*: *Those corruptions which happen a few dayes after the Conception, are called Effluxions not Abortments.* *Aristotle* also in the fourth Chapter of his seuenth Booke *De Natura Animalium*, calleth those corruptions which fall out before perfect conformation, *Effluxions*. Wherefore some say that *Hippocrates* is not to be accused of impietie or of breach of his oath, because he counselled the dancing Dame he calleth *Psalteria* to prouoke an Abortment, because she lost not an Infant, but suffered onely an Effluxion seuen dayes after she had conceived.

Hippocrates.

What an Effluxion is.

Hippocrates ill excused.

But howsoeuer we in Schooles may distinguish thus nicely, yet God iudgeth after another manner as we may perceiue by his iudgement vpon *Onan*. Neither doe we by Abortment onely vnderstand an exclusion of an imperfect Infant, but we say that a Woman may abort in her Wombe though the *Embryo* be not brought away: So saith *Hippocrates* in his first Booke *De Morbis Mulierum*: *When a woman aborteth and the Infant is not excluded.* So that Abortment signifieth not onely an exclusion of the Infant before the due time, but also the extinction or death of the same in the Wombe before the due time of birth. For an Infant may be carried in the Wombe after he is dead many yeeres, as may be proued by many examples. Among the rest that is notable, of the Infant which the Mother bare in her Wombe 28 yeeres which was turned into a Stone, as it is recorded by *Iohannes Albosius* a learned Physitian. Likewise, that about *Newarke* not many yeeres since, which after it dyed in the Mothers Wombe remained there a good space, and after was vomited vp by peece-meale out of the Stomacke: a Storie past all beleefe fauing that it hath so many Eyewitnesses yet living and ready to iustifie the truth of it. Thus we see out of *Hippocrates*, what is a Birth, what an Abortment, and what an Effluxion. To wit:

His large acceptance of an abortment.

Two strange stories.

Octimestris partus is not an abortment.

Birth is when an Infant perfected in the Wombe commeth into the World whether it issue aliue or dead: so that they are in no small error who call the Infant of eight months old an Abortment, because it is not aliue: for it is not simply and absolutely of the essence of the birth that the Infant should be borne aliue, but that it should be borne perfect, now at eight months it is perfect. To be aliue or not aliue, to be legitimate or not legitimate, are differences of the Birth as we shall say by and by. An Abortment is an exclusion or extinction of an vnperfect Infant. An Effluxion or miscarriage is an auoyding of the Geniture before perfect conformation.

The differences of the birth.

The first condition required in a naturall birth.

Having thus made plaine the nature of the Birth, we come now to the differences thereof. A Birth is either Naturall or not Naturall, Legitimate or Illegitimate. To a Naturall Birth three things are required: The first, that there be an equall contention of the Infant and the Mother. For the action of the birth is common both to the Infant and the Mother. But to which of these we ought to attribute the beginning of the motion, whether to the Wombe or to the Infant, *Galen* expoundeth in his Commentary vpon the 37 Aphorisme of the fifth Section: *The Infant bringeth to the Mother the beginning of the Birth.* For being become larger and hotter and needing more store of Aliment and Spirit, with often and violent motions of his Hands and Feet he breaketh the Membranes, and the Wombe

OUCE-

ouer-burdned with so great a weight and so vnruely an Inmate, desiring to lay downe her vnwealdy burden, wholly contracteth it selfe to the shutting out of the Infant: So that from an equall contention of the Infant and the wombe, the Birth proceedeth *natura quoniam, according to Nature*. But if neither of them endeauour, or but one of them fayle, then is the Birth *not Naturall*. For if all the worke lye vpon the hand of the Mother, then is the Birth hard and laborious; Now that hapneth when the Infant is weake, or his strength spent, or he be dead; which *Hippocrates* expresseth in these words, in his first Booke *De Morbis Mulierum*: *The Birth is then most difficult when the Infant issueth either dead or apoplecticall*, that is, depriued of motion and sence.

The second condition.

A description of the naturall figure.

Why the head forward is the most naturall figure.

Why dead men are caried with their feet forward.

Diuers vnaturall figures of the birth.

Agrippa why so called.

The third condition.

The second condition of the Naturall Birth is, that it come forth in that figure which is according to Nature. This figure *Hippocrates* first of all Men described in his first Booke *De Morbis Mulierum*, and in his Booke *De Natura Pueri*, and *De Octimestri Partu*: *The Child commeth with his Head forward if he come according to Nature*. Now why this figure and forme of issuing is according to Nature, *Hippocrates* rendreth a reason. *Because the Infant hanging vpon the Nauell as a Ballance vpon a Beamie, his upper parts are the heauier*, and therefore his Head turneth sooner downward. Add hereto that if the Infant come with his Head forward, the rest of his parts being flexible like Waxe doe not hinder the Birth but yeeld and giue way vnto it: But if he come with his Feet forward, his Armes may be so spread and extended that they may hinder the rest of the Body. And this is *Hippocrates* opinion in his Booke *De Octimestri Partu*: *The flexible parts of the Infant are no hindrance vnto him if he issue with his Head forward: but if he come with his Feet forward, then they stop the passage*. That this figure of the Head forward, is the most naturall and safe way for the Infant, *Pliny* confirmeth in the eighth Chapter of his seuenth Booke *De Naturali Historia*. *The old custome is (saith he) that dead Folke are carried to their Graues with their Feet forward, because death is contrarie to life*. As therefore a Man commeth into the World with his Head first, so being dead he must be carried out of the World with his Feet first.

Besides this, all other figures of the Birth are to be called *not Naturall*. Now there are diuers figures of the Birth *natura quoniam, not Naturall*, but three especiall; with their Feet forward, with the side first, or double; all which *Hippocrates* expresseth in his Books *De Morbis Mulierum* and *De Natura Pueri*. *It is dangerous when the Feet come forward, for in such a Birth oftentimes the Mother perisheth, or the Infant, or both together*. To deprecate or auert this danger, the ancient *Romanes* built Altars to the two *Carmenta*: the one of them was called *Postuerta*, the other *Prosa* of the right or wrong proceeding of the Birth. And such Births are commonly called *Agrippa*, as it were *Egre partus*. So *Agrippina* said her Sonne *Nero* came into the World with his Feet forward.

The third condition of a Naturall Birth is, that it be swift, easie and without any vehement *Symptomes*. I call that a lawfull or legitimate Birth which commeth in due time: and that illegitimate which hapneth before or after the due time. The eighth month Birth is illegitimate, because it preuenteth the ninth month or stayeth after the seuenth month: and this is the Nature of the Birth, these are all the differences thereof.

QUEST. XXX.

How many times there be of a Mans Birth, and what they are.

Aristotle. The times onely of mans birth vncertaine;

 *Aristotle* that Genius and Interpreter of Nature, as he hath in all things acquitted himselfe wondrous well; so herein also he hath written excellently, that whereas Nature hath appointed almost to all Creatures a determinate and certaine time for the bringing forth of their young; circumscribed and constant limits of their gestation: yet to Man she hath granted a larger and freer Patent for the time of his procreation and gestation. House-Doues doe euerie month bill and breed young: A Bitch whelps at foure months: A Mare foales the ninth: And an Elephant the second yeere: Onely Man hath diuers times wherein he is brought forth, the seuenth, eighth, ninth, tenth and eleuenth months. This Women doe all of them confesse, whom we ought to beleue, saith *Hippocrates* in his Booke *De Septimestri Partu*, because they are most skilfull in this kind of learning.

This

This also is confirmed by the authority of *Hippocrates*, *Aristotle*, *Plutarch*, *Galen* and *Aphrodisæus*; and beside by certaine laws of the Romanes. The seuenth month, is the first limit of a mans birth, and before seuen months, no Infant suruiue, albeit some Egyptians, the Poets of *Naxos*, and many Spaniards report that some haue bene borne alieue the sixth month.

The 7. month
the first time

The seuenth month birth, *Hippocrates* saith is vitall or doth suruiue, in his Booke *De Principijs*. The Infant borne the seuenth month is reasonably borne & liueth. He is reasonably borne because he wanteth nothing in the perfection of his parts; for in the two months following there is nothing added to the perfection of the parts, but vnto the perfection of his strength.

The 7. month
childe Vitall.
Hippocrates.

Aristotle in his 7. Booke *De Natura Animalium* affirmeth the same, as also *Aphrodisæus* in his Problemes. *Galen* in his Commentary vpon *Hippocrates* booke *de Septimestri partu* saith, that he hath seene many children borne the seuenth month suruiue and do well. The same in Honor of *Hippocrates* was concluded by the Roman Lawes, and standeth in force at this day euen among our selues.

Aristotle.
Galen.

Lawes of the
Romanes.

Pliny reporteth, that *Sempronius* and *Corbulo*, two Consular Romanes, were borne of their Mother *Vestilia* the seuenth month. I haue also credibly heard it reported, that that good old man Doctor *Turner* of *S. Ellins* now lately gone to heauen, was borne the seuenth month and preferued by some small sustenance till he was able to suck, which was about two months after he was borne. And if you obiekt *Hippocrates*, who in his booke *de Septimestri partu*, saith, that there be few seuenth-month children, and of those few many perish, and therefore *Aristotle* biddeth that they should be laide in wool and carefully swathed. I will giue you this answer, that there are many seuenth-month births, because there is a great latitude of the 7. month.

Pliny.

D. Turner.

Obiection.

Solution.

Those that are borne in the beginning of the seuenth month may indeed liue, but they are exceeding weake and do not recouer strength in forty dayes, and of these we must vnderstand that place of *Hippocrates*, for he saith they are borne after 182. dayes, and a part of a day, now 182. dayes do make but the beginning of the 7. month. But those that are borne in the end of the 7. month, that is, after 210. dayes are strong, and few of them perish. Of such he speaketh in his Booke *de Principijs*, where he saith, The 7. month-Infants are borne according to reason, & do liue because they accomplish three tenths of weekes, and every tenth fulfilleth 70. dayes.

The difference
of the 7. month
Infants.

Againe the 7. month Infant is either a Male or a Female; A male because he is sooner formed, mooued and perfected in the wombe, if he be borne the 7. month he suruiue. A Female because shee keepeth not that proportion which is required to the Conformation, Motion and Birth, if she be borne the 7. month she wil haue life, but not hold it long. This first rule we establish as a Law, that the 7. month childe is legitimate and vitall, and that this is the first limit of a mans birth. The bringing forth of a childe at 8. months is called, not an abortment, a birth, but yet it is neither a vital nor a legitimate birth. *Hippocrates* in his Booke *de Principijs*. No Infant borne the 8. month suruiue, and the same he repeateth in his Booke *de Octimestri partu*, and *de Alimento*, elegantly indeed, but very obscurely, where he saith, The birth of 240. dayes (such is the 8. month birth) is and is not. As if he should say, the Infant is indeed borne the 8. month, but so, that it had as good not haue bin borne, because it cannot suruiue.

The 8. month
Infant is not
Vitall.

In Egypt where that fruitfull *Nilus* runnes, and in *Spaine* where women haue easie trauels, and where the heauen and the earth agree together to be kinde to man, there many men say, that some 8. month Infants do liue. *Asclepiades* saith, that the women of *Naxos* doe bring forth their children alieue the 8. month, and they suruiue either because *Iuno Lucina* hath giuen them this priuiledge for *Bacchus* sake, or becaule *Bacchus* was borne that month, after whose name it is called *Dionysia Naxos*. But these are vaine things, and beside are different from the Vniuersall Nature as the Philosophers speake. Add hereto, that in the account of the months women are often deceiued, so that they seeme to themselves to bring forth the eight month when it is indeed the 9. for there are some whose courses flow the 2. month after their conception, and such women think they haue not conceived when indeed they haue conceyued.

In Egypt some
suruiue at 8.
months.

Aristotle in his 10. Booke *de historia Animalium* sheweth how there may many errors happen in the computation of the time of their conceptions. There are some (saith he) who thinke that there can be no conception vlesse both parents do at the same time eiaculate their seed. Now such are deceiued; because the body that is best disposed soonest looseth, wherefore that seed being very strong is not corrupted, but beeing drawne it is referued for that mixtion which is to be afterward.

How women
are deceiued in
the account of
their Con-
ceptions.

They erre also who thinke they haue not conceived vlesse the wombe be dry and all the seed be retained; because of the whol seed which proceedeth as wel frō the man as from the woman, the matrix draweth first no more then it can, then no more thē it should draw. Many

Many women
thinke they
haue concei-
ued when they
haue not.
The 9. month
birth is most
legitimate.
The 10. month
birth vitall.

women therefore haue conceiued which thinke they haue not conceiued, and these doe easily mistake the sixt for the seuenth, the eight for the ninth months.

The nine month birth is of all other the most vitall and legitimate, as that which is in the middle of the two extreames, and is beside most familiar to nature. Concerning the ten month birth *Hippocrates* hath written many things in his Books *de natura pueri*, & *de septimestri partu*. *Homer Odiss.* maketh *Neptune* to speak thus vnto the *Nimphe*. After a yere is accomplished thou shalt bring forth a beautifull burthen. That is to say, the tenth month, for of ten months consisted the yere among the *Aolians*, as also among the ancient Romanes, now *Homer* we know was an *Aolian*.

11. month
birth contro-
uersted.
How women
are deceiued in
their computa-
tion.

Concerning the eleuenth month birth there is great difference among authors; *Hippocrates* seemeth to haue conceiued diuersly of it; in his Book *de Natura pueri* he determineth that the tenth month is the longest limit of gestation, within ten months at the furthest saith he, the Infant is borne. But those women who thinke they go vnto the eleuenth month are deceiued in the number of dayes and computation of the time of their conception, for sometime the womb is distended with winde and breedeth a false conceit of their being with childe. Oftentimes vpon the suppression of their courses their bellies swell and they thinke they are conceiued, making their accompt from the time of that suppression.

Aristotle vnto
thankfull to
Hip. his good
maister.

Aristotle, who indeed tooke all that he writ concerning the Nature of Creatures only from *Hippocrates*, and yet (vngatefull man as he is, neuer maketh mention of him) reprooueth those women who say they haue borne their children eleuen and twelue months. The beginning saith he, of Conception most women are ignorant of, especially if they couple and conceiue when before their wombes are distended with winde; for then they esteeme that they haue conceiued when their bellies beginne to bee distended, whereas indeede they are first distended with winde and afterward conceiue: For *Hippocrates* determineth that the tenth month is the utmost limit of gestation; (and *Ulpianus* the Lawyer admitteth no children to the inheritance who were borne after the tenth month;) but in his Booke *de septimestri* and *octimestri partu*, he acknowledgeth the 11. month.

Hip reconciled
to himselfe.

You shall reconcile *Hippocrates* to himselfe, if you say, that the end of the tenth month is the absolute and longest limit of gestation, & that a woman cannot fulfil eleuen compleat months, but if she bring forth in the 11. month it is in the beginning thereof, and that is *Hippocrates* meaning when in his Book *de octimestri partu* he saith, that some women carry their burthens vntill the eleuenth month, he meaneth vnto the beginning of the 11. month.

Auicen of a
birth at 14.
months.

As for the twelfth, the thirteenth and the fourteenth months *Masurius* reporteth that *L. Papius* the Pretor awarded an inheritance of Land against an heyre whose mother confessed that she bore him after thirteene months; because the time of his birth seemeth to him to be litigious. *Auicen* writeth that he saw a childe borne fourteene months after Conception: but if any such thing happen, we conceiue it to be a rare accident and beyond the consideration of Art.

Auicen of a
birth at 14.
months.

We conclude therefore that the first limit of a mans birth is the seuenth month, the last is the 11. the intermediate times are the ninth and the tenth.

Auicen of a
birth at 14.
months.

Now what are 7. month, 8. month, nine month and ten month births, and of how many daies euery one of these consisteth, and also what account and supputation of dayes we are to make, it remaineth that we should declare, for vpon this Axle-tree is the whole Controversie rowled; this labyrinth hath innumerable windings and turnings, out of which no man shall be able to redeeme himselfe who is ignorant of *Hippocrates* computation of months, decades, weeks & dayes; wherefore we will a little while stay our reader vpon the consideration of them.

Mensis Solaris.
Mensis Lunaris.

A Month according to the Astrologians is manifold, one called *Solaris* another called *Lunaris*, a third Common, that is to say, according to the *Iulian* Kalender. That is called a Solary month wherein the Sunne runneth through thirty degrees of the Zodiacke, and it containeth perpetually thirty dayes. The Lunary month according to *Galen* is double, the one of *Progreffion* the other of *Apparition*. The month of *Progreffion* he calleth that space which commeth betweene one conjunction of the Moone with the Sunne and another, and it containeth nine and twenty dayes and a halfe. A month of *Apparition* consisteth onely of 27. dayes, because three dayes are subtracted wherein the Moone lurketh as it were and giueth not her light. The

Mensis Solaris.
Mensis Lunaris.

Common month or the month of the Kalender doth not alwayes consist of the same number of daies. For the month of February hath 28. dayes, Iune 30. Iuly 31. And this is the variety and difference of months. Now what is *Hippocrates* month is very difficult to determine, some doe thinke it to be the Lunary, and the Lunary of *Progreffion* onely. And this may bee warranted

Mensis Solaris.
Mensis Lunaris.

Mensis Solaris.
Mensis Lunaris.

ranted by the authority of *Hippocrates*: for in the beginning of his Booke *De Septimestri partu* he writeth, that two months consist of 59. daies, and that 5. months are accomplished of an 147. daies and a halfe. Now five times twenty nine, make an 145, whereto if you add 2. daies and a halfe, the summe will amount to 147. daies and a halfe; so that euery month shall containe nine and twenty daies and a halfe. *Galen* in his Computation of the Criticall daies and the daies of Gestation, accounteth according to the Lunary month, and in his Commentarie vpon *Hippocrates* Booke *de Septimestri partu* is of opinion that no Infant suruiueth after two hundred and foure daies.

We on the contrary do imagine that *Hippocrates* months are Solary consisting of 30. daies, as we gather by his owne computation. For in his Booke *de Principijs* he saith, that the 7. month birth hath three Denaries or *Decades* of weekes, and in euery *Decade* are 70. daies; and that 3. *Decades* of weekes make 210. daies.

If therefore the 7. month birth do accomplish 210. daies, then euery month shall containe 30 daies, because seuen times thirty makes two hundred and ten.

Againe, in the same Booke he writeth, that a perfect birth is not accomplished till nine months and ten daies, but nine times thirty makes 270. whereto if you add ten, the sum will amount to two hundred and eighty.

Moreover, in his Booke *De Alimento* he writeth, that the birth at two hundred and forty daies, (by which all men vnderstand the eight month birth) is and is not: now two hundred and forty daies make eight Solary months. Furthermore in the third Section of the second Booke *Epidemion*, Whatsoeuer is mooued within seuentie daies, is perfected within the triplication. Now three times seuentie make two hundred and ten, which accomplish seuen compleate months.

Finally and most manifestly in his Booke *de octimestri partu* he teacheth that we must make our computation of months in the gestation of the Infant by the Solary months consisting of thirty daies. The new Moone (saith he) is one day, and the thirtieth part of the month. Two daies make the fiftieth part of the month, and three daies a tenth; wherefore we conclude, that the months of the birth are Solary rather then Lunary. And truly the efficacy and power of the Sunne is more auailable to generation then that of the Moone, whence it is that *Aristotle* in the second of his *Physicks* calleth the Sun *Stellam Salutarem* and *verum*, that is, a healthfull and fruitfull Starre, because it is the parent and procreatrix of all things. For the Sun and a man do generate a man. As for the Decads and weeks of *Hippocrates*, there is no reason we should much trouble our selues about them, for they are as cleare as the midday-sun it selfe. Euery *Decade* containing seuentie daies, and euery weeke seuen.

One scruple there remaineth to be remooued, wherewith I confesse I was a great while puzzled, and that is, why the Computation of daies to make the seuenth month birth is not one and the same: for in his Booke *de Principijs* he saith, that the seuenth month birth is brought into the world the 210. day, which opinion of his, *Auicen* the Prince of the Arabians followeth, *Fen. 21. lib. 21. chap. 2.* of the generation of the Embryo. But in his Booke *de septimestri partu* and in the very beginning he saith, that the seuenth month birth is borne within an 182. daies, and a part of a day, which also he repeateth in his Booke *de octimestri partu*, where he saith, that the seuenth month birth is fulfilled in halfe a yeere and a part of a day, that is to say, in a 182. daies and fiftene houres.

Some of the Interpreters, that they might auoide these snares, haue disallowed of his booke *De Septimestri Partu*, as if it were not *Hippocrates* owne, at least they boldly affirme that this place is corrupted. But we on the other side are as confident that it is truly Hippocraticall. For not onely *Galen* Commented vpon it, a few fragments of whose labour remaine to this day, but also the Lawyers of that time when Learning did most flourish at Rome and Athens, did translate this very sentence according as wee at this day read it into the number of their Sanctions. Wherefore these diuers not contrary places concerning the number of daies we will thus reconcile.

The Latitude of the seuenth month is very great, neither is the seuenth month birth alwayes brought into the world in one and the same day. There is a seuenth month beginning, and a seuenth month perfected. The beginning consisteth of an hundred and eighty daies & a part; the perfection consisteth of two hundred and ten daies. Before an hundred eighty two daies no Infant suruiueth, so that this is the first limit of the seuenth month. After two hundred & ten daies it is no more called a seuenth month but an eight month birth. The first births in the beginning of the seuenth month are indeede vitall, yet very languid and weak: the latter are

We thinke
Hip. month to
be Solary, con-
sisting of 30.
daies. Autho-
rities to proue
it.

How diuerse
Hip. is in com-
putation of
daies.

That Hip.

partu* is legiti-
mate.

Hip. interpre-
ted.

The utmost
time of the 7.
month birth.

very strong. Wherefore *Hippocrates* in the places before quoted expressed only the two extreme times of the seventh month birth, that is to say, the first and the last. The middle times he maketh no mention of, as of 204. dayes, &c. because they are sufficiently knowne by the nature of that extreme vnto which they approach the nearest. And this is not my interpretation of *Hippocrates*, but *Hippocrates* own. For, as in his Book *de Octimestri partu* he calleth those *Decimestres* not onely who accomplish ten whole months, but also that reach a few dayes within the tenth month: So those are called *Septimestres*, who beside six full months do attaine some dayes of the seventh. And yet more plainly in his Book *de Alimento* after hee hath described the *Septimestres*, *Octimestres*, *Nonimestres*, and *Decimestres parius*; at length he breaketh out into these words, *In these months are begotten or rather breeded more and fewer according vnto the whole and the parts*, that is, either in a part of the month, or in the whole & full month. And in his Booke *de Septimestri partu* he saith, that the five months which come betweene the first and the seventh must be numbred whole: but the first and the seventh it skilleth not much though they be imperfect.

The interme-
diate daies and
months are
onely perfect.

So in the computation of the Criticall dayes, those dayes which go before the *Crisis* must bee accounted whole; but the Criticall day it selfe wherein Nature endeauoureth the *Crisis* hath a great latitude; for a *Crisis* yea a happy and prosperous one, may fall out in the beginning, in the midst, or in the end of the seventh or the fourteenth dayes: wherefore those months which go before the birth, must bee all accounted wholl excepting the first. Againe the very month of the birth which is of the same nature for accompt with the Criticall day, hath two extremes and many intermediate times. In any of which if the Infant be borne hee may suruiue. And thus I thinke you may cleare your selfe out of the Thorne and intricate passages of months and dayes in the computation of the legitimate or illegitimate times of the birth.

QUEST. XXXI.

What are the vniuersall and particular Causes of the Birth.

Democritus.
The Sceptikes

Aristotle.

Hippocrates.

Heraclitus.

The vniuersall
causes of the
birth.

On the part of
the Infant.

Why the mola
& many mon-
sters live long
in the wombe.

Democritus a great Philosopher of his time, complaineth that the truth is drowned in a deepe well. The *Pyrron* or Scepticke Philosophers thinke that all things are vncertaine and that nothing can be determinately knowne. *Aristotle* the Father of the Schoole of Philosophers saith, that the certaine and Naturall causes of all things naturall are onely knowne to Philosophers; which before Philosophy it selfe was borne our admired master *Hippocrates*, in his Book *de Aëre, aquis & locis* hath thus expressed, *ἐν δὲ τῷ φύσει οὐδὲν γίνεται, οὐδὲν δὲ φύσει γίνεται, οὐδὲν δὲ φύσει γίνεται*, Nothing in Nature is done without Nature, that is, without a naturall cause. These causes if any man with *Heraclitus* shall deny, hee shall not onely entangle himselfe in a thousand Labyrinths of absurdities, but also forfeite all knowledge and assured demonstration; for to know, saith the Philosopher, is to vnderstand the causes of things; Seeing therefore the birth is a naturall action, and that the times thereof are very different, it shal not be amisse a little in this place to enlarge our selues in the disquisition of the causes thereof.

The Causes therefore of the birth are some of them vniuersall, others particular. The vniuersall causes are common not onely to man but also to all creatures; and some of them are on the part of the birth; others of the part of the Matrix or wombe; because the birth proceedeth from an equall contention of the birth, and the bearer. The cause on the part of the birth *Hippocrates* in his Book *de Natura pueri*, elegantly expresseth to be the defect of both sorts of aliment: Spirituous and Solid on this manner; *When the Infant becommeth larger and stronger, the Mother cannot supply it with fit and sufficient Aliment, which while it seeketh, with often kicking it breaketh the Membranes, and being vnloosed from those bandes yssueth forth.*

The Mola or moone calfe may be carried in the wombe many yeeres, because it is neyther nourished nor doth transpire; wherefore desiring neither aliment nor ayre, it is still retayned. There are ingendred oftentimes in the wombs of women, Monsters and Creatures of diuers kinds, as Serpens and Mould-warps, which because they haue litle bloud haue also litle heate, and being contented with transpiration alone doe lurke many yeeres in the corners of the wombe, neither would euer issue of their own accord vnlesse they were driven forth either by the contention of the womb or by the helpe of the Physician. The want therefore of nourishment is the first cause of the birth.

There

There is also another vniuersal cause on the part of the wombe: for the wombe hauing a determinate quantity and magnitude beyond which it cannot be extended, when once vpon the increase of the Infant it is come to that extent, it labourerth to lay downe the burthen whereby it is oppressed: and according hereto *Hippocrates* saith in his 1. Booke *de morbis mulierum* that abortments do happen when the wombe is too little, that is, when the Infant is so increased that it can be no longer contained in the wombe. *The wombe* saith he *hath peculiar dispositions, bred with it which cause abortment*, and among those dispositions hee accounteth the narrownesse thereof: wherefore the Infant seeking nourishment and the wombe not admitting further distention, do make the birth.

The vniuersal
cause of the
birth on the
part of the
wombe.
Hippocrates.

The particular causes doe belong onely to the birth of a man, because man onely among all creatures hath the times and spaces of gestation and birth very diuerse and different, of which differences the causes also are as different. First it is manifest that all brute beasts are at certaine times prouoked to Generation: as therefore the times of their coition are certaine: so also are the times wherein they bring forth; mankinde because at all times and seasons he is fitte for Generation, doeth at all seasons also bring forth his burthen.

The particular
causes of the
birth.

Now the limits of gestation and birth of the Infant are manifold and diuers; not on the part of the vniuersal agent, that is of Nature; for the power of Nature is the same in man and in beasts; the motion one and one established Law: but the variety comes from the diuersity of matter, which in a man vndergoeth manifold alterations more then in a beast; for brute beasts vse alwayes the same simple dyet, a man doth not onely vary in the matter but in the times of his repast. The other creatures after they haue conceived will no more admit the Male, which is not so with a womā, whence comes no smal alteration in the body of the Infant. The other creatures are not transported with passions, which how hurtfull they are vnto men, euery man hath too much experience in himselfe and *Plato* in *Charmide* elegantly recorded, writing, That all the mischiefes that happen to mens bodies proceed from the affections of the mind.

The diuersitie
is from the
matter.

The 1. cause.

The second

The third
Plato.

Some there are who referre the causes of the variety of the birth to the different Nature of the seed, some ripening sooner some later. To these we wil add the singular prouidence of nature for the conseruation of mankinde, which is the Finall cause: For being more carefull of man (whom *Pliny* calleth Natures darling) then of the brute beasts, she hath granted vnto him more times and limits, both of gestation and birth. The times of birth are the 7, 8, 9, 10, & 11. months: but why the 7. and 9. months are vitall, that is, why children suruiue who are borne in those months and not in the 8. this indeed is hard to be knowen.

The fourth.

The fifth.

Why the Infants
suruiue at 7.
months and
not at 8.
The opinion
of the *Pythagorians*.

The *Pythagorians*, *Geometricians*, *Astrologians*, & *Physitians* are of diuerse minds concerning this matter, and because it is an elegant controuersy and full of variety we will take liberty in this place to discusse them all.

The *Pythagorians* and *Arithmeticians* referre all things to number; for they make & ordaine a threefold order in things; of formes, figures, & numbers, among which, numbers are the chiefe: for in the whole Scripture we reade that all things are disposed in number, waight & measure.

Of Numbers some are equall some are vnequall; the equall numbers they call foeminine, the vnequall masculine; the first imperfect, diuisible and vnfruitfull; the latter perfect, fruitfull and indiuisible; and therefore say they these numbers haue the nature of a principle; for the equall number is generated of 2. vnequals; but an equall neuer generateth an vnequall. Furthermore among the vnequall numbers, the 7. hath the first place, whose maiesty and diuinity is so great, that the ancients tearmed it sacred and venerable. The *Magi* of the *Indians* and the wise Priests of the *Egyptians* called the 7. the number of the greater and the lesser world.

Differences of
Numbers.

The excellen-
cy of the num-
ber of 7.

Philo the Iew in his Booke *de mundi opificio* attributeth this prerogative to the 7. that it alone can neither generate nor be generated: of other numbers which are within 10. some doe generate but are not generated, as the number of one or the vnity; some are begotten but doe not beget, as the number of eight; some both beget and are begotten as the number of 4. onely 7. neither begetteth nor is begotten, and hence commeth the perfection and dignity thereof; for whatsoeuer neither begetteth nor is begotten that remaineth vnmoueable. Againe, the *Pythagorians* call the septenary number the rye or knotte of mans life, which *Tully* in *Scipio* his dreame acknowledgeth, where he saith, *That the 7. is the knot of all things.*

Harmonie

There is also in this number most harmony, as being the fountain of a pleasant *Diagramma*, because it containeth all the harmonies, *Diatessaron*, *Diapente*, *Diapason*; as also all proportions *Arithmetical*, *Geometrical* and *Musical*.

The Diuines call it the number of Perfection, because all things were perfected the 7. day. The number of Rest, because the 7. God rested from all his works. The number of Sanctification,

What the di-
uines say of the
number seuen.

tion, because it was commaunded to be sanctified or kept holy. Finally, the number of *Reuenge*, of *Repentance* and of *Beatitude*: whence it was that the Poet saith, *ô terque, quaterque Beati*, *O thrice and foure times happy*, i. seuen times happy.

Philo Iudæus and *Linus* an old Poet haue written many things in the commendation of this number of seuen. To omit that which some haue obserued, that there are seuen wonders of the world, 7. wise men among the ancients, seuen greater & lesser Triones in heauen, 7. circles wherewith the heauens is ingirt, seuen wandring starres or planets, seuen starres in the Beare, seuen starres of the *Pleiades*, seuen changes of the voyce, seuen physicall and naturall motions, seuen vowels among the Greekes, seuen ages; that the seuenth age shall be a golden age, seuen mouths of *Nilus*, seuen mettals, seuen liberall Arts, seuen windows in the head, seuen causes of all humane actions, seuen Cities that stroue for *Homer*, that the seuenth Sonne is able to cure the Kings Euill, and a seuenth Daughter if shee bee present quickneth a womans trauell, the hearbe Tormentil which hath 7. leaues resisteth all poysons. All these things I say we wittingly and willingly passe ouer, for it must be confessed that vnder the name of numbers there are many triuolous and superstitious toyes thrust vpon the world: I come to Philosophicall and Physicall demonstrations.

It is to be marked that the Physitians and Philosophers haue obserued how our life is dispensed by seuens.

The life of mā consisteth of seuens.

Hippocrates in his Booke *de principijs*, saith that the age of Man consisteth of the septenary number of daies: For many of them who in seuen dayes space doe neuer eate nor drinke, doe dye one of these dayes, aswell because the Gut called *Ieiunum* is contracted, as also because the stomacke in so long cessation of his office becommeth forgetfull afterward to do his duty.

The Seed of the man which within seuen houres after eiaculation returneth not backe, wee may bouldly pronounce is Conceiued: so the seuenth day after Conception, the first rudiments of all the spermatical parts doe appeare, and the geniture saith *Hippocrates*, *hath the seuenth day whatsoeuer the body ought to haue.*

The seuenth-month births are vitall not the eight, and the seuenth day after the birth the Infant casts the remainder of his Nauell: after twice seuen dayes he beginnes to mooue his eyes towards the light, after seuen times seuen he is able to mooue his head and eies euery way. The seuenth month he begins to breede his teeth, after twice seuen he is able to sit without feare of falling, after thrice seuen he begins to speake, after foure times seuen to goe, and after fife times seuen to leaue sucking.

The seuenth yeere he changeth his teeth, their third Generation beeing then made of most solid aliments as *Hippocrates* writeth in his Booke *de principijs*; at that time also his speech grows perfect, whence the Grecians doe make seuen vowelles. After twice seuen yeeres the signes of youth begin to breake out, in maidens the courses flow, breastes swell, and they are fitte for husbands. In men the voyce changeth, and they grow petulant by reason of the vigour of their naturall heate. After thrice seuen yeeres they grow towards their strength which remayneth constant the fourth, fift and the sixt seuens, and that age is called *virilis* and *constans ætas*, that is *Manhood*. The seuenth septenary is called *quadratus*, because then a man is euery way accomplished both in body and in mind.

Augustus Caesar to Caius.

The ninth is esteemed Climactericall and very dangerous, for it hath beene alwayes obserued (as *Aulus Gellius* noteth) that this time of a mans life is for the most part accompanied with some notable danger of the life, or griefe of the mind. And therefore we reade in the same Author, that *Augustus Caesar* congratulath his Nephew *Caius* concerning this Climactericall yeere on this manner. *All haile my pleasant Nephew Caius, whom belecue me, I do alwayes desire when thou art absent from me, but especially at such times as these my eyes do euen faile with looking for my Caius, yet wheresoeuer thou art this day. I hope that with good health and good chere thou dost celebrate this my 64. birth-day. For as thou seest we haue overcome the 63. yeere, the common Climactericall and dangerous yeere for old men.*

Psal. 90. 10.

The tenth Septenary which fulfilleth the seuentieth yere, is esteemed to be the limit of life, and so the Kingly Propheth singeth in the Psalme, *The dayes of a man are seuenti yeeres, beyond which all is labour and sorrow.* Wherefore all Septenary dayes and months and yeeres are especially to be considered, because in them there happen notable mutations.

Hence it is that *Ficinus* the Platonist giueth him Counsell that desireth to prolong his life, euery seuenth yeere to take counsell of an Astrologian and a Physitian of the Astrologian, that he may vnderstand what dangers and where do hang ouer his head; and of a Physitian, that

that by a prescript rule of dyet he may auoide the threatnings of the Starres & their maleficall influence.

Aristotle in his 7. Book *de historia Animalium* doth also acknowledge this prerogative of the number of seuen, because in euery septenary the greatest changes do vse to happen. *Galen* deli-nering the precepts of health, maketh the distinction of Ages according to seuens. It is not therefore without good warrant, that the *Pythagorians* call the septenary number the beginning or principle of all things: *Tully* the tie or knot of all things; and Physitians warranted by cer-taine experience, the King or Prince of the Decretory or Criticall daies. Wherefore the Py-thagorians and Arithmeticians doe therefrom conclude, that the 7. month birth is vitall be-cause it consisteth of an vnequall and most perfect number.

Pythagoras
and *Tully*.

And this *Hippocrates* in his Book *de Principijs* doth also acknowledge, for therefore he think-eth that Infants borne the 7. month do suruiue, because they haue attained a iust and full num-ber of seuens. And that the 8. month birth is not vitall, because it hath not fulfilled the ful De-cades of weeks. Moreouer in his Book *de Septi. partu* he writeth, that the conceptions, Abort-ments and Births of Infants are *Iudged*, as we speake, in the same times in which diseases haue their *iudgement or Crisis*. Now wee know that all diseases are most what *iudged* on vnequall daies, and that the septenary number is onely truly Criticall.

Hippocrates ~~ack-~~
knowledgeth
the power of
the septenary
number.

If it be objected, that the 10. month although it be equall and foeminine is yet for the birth vitall and legitimate, the *Pythagorians* will make answer, that ten is the perfection of all num-bers and containeth in it selfe all numbers of perfection. And this is the opinion of the Pytha-gorians and Arithmeticians of the causes of the 7. month and 8. months births, who conceite that all things are to be referred vnto the force of numbers.

That the 10.
number is
perfect.

For my own part I thinke with *Aristotle* in his *Metaphysicks*, that Number of it selfe hath no operative power, for so it is a quantity; but the nature of Number as it is the forme of time co-cluding all the works of Nature hath a strong efficacy. And this Nature & necessity as it were of Nature it selfe, *Hippocrates* in the end of his Book *de Principijs* promisseth to explaine.

What wee
thinke of
Numbers.

The Astrologians and Figure-flingers do referre the causes of the 7. month, 8. month, and 9. month births to the diuerse aspects of the Planets, for ouer euery month they think each planet hath predominance. *Saturne* ouer the first, who with his coldnes and drought reteyneth the li-iquid and moyst seed, and congeleth it as it were into a conception. Ouer the second *Iupiter*, who by his warmth and vitall heat causeth it to increase. Ouer the third *Mars*, who with his heate and drought maketh the members beginne to mooue. Ouer the fourth the *Sun*, who by the power of his wonderfull heate enlargeth all the passages. Ouer the fift *Venus*, who addeth grace & beauty to the Infant. Ouer the sixt *Mercury*, who polisheth and absolueth the Organs of motion. Ouer the 7. the *Moone*, who filleth the empty spaces and distances of the Fibres with flesh and fat, & with her moysture relaxeth the orifice of the womb that the birth may be easy. If therefore the Infant do the 7. month yssue furnished with all these endowments of the Planets, then is he vital and is likely to suruiue; but if being weak he be not able to loosen him-selfe from the sides of the wombe, then *Saturne* that maleficall Planet and aduersary to the principles of our life, returneth againe vpon him and so like a Tyrant holdeth the Infant priso-ner; or if in that month he come into the world he presently perisheth, as hauing his vitall heate nipped by the cold of that churlish Planet. Adde heere to, that the weake Infant is not able to beare or endure so sudden an alteration fro the *Moone* to *Saturne*, as if it were from the lowest staffe to the Ladder, because all sudden mutations are enemies to Nature.

The opinion
of the Astro-
logians,
Saturne,
Iupiter.

Mars,
Sol,
Venus,
Mercury,
Luna.

But if he overcome the eight month, then to *Saturne* succedeth *Iupiter* that beneficall Pla-net, by whose prosperous and healthfull aspect all the ill disposition that came by *Saturne* is frustrated and auoyded; wherefore the ninth month the Infant is borne vital and liuely, as also the tenth and the eleventh, because of the familiarity of *Mars* and *Sol* with the principles of our life. And this is the opinion of the Astrologers concerning the Causes of our birth, which is indeed elegant and maketh a faire shew, but is in the meane time full of Error as *Picus Miran-dula* hath proued in a Booke which he hath written against Astrologers. For how may it be, that *Saturne* should alwayes beare sway the 1. and 8. months, when as women may Conceive in any months of the yere, any day in the month or any houre in the day? Why do Hindes calue the eight month and their yong suruiue, as *Aristotle* writeth in his 6. Booke *De Natura Animalium*? *Pliny* is of opinion in the 5. chapter of his 7. Book *de Naturali Historia*: That only those children are vitall if they be borne the 7. month, who were conceived the day before or after the Full of the *Moone*, or in the New *Moone*. But all these are idle and addele imaginations of wanton braines.

The opinion
of the Astro-
logians con-
futed.

Pliny his idle
opinion.

The

The Geome-
tricians pro-
portions.

The Geometricians referre the Causes of the birth vnto the proportion of the Conforma-
tion and motion of the Infant. For (say they) there is a double proportion of the conformation
to the motion, and a trebble proportion of the motion to the birth, which proportion if the
Infant hold, then shall he attaine alie and liuely into the world. So the 7. month birth is vitall,
because it is formed the five and thirtieth, mooued the seuentieth, and borne the two hundred
and tenth day.

Hip. authority.

And this opinion may be confirmed by the authority of Hippocrates, for in the third section
of his 2. Book *Epidemion* he saith: *What soeuer is mooued in the seuenth day is perfected in the tri-
plicitie.* But Auicenna confuteth this opinion. For if onely the proportion betwixt the conforma-
tion and the motion of the Infant were the cause that he suruiued, then should he aswel suruiue

Auicenna.

the 8. as the 7. month, because they keepe the same proportion. For instance, Say that an In-
fant be formed the fortieth day, then shall he mooue the eightieth, and be borne the 240. And
in this birth the proportion is exquisitely held, because twice forty make eighty, & thrice eighty
two hundred and forty dayes. Now Hippocrates in his Booke *de Alimento* saith, that an Infant
borne at 240. daies (which all men vnderstand to be the eight-month birth) is and is not. But

Hip. explained.

the authority of Hippocrates may well stand with this opinion, for it is not his meaning that
this proportion is the cause of the life of the Infant, but simply & absolutely he saith, that there
is a certaine proportion betwixt the conformation, motion and Birth of the Infant, which no
man will deny.

The 5. opinion
of the Philo-
sophers and
Physicians.
The Lawes
of Nature are
certaine.

It remaineth now, that we acquaint you with the Philosophers and Physicians reasons why
the seuenth-month birth is vitall and not the eight. Nature although she be illiterate and vn-
taught, yet hath she constant Lawes which her selfe hath imposed vpon her selfe, definite also
and limited motions which she alwayes keepeth without inconstancy or mutability, vnlesse
she be hindred by some internall or externall principle. As therefore she neuer endeauoureth
any perfect Criticall euacuation vnlesse the humor bee before concocted and prepared:
So she neuer undertaketh a Legitimate birth till the Infant be perfected and absolued in all his
numbers. And as in crudity no good Crisis is to be hoped for according to Hippocrates: so be-
fore the Infant be perfected, the birth cannot be legitimate or vitall. For the birth saith Galen is
a kind of Crisis. Now before the seuenth-month the Infant is not perfected, and therefore be-
fore the seuenth month he cannot be borne a liue. But the seuenth month if hee bee strong he
breaketh the Membranes, maketh way for himselfe and suruiue because he is perfect, espe-
cially if it be a male child.

No vitall birth
before perfe-
ction.

The 8. month
birth why not
vitall.
Reason.

The eight-month although he be perfect he cannot suruiue, because he is not able to beare
two afflictions, one immediately succeeding in the necke of another. For in the seuenth
month hee laboureth sore, and repeateth his contention the eight, before his strength is resti-
shed.

Hippocrates
authority.

And this is Hippocrates opinion in the very beginning of his Book *de Olfimestri partu*, Con-
cerning the eight-month birth I am of this Iudgement, that it is impossible that the Infant should
beare two succeeding afflictions, and therefore those Infants doe not suruiue. For they are twice af-
flicted, because to the euils they suffered in the wombe the 7. months are added also the payne
in the birth the eight month.

Reason.

Again the 8. month birth is not vital, because it cometh after the birth day, which should
haue bene the 7. month, and before the birth day which is to be the 9. month. Whence wee
may gather that some ill accident hath betided the Infant or the mother which hindred the
birth the 7. month and preuented the ninth.

And hitherto belongeth that golden sentence of our admired master Hippocrates in the 8.
Section of his 6. Book *Epidemion*. *If nothing happen within the prescript time of the birth, what-
soeuer is borne shall suruiue.*

Why a wo-
man goeth not
about 11.
months.

But now why a woman doth not beare her burthen beyond the 10. and the 11. months,
Hippocrates in his Book *de Natur. pueri* referreth the cause to the want of Aliment. Now the
Aliment faileth as well because a great part of the blood flowes back vnto the Pappes for the
generation of Milke, as also because the Infant is nourished only with pure and sweete blood
which the mother can no longer in sufficient quantity supply vnto him. Neither is that to bee
passed ouer with silence which Hippocrates obserued in the Book before named, to wit, that in
some women the Aliment faileth sooner, in some later. Those which are not accustomed to
bring forth, haue lesse Aliment then others for their Infants, because the blood is not accust-
omed to turne his course toward the womb. Again, those women who haue lesse store of their
courses and of Milke, their Aliment faileth the soonest.

What women
defraud their
Infants soonest

It is also worth our obseruation that large and great creatures do carry their burthens the longest, because they doe not so soone attaine the perfection of their increment or growth: So an Elephant bringeth not forth before the second yeere after her conception, but house-doues breed euery month.

Why great creatures carry their yong long.

Man being of all Creatures the most perfect, the most wise, the most temperate and as it were the measure of all others, hath also moderate times of gestation, that is, the 7. and the 9. months if Nature be not interrupted or preuented.

QUEST. XXXII.

Whether in a desperate birth the *Cesarian* Section be to be attempted.

Aristotle in his 7. Booke *de Natura Animalium*, sayth that among all Creatures a Womans trauell is most laborious and difficult, as well because she leadeth a soft and sedentary life, as for that a mans Braine is the largest and so his head great especially, as long as he is in his mothers wombe; now the head vseth to come forward in the birth. This birth as saith *Galen* in the eight Chapter of his fifteenth Booke *De usu partium*, exceedeth all admiration, for the mouth or orifice of the womb, which all the time of the gestation is so closed that a needles point cannot passe into it; in the birth is so enlarged that the Infant yssueth out thereat.

Why the birth of man is most difficult.

A miracle of Nature in the birth.

But there are many obstacles which intercept the passage of the Infant by the orifice and necke of the wombe, as the thicknesse and magnitude of the Infant, or natural straitnesse of the inward orifice and of the neck; a distortion, inflammation, some tumor against nature, a fleshie Caruncle, a scarre, or the faulty conformation of the share-bones. For oftentimes in the inner part of the share-bone there is a sharp proesse which intercludeth the passage of the Infant vnto the birth place, and then there is no hope that the woman can be deliuered: Wherefore either the Infant must perish or the mother, or both together. In this so hard and desperate an extremity, the question is what may be attempted? we answer. If the mother bee dead and the child yet liuing, then presently without any delay the wombe of the mother must be ript open. And those children that are thus taken forth are called *Cesares*, or *Casones* from the cutting of the mothers wombe, from whence the *Cesars* had their names. After this manner as *Pliny* reporteth in the 9. Chapter of the 7. Book of his Naturall History, was *Scipio Africanus* the elder, *Julius Cesar* and *Manilius* borne.

What things hinder the outgate of the Infant.

The wombe must be presently opened if the mother be dead.

But if the mother be yet aliue, and the Infant by no other meanes can safely bee brought forth, the same section or opening of the wombe may be administred; for common experience and the authority of ancient Physitians doe assure vs that the wounds of the muscles of the lower belly and of the *Peritonaeum* or rim are not mortall.

Though the mother liue, yet this section may be attempted.

Hippocrates in the 3. Section of his 6. Book *Epidemion*, commaundeth vs to cutte our Dropsy patients instantly: now this Section for the Dropsy is a wounding of the *Epigastrium* or lower belly & the *Peritonaeum*; as for the womb it selfe *Paulus Aegineta* teacheth vs that the wounds thereof are not mortall. It appeareth vnto vs, saith he, that though the whole *Matrix* bee taken away, the woman will ordinarily suruiue.

Hippocrates *Paulus*.

Concerning this *Cesarian* section, *Franciscus Rossetus* the French Kings Physitian hath set forth an elegant Booke so beautified with Histories and abounding with good arguments, that we should abuse our time and your patience to transcribe them in this place: wherefore we remitte those who desire further satisfaction heerein to the learned Author.

Franciscus Rosset.

QUEST. XXXIII.

Whether in the Birth the Share and Haunch-bones doe part asunder.

He works of Nature in the conformation, life and nourishment of the Infant are indeede full of admiration, but her last endeuour in the birth thereof is indeed the crowne of all the rest, as that which exceedeth all admiration. For the orifice of the wombe which after the first apprehension and conception of the seed was so exquisitely closed that it wil not admit the point of a Probe: now that the Infant

The wonderfull indeuour of nature in the birth.

fant with turning, kicking and breaking of the membranes prepareth toward his enlargement, it is so relaxed as if it were a gate wide open.

But because Nature is so wise and provident that she undertaketh nothing without due preparation, therefore in the last months of gestation shee lyneth the inner surface of the orifice with a slimy and mucous humor, which thereupon becomming moyst and soft doth more easily distend or enlarge it selfe without feare of laceration or tearing.

Now whereas the wombe is contained within the capacity of the hanch-bones, & is walled about on the fore-side with the share-bones, on the backe-side with the holy and rump-bones, and on either side with the hanches, whereof some are ioyned together with a fast and immovable articulation, other by the mediation of a cartilage or gristle: whether in the birth there be a divulsion or separation of these bones, that now is the question we have in hand.

That the bones
are parted in
the birth.
Authorities.
Hippocrates,
Auicenn.

Some learned men are of opinion that the share-bones and the haunch-bones are seuered, which also may bee confirmed by the authorities of many right learned men and by reasons which carry with them a faire shew of truth. *Hippocrates* in the end of his Booke *de Natura pueri* wrote on this manner. *In the very birth the whole body is as it were vpon the racke, but especially the loynes and the hanches, for their Coxendices are distracted & parted asunder.* And *Auicenn* in his 3. Booke, *Fen. 2. 1. Tractat. 1. Cap. 2.* saith. *When the Infant is borne the wombe is opened with such an apertion as cannot bee made in any other place, and it is necessary that some iunctures must be separated, which are so sustained by the helpe of God so disposing and preparing, and afterward doe returne to their naturall continuation; and this action of all the works of Nature is the strongest and most forcible.* *Rabbi Zoar* vpon the 1. of Exodus. *Thou shalt not easily find any thing in the whole administration of Nature more to be admired then that distraction of the share-bones in womens trauell, which indeed is done by the providence of God to whom Nature is but a seruicable hand-maid, for otherwise no strength almost is able to separate them. The like also we see in the shooting of Stags hornes which euery yeere fall and grow againe.*

Rab. Zoar.

Pinaus opinio.
His first rea-
son.

Seuerinus Pinaus in his Physiologicall and Anatomical work is of the same opinion, which also he strengtheneth by some reasons. Before the 7. month, saith he, the womb & with it the Infant doth alwaies ascend; after the 7. month he descendeth and prepareth himselfe toward his enlargement. At that time the priuities of the woman with childe are moystned with a mucous slime, and the parts are dilated and relaxed, with which humour also by degrees the gristles of the share-bones are inebriated, that in the birth they might be the more laxe. Furthermore almost al the gristles of the body in progresse of time doe dry into a bony substance as may be seene in the chinne; but the cartilage which tyeth together the share-bones remaineth gristly to the end of our life, neither euer becommeth bony because in the birth it is to be distended and enlarged. Moreouer if you well consider virgins of 16. or 18. yeeres old, and againe take notice of them after they haue conceiued, thou shalt perceiue that their hanches are distended, their *Hypogastrium* enlarged and their buttockes become broader, especially when they are neere the time of their deliuerance: and therefore it followeth that those parts are dilated. Moreouer, those who haue liued long virgins haue harder trauels then yonger wenches, because their gristles in these places are more dried and lesse relaxed.

The second

The third

The fourth

The fifth.

A story.

Finally, such as neuer haue conceiued haue thinner gristles, and such as haue ofteneft conceiued haue them most thicke and are broadest in the hanches. Wherefore in the birth the share-bones are parted asunder one from another, and the hanch-bones from the *Os sacrum* or holy bone. And for the confirmation of this opinion, he telleth a Story of a woman who was new deliuered and shortly hanged, whose share-bones were so distracted that one of the *Coxa* was lifted vp and the other depressed.

Our opinion
that the bones
cannot be se-
uered.

For my owne part that I may freely speake what I thinke, I do not think that these bones in the birth can be vnioined, for they are so fast knit together that no violence can seuer them. And if they bee separated asunder how shall they be againe coupled? with what Cement or Glue shall they be vnited? For a new Synchondrosis or articulation by the mediation of a cartilage cannot be made. If you say with *Hippocrates* that they chinke a little, I will not be against it. Also that the gristly end of the holy-bone, which they call *Coccyx* or the rumpe, may bee torally retracted and so giue way to the Infant that there should bee a greater space left for his out-gate, that I can well beleue. As for *Pinaus* arguments they may thus be in order answered. It is indeed said and said truly, that in the last months of Gestation the inner orifice of the wombe is lined with a slimy humor, proceeding eyther from the vrine vessels, or from the humours sweating through the Membranes, or otherwise from the reliques of the Infant; but that humor say wee cannot attaine vnto the Share-bones or to the Cartilages betweene them,

*Pinaus argu-
ments answe-
red.*
To the first.

them, neither yet vnto the hanch-bones; because the wombe doth not immediately touch the share-bones; for betwixt the wombe and the bones lyeth the bladder lurking betwene the two coates of the *Peritonaeum*, and compassed round about with the *Peritonaeum* as it were with a purse or Satchell.

And whereas he saith, that the Cartilage which knitteth together the share-bones neuer becometh bony but alwayes remaineth gristly that it might be relaxed in the birth; it is but a slight reason; for neither in men is that gristle euer found to be bony. In young wenches after they haue conceiued, their hanches are distended and the capacity becometh larger, and that because at that time all the parts of their bodies do grow and the heate which before was well neere choaked with the aboundance of humors beginneth to shine forth and gather strength. Elder Maidens hauing conceiued haue harder trauelles then yonger, not because the gristles are drier but because their wombs are drier; for those that vse to conceiue and beare children haue moister wombes, larger vessels and all the capacities more large and ample, and therefore their trauell is more easy. One History doth nothing moue vs, for we haue seene many who haue perished in the very brunt of their trauell in whom there hath appeareth no such matter, and we obserue that women in their trauels do more complaine of the paine of their *Os sacrum* and rump, then of the region of the share-bones.

And thus are we come to an end of our long Discourse of the History of the Infant and the Controuersies thereto belonging, wherein how we haue acquitted our selues it resteth in thee gentle Reader to iudge; this one thing we know, that we haue wrought out our way through many difficulties, which if they shall prooue as profitable and pleasant vnto thee as they haue beene to vs difficult to ouercome, we haue abundant recompence.

Now wee proceede in our entended iourney to the Chest, wherein what Admirable rarieties Nature hath bestowed, wee referre thee to our Discourse to be satisfied.

The end of the Controuersies of the Fifth Booke.

Of the Middle Region, called the Chest or the Thorax, which conteyneth the Vitall parts, to which also we will referre the Necke with the Weazon.

THE SIXTH BOOKE.

The Preface.

HAving thus absolued the Lower Region with the parts thereof as well Nutritiue as Generative, together with the History of the Infant; it followeth that we ascend by the staires of the ridge to the middle Belly, wherein as in a curious Cabinet Nature hath locked vp the vitall Instruments and wheelles whereby the Watch of our life is perpetually mooued from the first houre to the last minute, by so iust a counterpoise as no Art of man could euer attaine vnto, albeit some rare Engineers haue gone very farre in imitation thereof. If we should enter into the causes of this perpetual motion, as it would be very hard to find them out, so would it spend much time to enquire after them. The highest cause is the hand of God, who hath prepared the Pullies, hung on the weights, and gouernes and winds vp the Chime at his own good pleasure. For if the Philosopher were not able (though he were nere of counsel to Nature) to discern with the sharp edge of his incomparable capacity the reason of the reciprocal cbbing and flowing of the Sea: how shall we be able to yeelde a reason of the Dilatation and Contraction of the Heart? Notwithstanding it is commonly conceiued that the most immediate cause is the auoiding of Vacuity that Arch-enemy of Nature. For the Faculty of pulsation although it be potentially in the Heart of the Infant in the Mothers wombe, yet it is not drawn into act till the Chest distending it selfe doth draw in the aire whereof that Vitall spirit is made, about whose generation that Pulsatiue vertue is wholly occupied. As for the motion of the arteries, we conceiue that they follow the motion of the heart, like as a Lute lying by another that is played vpon, will represent or returne the distinct Tune thereof.

I might heere enter into a large discourse of the excellency of the Heart; how in this Little world, it is like the Sun in the Great world; how it continually supplieth the expence of Vitall spirits; how it quickneth and strengthneth the Naturall heate of the whole body; how it is an Embleme of an excellent Magistrate; how the Lungs as fresh Fannes do temper the flaming heate of the hearts furnace, & how as bellows they kindle the same againe. For albeit this Sun of the body can neuer be truly eclipsed, this Geniall fire neuer extinguished without the dissolution of the *indivindum*; yet we see in many cold diseases of the braine and malignant exhalations from the womb, that to our sense this sparke of Sacred fire is deaded and put out, which notwithstanding by the helpe of the Lungs is afterward blowne vp into a luculent flame.

Beside the Organs of life, there belongeth also to this Region another no lesse admirable instrument of Nature, whereby the voice is so diuersified, that vpon the ground thereof that noble Science of Musicke hath beene from the beginning and still is infinitely propagated and yet the end or perfection thereof not attained vnto. But why do I go about in this place to exemplifie the administrations of Nature in this middle Region? considering that to say a little is derogatory from the worth of the argument; to say much were heere in vaine, seeing the following Discourse is purposely addressed for the Readers satisfaction therein.

CHAP.

CHAP. I.

Of the Thorax or Chest, and the Division of it.

THe middle belly is called *θώραξ*, of a word which signifieth to leap or dance, because in it the heart continually mooueth from the ingate to the outgate of life. It is comprehended by the ribs, or rather circumscribed by Ribs and Patell bones, and is separated from the lower Belly by the Midriffe or *Diaphragma*, and it is the seate or conceptacle of the vitall Faculty which harboureth especially in the heart, for whose sake this Chest or *Thorax* was made; the habitation of the breathing parts, and the shop wherein the voice is framed; and for this cause it is called of *Hippocrates* *χώρας testudo*, a Citterne or Crowd, because the sound of it maketh Musicke. It is placed betweene the vpper and lower bellies, that the Natiue heate which resideth in the Heart may be equally communicated to all the parts.

The Chest.
How it is limited.

The Chest
was made for
the heart.
Compared to
a Crowd.

The Figure of it is very capacious, being long and round like an Egge, whose magnitude may be guessed by the compasse it carrieth without. Before and behinde it is wider in man (saith *Aristotle* 2. *Hist. Anim.* 1.) then in other creatures; before, that there might be sufficient space for the Heart and Lungs to mooue and spred themselves in, both for the voyce and for respiration saith *Galen* in the 6. Chap. of his 13. Booke *de usu partium*, that we might haue abundance of spirits, for that in it the sprightfull blood is laboured of blood and aer, and the voice also is to be formed of the aer. Behind it is wide, that a man may ly at ease vpon his backe; in other creatures it is fashioned like the Keele of a Shippe; betwixt their fore feete in foure-footed Beasts for their better footmanthip; in Birdes for the nimbler

The Figure of
it.

Table 1. sheweth the body when all the bowels are taken out of the Lower Belly, and reclined backward, that the Scituation of the Midriffe might better be discerned, it sheweth also the other part of the Chest as yet covered.

TABVLA I.

- a The Midriffe in his seate.
- c the hole of the great artery cut open.
- b, i. Two fleshy originals of the Midriffe.
- k. The diuision of the Midriffe where it transmitteth the Artery.
- l. The leste perforation of the Midriffe giuing way to the gullet.
- m. The hole of the Midriffe through which the hollow veine ascendeth.
- n. The veine called *Phrenica*.
- o. The artery called *Phrenica*.
- pp. The sixt paire of Muscles of the thigh, called *Isas*.
- qq. The seauenth paire of Muscles of the thigh, which fil the cauity of the hanchbones.
- r. The fift Muscle of the backe.
- s. The Holy bone, together with some nerues arising out of the marrow thereof.
- t. The brest bone.
- u. The brest blade.
- xx The ribs.
- yy The intercostall Muscles.
- AB. The pectorall Muscle, or the first Muscle of the arme in his proper seate at *a*, the same separated as farre as his implantation at *B*.
- CC The Muscle called *Serratus maior* or the second Muscle of the Chest.
- D. *Serratus minor*, or the first Muscle of the Shoulder blade.
- E. The Muscle called *Deltoides* or *Epo-*
mus, the second Muscle of the arme,

his originall is at *t*. E. The *Clavicula* or Celler bone.

Hh

motion

motion of their wings when they flye. If it had beene otherwise framed in men (saith *Galen* in the 11. chapter of his 13. Book *de usu partium*) it would haue hindred the actions of their armes, and in Beasts it would not haue suffered their fore-bowes to haue beene so close brought to their chest, which would haue hindred them much in their gate.

The substance
and structure.

The substance of it is neyther altogether bony as the scull is, for then it could not haue beene mooued, nor altogether fleshy as the Lower belly, for then the Muscles would haue falne vpon the heart and the Lungs euen of their owne accord: wherefore that both there might be a space within the motion, and also all the whole frame of the instrument might be mooued together, the Muscles and the bones are set as it were by courses one beside another. For because the heart, one of the principall bowels, was to be seated in this Chest, it needed a more safe and secure muniment or defence, and therefore it is walled about with bones: but because the exceeding great heate of the heart stood in neede of much colde of aer, by which as by a fan it might be ventilated and preserued, it was necessary that the chest should be moueable, that in the dilatation of it aer being drawne into the Lungs might refresh the heart, and in the contraction the sooty vapors might bee expelled. Wherefore it was necessary that it should be composed of many bones, which because they should mutually follow the motion one of another, it was requisite also that they should bee ioyned together with some pliable substance, such as is a Cartilage or gristle.

The reasons of
it.

How rightly
called the
middle belly.

The Chest therefore is moued with Muscles and made vp and compacted with bones, and therefore is rightly called the Middle venter, not onely because of his scituation, but also by reason of his substance, neither wholly bony as the head, nor wholly fleshy as the lower Venter.

The Division
of the Chest.

The whole *Thorax* or Chest is diuided into a fore-part, which is called *σῆθος* or *sepeus pectus*, commonly the brest; the side parts called *πλαγὰς*, *Latera* the Sides, and the back part called *ὄπισθεν* or *μετὰ στήθεσιν* *Dorsum* the Backe, all which appeare in this precedent Table.

The parts of it

The parts of this Chest are some conteyning, some conteyned. The conteyning parts are common or proper, the Common are the Skin-scarfe or Cuticle, the Skin, the Fat: the Fleishy pannicle, and the Membrane of the Muscles. The Proper are soft or hard, the soft are fleshy, as the Muscles and the breasts, (of which we haue spoken before as rather belonging to the lower Venter, though for ornament and commodious vse they haue their seat here) or Membranous, as the *Pleura* and the *Mediastinum*.

The hard parts are bones or gristles, And first of the Conteyning parts, after of those conteyned, according to the order of Dissection.

CHAP. II.

Of the Skin, the Fat, and the skinned vessels of the Chest and the Necke.

How the com-
mon inuesting
parts differ
from the same
in other parts.
The Haires of
the arme-pits.

BEcause we haue entreated at large in the former Book of the common conteyning parts, we will onely heere shew how farre in this place they differ from the same in other parts, and so passe on vnto the Proper Conteyning parts.

Their vse.

The Scarfe-skin and skin of the Chest, do heerein differ from the same in the lower belly, because in the arme-pits it is hairy, which haires are called by *Hadrianus Iunius*, *Grande bala*, I thinke coyned of a Greeke word which signifieth to send forth, and a Latine which signifieth great (because in some men of all the haires of the body they come out the greatest and most bristlie) imitating *Plautus*, who to serue his turne maketh the word *Grande gro*, to stalker on with wide steps, of *Grande* and *eo*. But the vse of these haires is, that those parts which sweate soonest and most (for heere are the Emunctories of the heart, vnto which it sendeth his excrements as we see ordinarily in plague fores) might not bee galled or fretted with the often and strong motions of the armes. In many men also the fore-part of their Chest is more hairy then the *Abdomen*, and as in the Lower belly is the Nauell, so in this middle belly are the nipples of the breasts perforated as we haue saide in both sexes.

The fat in this place is not so plentifull as in the belly (excepting the breasts) least with his waight it should hinder respiration.

Betwixt the fleshy membrane and the skinned runne certaine vessels called *Skin-veines*, some by the sides of the necke and the head from the two outward iugular veines, which with their furcles runne along the fore-part of the necke; others on the backe-side from a

branche

branche which the shoulder veine called *humeraria* sendeth vpwrd, others are disperfed through the foreparts of the Chest, to wit, two coming from the *Axillary* veines, one of which is a branche of the *Axillary* veine, the other of the *humeraria*, like as through the back are difseminated certaine small branches from the same veines. The Arteries which come hither are exceeding small and capillary: Finally, there are certaine nerues sent from the nerues that ly lower vnder the muskles and the skinne, but two more notable then the rest which meete about the teates, which are the cause of their so exquisite sence.

Arteries.
Nerues.

CHAP. III.

Of the muscles of the middle belly and of the parts of the necke.

THe Muscles of the middle venter are double, for either they lye vpon the ribbes or are scituated betweene them, yet all of them are not made onely for the motion of the Chest; for albeit they arise from the Chest, yet they moue either the armes or the shoullder blades or the backe or else the Chest it selfe, and such are called the *proper muscles of the Chest*, and these muscles are placed without or within: those that are seated without are on the fore-part or on the backe-part.

On the fore-part there are three on either side.

1. *Pectoralis*, the pectorall, and it is the first muscle of the arme, which is broad and large and seated vnder the Pappes.
2. *Serratus maior*, the greater saw, the second muscle of the Chest which lyeth vpon the ribbs, and to them is inserted as it were with fingers, whence it hath the name of the saw, and occupieth especially the side.
3. *Serratus minor*, the lesser saw, or the first muscle of the shoullder-blade, it is triangular, and lieth vnder the pectorall muscle.

Muscles on the
fore-side of the
chest.

On the back part there are ten on either side.

1. *Cucullaris* or the *Munks-hood* the greater part of the second muscle of the *scapula* or shoullder blade.
2. A part of the third muscle of the arme called *Latissimus* or the broadest muscle, because it taketh vp almost all the back-part of the lower belly.
3. *Rhomboydes*, the third muscle of the shoullder-blade scituated vnder the *Munks-hood*.
4. *Serratus Posticus superior*, the upper hinder saw, or the fourth Muscle of the Chest lying vnder the *Rhomboides*.
5. *Serratus posticus interior*, the lower hinder saw, or the fift muscle of the Chest, scituated vnder the muscle called *Latissimus*.
6. *Sacrolumbus*, or the sixt of the chest.
7. *Longissimus*, the long muscle, the 2. of the backe.
8. *Semi-spinatus*, the fourth muscle of the backe.
9. *Splenij pars inferior*, the lower part of the *splenium* or of the first muscle of the head placed vnder the upper hinder saw.
10. *Complexi pars inferior*, the lower part of the *Complexus*, or the 2. muscle of the head.

Muscles on
the back-side
of the chest.

On the inside there is one triangular, the sixt of the Chest; lying vnder the lower part of the brest-bone, of which in the 19. Chapter of this Book. Those muscles that are betweene the ribs called *intercostales* we shall intreat of by and by, when wee haue numbred vnto you the parts of the necke.

On the inside.

I do in this place describe the necke, because the chiefe parts therein contayned belong vnto the vitall parts, as the muscles of the voyce, the weazon, the *larynx* and such like.

It is therefore called *Collum à colendo*, because we vse to adorne this part with chaines and iewelles. *Galen* called it *ραχυνος* because of the sharpnesse of the bones of it. It is a middle part betweene the Chest and the head made for the vse of the Chest and the Lungs; long that in the length of it the voice might be better modulated or tuned, and therefore birds haue the most variety of tunes of any vnreasonable creatures, but fishes because they haue no Lungs and so are mute, haue no necks, but al creatures that haue Lungs haue also necks. It is round because of the bodies which are seated in it. The parts contayned in it are the iugular veins external and internal: the Arteries called *Carotides*, nerues of the sixt paire and

The necke.

The figure.
The parts con-
tained.
Concerning
the muscles of
it.

the recurrent nerues : all which are placed on the sides, but before, the weazon called *aspera arteria* or the sharpe artery and the gullet called *oesophagus* of which we haue spoken before. The muscles which are in the necke are many; some moue the necke it selfe, some the *larynx* or throtle, some the bone *Hyois*, some the tongue, some the head, the lower Iaw and the shoulder blades. Of these some are scituated before some behinde. Behind those that follow which we will name as they lye each vpon other.

1. *Cucullaris pars superior*, the vpper patt of the *Munks-hood* or the second muscle of the shoul-der blade, descending from the *occipitium* or nowle of the head.
2. *Leuator*. The fourth of the shoulder blade seated more toward the sides.
3. *Splenius*, The first muscle of the head.
4. *Complexus*, The second of the head.
5. *Recti maiores*, The third paire of the head.
6. *Obliqui superiores*, The fift paire of the head.
7. *Obliqui inferiores*, The sixt paire of the head.
8. *Recti minores*, The fourth paire of the head which lie vnder the second muscle of the back.
9. *Transuersalis*, The third of the necke.
10. *Scalenus*, The second of the necke, it lieth on the side from the first rib into the necke.

Before; these, beside those which grow to the iaw and are vnder the chin.

1. *Quadratus seu Platysma myodes*, The first muscle common to the cheeks and the lips.
2. *Mastoydes*, The seuenth of the head, from the pattell bone to the sides of the head.
3. *Sternohyoidei*, The first paire of the bone *Hyois*, which lye vpon the wezon.
4. *Coracohyoidei*, The fourth paire of the bone *Hyois* seated at the sides.
5. *Oesophagii*, The third paire of the common muscles of the *Larynx* or throtle.
6. *Longi duo*, The first muscles of the necke.

But we returne vnto the Chest, and first to the *Intercostal* muscles as being proper only to the Chest, and therefore we will here follow their description more accuratly in this place.

CHAP. IV.

Of the Muscles betweene the Ribbes called *Intercostales*.

The *Intercostal* muscles.

Their number.

THe muscles which are wouen between the ribs and do fill vp the distances between them are called *μεσολαυροι Intercostales*. Gal. in his Book *de usu respirationis*, accounts them according to the 11. ribs 22. otherwhere thrice so many and two ouer, that is 68. as saith *Archangelus*, but he himselfe reckons them 34. we wil account them 44. For because there are on either side 11. distances, and in euery distance there are 2. muscles, there are on either side 22. Of which some are external [tab. 1. 77] which are 11. & so many internal or within. These are fleshy and narrow but long, according to the portion of the distances; their fibres are carried obliquely from one ribbe to another in a contrary position, so that those of the inward and outward muscles lying one vpon another doe mutually intersect themselves in the manner of a Saint Andrewes crosse, or this letter X. The outward of these muscles or the superior are carried from the lower parts of the vpper end of the ribbes to the vpper parts of the lower end of the ribbes: for they beginne in the backe part from the transuerse proccesses of the rack-bones to which the ribbes are annexed, and passe with their fibres obliquely forward all along the bought of the ribs to the beginning of the cartilages; (where the bony parts of the ribbes doe end) and are ioyned to the breast-bone; they want tendons because of the narrownes of the place, neither do they reach thorough the distances of the gristles.

The interior or inward muscles quite contrary are carried from the vpper part of the lower ends of the ribbes to the lower part of the vpper end of the ribs, but do not beginne from the proccesses of the rack-bones, but from that part in which the ribs are bent, and run forward with their oblique ascendent fibres, and fall vpon the distances of the ribs as well where they are bony as where they are gristly, and keeping alwaies the same series or course of fibres passe onto the very bones of the brest, yet so, that in the distaces of the gristles they are lifted vp a little to the outward face of the Distance, and so supply the places of the exterior where they are defectiue or wanting. And this is the cause why the Fibres in the di-

Diuers fibres
one vnder an
other.

stances

ſtances of the griſtles do appeare diuerſe from thoſe in the diſtances of the ribs themſelues. And if you take off theſe Fibres betweene the griſtles, you ſhall finde alſo others vnder them of another poſition, which are the Fibres of the ſixt Muſcle of the cheſt which is called the triangular Muſcle.

From the vndue diſtinction of theſe Fibres, ſome haue made 68. intercoſtall Muſcles, when indeede they are but 44. reckoning thoſe differing Muſcles which are betwixt the bony parts of the ribs [Tab. 2. fig. 1, C C] from thoſe that are betweene their griſtly parts. [Tab. 2. fig. 1, D D] And whereas the diſtances of the ribs are eleuen, ſix of the true ribs and five of the baſtard ribs; they think, that there are foure in euery diſtance of the two ribs, two where they are bony, and two where they are griſtly, and thoſe internall and externall, but in euery diſtance of the baſtard ribbes they will haue but two, one externall and another internall.

Auiſen.

How Auiſen and Columbus were deceiued.

But we muſt further obſerue, that the outwarde Muſcles, by how much they ariſe neerer to the rack-bones, by ſomuch the ſooner do they determine in the fore-parts of the ribs; ſo againe the inward, by how much the later they ariſe from the bent of the rib, by ſo much do they come ſhort of the breſt-bone.

A note concerning the originall & end of theſe Muſcles.

Why they are obliquely placed and interſect themſelues *Varolius* hath elegantly ſhewed; prouing that it was ſo neceſſary for the dilatation and conſtriction of the cheſt. For becauſe the diſtance which is betweene one rib and another, was not answerable to the length of the Muſcles required neceſſarily for the dilatation and conſtriction of the Cheſt, therefore they are diſpoſed betweene the ribs not with right Fibres (and euen *Galen* intimated ſo much in the 23. Chapter of his Booke *De Diſſectione Muſculorum*, but was not vnderſtood, at leaſt not obſerued by the Ancients) but with oblique; and that this helpeth dilatation we may euidently ſee, becauſe euery thing retcheth more being drawn obliquely, then if it be drawn right out, as Cloth, Leather and ſuch like, which we call drawing Biace. For conſtriction alſo it is as fit, becauſe the Muſcle is contracted more or leſſe according as it is greater or leſſer. Wherefore, if they had had right Fibres, they muſt needs haue beene ſhort and ſo their contraction much ſtraightned, neither could they haue ſufficiently bound in the Cheſt.

Why theſe Muſcles are obliquely placed of neceſſity.

How they help dilatation.

How they help conſtriction.

Moreouer, becauſe euery Muſcle drawes according to the courſe of his Fibres, therefore leaſt the ribs in their oblique motion ſhould ioyn cloſe together, the intercoſtall Muſcles are framed double (a thing vnknewne to the Ancients) that with their contrary fibres they might interſect themſelues. For when two oppoſite bodies do together drawe obliquely, there reſulteth by their oppoſition one ſtraight and direct motion.

Why theſe Muſcles are double.

The Uſe of theſe Muſcles (as moſt Anatomists haue recorded) is to conſtringe and dilate the Cheſt. Of the exterior in expiration to beare down the ribs together, and ſo to ſtreighten the Cheſt; of the interiour to diſtend and ſeparate the ribs, and ſo to enlarge the cavity of the Cheſt for inſpiration. But when *Galen* ſaith in the 15. Chapter of the fiſt Booke *de uſu partium*. That the intercoſtall Muſcles helpe the Midriffe, that they might draw the Cheſt inward, it is to be vnderſtood not that they further the proper motion of the Midriffe, but that they moue the ribs inward; which is their proper function. But what kinde of motion is this? For either they bring one ribbe to another or ſeuere one rib from another, or they liſt vp the ribs or preſſe them downe. The two former motions they performe not; for there is no uſe of any ſuch motions, neither can any of them of it ſelfe as a voluntary inſtrument dilate the place wherein it is, or ſeparate one rib from another; neither can they liſte vp the ribs, for the Muſcles which liſte them vp are placed without the cheſt and haue their originall from elſewhere, and are called the proper Muſcles of the Cheſt.

The uſe of Muſcles.

Galen. How the intercoſtall Muſcles helpe the Midriffe.

It remaineth therefore that they do preſſe the ribs only, and that but lightly, that the contraction of the cheſt may ſo become equall, being drawn downe together with their contraction and the contraction of the Midriffe: and ſo that is made good which *Galen* ſaith, that they helpe the Midriffe. We may alſo ſay they help the ſixt Muſcle of the cheſt which is vnder the breſt-bone. Yet we will not deny but that they confer alſo to dilatation, but that by accident as *Fallopins* and *Platerus* haue obſerued, to wit, as they ſupply the place of a Ligament, and ioyn the ribs one to another. For when the lower ribs are drawne downeward and dilated by the proper Muſcles of the cheſt; or when the vpper ribs are eleuated by their proper muſcles, it is of neceſſity that the middle ribbes ſhould follow the draught, and ſo the middle diſtances in deep Inſpirations are dilated by the helpe of the intercoſtall whether as they be muſcles or as they bee ligaments; which yet they could not performe if the

They only depreſſe the ribs.

How they conferre to dilatation.

They are rather moued then moue.

Another way how they dilate the distances of the ribs.

proper muscles of the Chest were wanting: and therefore we may more properly say that in this case the intercostall muscles are moued by the proper muscles of the chest, then wee can say they moue of themselves, though their motion is not meereley constraigned but begunne and as it were led the way by other muscles; and haply such a kinde of motion there is also betwixt the *Serratus maior* and the oblique externall muscles of the *Abdomen*. There is another way also how the middle distances of the ribbes may bee dilated by the intercostall muscles; for if on either side the first muscle of the chest (which is called *subclavius*, situated betwixt the first rib and the patell bone or clauicle and hath oblique fibres like the intercostals) do draw vp the first ribbe, then by consequence the other distances vnder shall also in some sort be dilated.

CHAP. V.

Of the Midriffe called Diaphragma.

The Midriffe. The names & reasons of them.

Madnesse in Maids.

It is a Muscfe.

He Midriffe called in Greeke by *Plato διαφράγμα*, of a word which signifieth to distinguish, because it distinguisheth or separateth the instruments of nourishment from the instruments of life and respiration; and in Latine *septum transversum* or the ouerthwart partition, because running ouerthwart the bulke of the body it parteth it into 2. venters [as is manifest in the 1. tab.] This the Ancients as *Hippocrates* in his Booke *de principijs* called *σπέρμα*. i. the minde, not that it hath any intelligible faculty, but because of his notable sympathy with the Brayne: for when this is affected, instantly the minde and all the senses are out of order, and vpon the inflammation of it, followeth a kinde of *phrenitis* or rather a continuall aberration of the mind, and in maydens sometimes madnesse it selfe, as *Hippocrates* sayeth in his Booke *de iis quæ ad virgines spectant*.

It is the 65. muscle seruing for respiration, and differs from all the muscles of the body in excellency, scituation, figure and action. It is one, very great and strong, common to both sides, and as large as the capacity of the lower part of the Chest; as Table 1. declareth.

His scituation in the cavity of the body is ouerthwart and oblique [looketab. 1. a] and declining somewhat downward ouer all that vtmost compasse of the Chest which is limited by the gristles of the bastard ribbes and the lower part of the breast-bone: This muscle whilest it is at quiet remayneth lifted vp as we see in dead carcases, & maketh a great cavity, but when it worketh and is contracted it beareth downeward.

The frame of the Midriffe.

The connexion of it.

Why it is nervous in the midst.

More of the Connexion.

The figure.

The midriffe riseth with two long and fleshy productions [Table 1. and table 2. fig. 2. b i] from the bare rack-bones of the loynes to which it adhereth very strongly, and a great way together, for euery muscle must haue something to rest his head vpon, and most commonly it both ariseth from and is implanted into an immoueable part. The two productions at the sides of the great Artery doe cleaue to the muscles of the loynes [Tab. 1. pp] and becoming broader by degrees doe meete at the eleuenth rack-bone of the Chest, and so make the muscle circular or round, and it is tyed in his fleshy circumference to the inside of the Chest and the ends of the bastard ribbes all along the twelfth ribbe at the lower part of the breast-bone and at the breast-blade [table 1. u] which was made for his defence; but in the middest it endeth into a strong membranous and nervous tendon [tab. 2. fig. 2. b c d] framed of very firme sinewes and membranes. Now it was very necessary that it should be nervous in the middest, partly, for the more security, that it might endure diuers motions without hurt, and not be endangered with payne because of their violence: partly that the hollow veine [tab. 1. and tab. 2. fig. 2. m] and the *æsofagus* or gullet [tab. 1. and tab. 2. fig. 2. l] which passe through it, might not be streightned, and so the course of meate and bloud hindered. Wherefore howsoeuer this muscle worketh, seeing onely his fleshy fibres [tab. 2. fig. 2. f g] are contracted or drawn together, the nervous part about those vessels is neuer constringed: but rather when the fibres are contracted the nervous part from the center to the circumference is distended, and the holes through which those vessels go, wider opened. Moreover, it is vnited to two of the muscles of the *Abdomen*, the oblique ascendent and the transuerse, and aboue, it is so straightly ioyned to the purse of the heart or *pericardium*, that without tearing it cannot be separated from it.

The figure of it is almost [table 2. fig. 2 sheweth it] circular, round like a Plaice or Thorn-backe, or likest a racket which we vse in the Tennis-court, especially if the racket be straight stretched, and the processes are very like to the handle of the racket.

His

His substance is partly [Tab. 2. Fig. 2. fg] fleshy partly neruous [Tab. 2. Fig. 2. a b c d] as if it were compounded of two broad circles, but ending in one part in an acute angle; [table 2. Fig. 2. d] of which the fleshy circle is on every side annexed to the chest [see the first Tab.] and compasseth the other neruous circle which is in the center, to which as vnto a center many fibres like lines do runne from the circumference and as it were from the beginning or originall of the muscle, which that you may rightly discern, you must separate the *Peritonaum* or rimme from the midriffe, which in Hogs may be done easily, but in a man and a dog not without difficulty.

It hath a double membrane one lower from the *Peritonaum*, another vpper arising from the *pleura* with which it is compassed for more strength; although it haue another coat of his owne but a very thinne one, that it might bee distinguished from all other parts by proper circumscription. Veines it hath arising from the trunk of the hollow [tab. 1. m, a b. 6. A] veine called *Phrenice* (sometimes also it receiveth branches from the fatty veine called *Adiposa*) which are accompanied with arteries from the great artery [Tab. 1. e] called also *Phrenica*; [the veines Table 1. n, tab. 6, c the arteries tab. 1. o, table 13. K K] the veines carry vnto it bloud for his nourishment; the arteries vitall spirits together with the vitall faculty, and beside by ventilation with their motion they preserve his naturall heat.

It hath two nerues [Table 2. Fig. 1. P P] proceeding out of the lower rack-bones or *vertebra* of the necke made of three furcles on each side (and this is peculiar to this muscle, for other parts vnder the patell bones or *clauicles* receive none from the marrow of the necke) which nerues being carried through the cavity of the Chest are contorted or wound about the *Mediastinum*, and by it fastned and stayed aloft least they should be hurt. And it was necessary that these nerues should come from an vpper place, that they might more equally extend their action into every part of it: wherefore they are disseminated through his whole substance, that they might affoorde vnto it all sence and motion, whence it is of very exquisite sence, and when it is iniured for the most part death followeth.

It hath two passages or holes, one on the right hand [Table 1 and Table 2. fig. 2. m] in the middle neruous part for the ascent of the hollow veine out of the vpper and gibbous part of the Liuer vnto the Heart; another on the left hand [tab. 1. and tab. 2. fig. 2. l] a little backward and greater, through which passeth the *Oesophagus* or gullet and two nerues vnto the stomacke, vnto which notwithstanding his membranes do grow and encompasse streightly and very strongly.

At the originall or beginning of this muscle or midriffe betweene his productions [tab. 1. and tab. 2. fig. h i] at the racke bones, there is a diuision [tab. 1. and table 2. fig. 2. k] resembling a semicircle or halfe Moone for the descent of the great Artery and the veine without a peere or *non parill*; and for nerues of the sixt payre fixed to the ribbes which are carried vnder the *pleura*; and this diuision imbraceth the racke-bones vpon which the great artery leaneth.

The chiefe vse of the Midriffe, which *Galen* found out, as appeareth in the 15. and 7. Chapter of his 5. Booke *de vsu partium*, and which dependeth especially vpon his scituation, is that it might be the organ or instrument of free, gentle, and voluntary respiration or breathing, euen as the instruments of violent or deepe breathings are the 64. muscles which are about the Chest exactly dilating or contracting it. For his fibres being equally retracted or drawne together, all the bastard ribs are drawne toward the centre of the chest, and so they draw the vtmost parts of the Chest vnto the rack-bones, and constringe or contract the lower part, whereupon the Midriffe is lift vp, streatched and serueth for expiration. Hence it is that in a dead body it alwayes appeareth contracted and streatched, for the life endeth with expiration, and if the Chest be perforated within the ribs or Midriffe it falleth straight loose downward, and suffereth the Liuer and the stomack which before were somewhat suspended, to fall. But when the fibres are loosened the Midriffe falleth; for the bastard ribs are loosened, and the lower parts of the Chest, and consequently the Lungs are dilated and so we draw in breath: wherefore when the Midriffe is hindred or affected, then must needs follow difficulty of respiration, as *Galen* saith in the 8. Chapter of his 4. Booke *de locis affectis*. This motion according to some authors, (*Archangelus* among the rest) is mixed of a voluntary and a naturall motion, voluntary it is but not simply, because there is a necessity which vrgeth and exacteth this motion: as in respiration a necessity of cooling the heart vrgeth, euen as in vnburdening the belly & making water the excrements do vrge & prouoke the *sphincter* muscles of the Fundament and of the Bladder.

 Q, A veine which together with the nerue descendeth to the midriffe.
 RSTV, A part of the lungs in the left side of the cavity R, and T, shew the vpper lobe, S, and V the lower.

Figure II sheweth the midriffe taken out of the body.

- a, The midriffe.
 bc de, The sinewy part thereof.
 fg, The fleshy part thereof.
 hi, Two fleshy originals.
 k, A diuision or perforation of the midriffe where through the great artery is transmitted.
 l, The perforation on the left side, which giueth way to the gullet.
 m, The right perforation through which the hollow veine ascendeth.

Another vse.

Another vse of the midriffe is to ventilate or fanne the *Hypochondria*, especially the Liuer, because in his conuex or vpper part it wanteth Arteries to doe that office; as also the moyst vapours containd in the capacity of the lower belly, least being at rest they should putrifie and corrupt; for which cause *Hippocrates* in his first Booke *de morbis mulierum* calleth it the breather or bellows of the lower belly.

A third vse.

Another vse of it is, as *Galen* aduiseeth vs in the 9. Chapter of his second Booke *de motu musculorum*, to helpe forward the expulsion of the excrements and the Infant in trauell by helping the muscles of the *Abdomen* as wee haue shewed in the former Booke; for which it is the more conuenient because of his oblique scituation. For aboue it presseth the gurttes as it were with hands, and so driueth the excrements downward, which otherwise might as well be excluded vpperward as downward if this helpe were not.

The last vse of the midriffe.
Plato.
Aristotle.
Plinius conceit

The last vse is, that according to *Plato*, it might deuide the *Irascible* or Angry part and faculty of the Soule from the Concupiscible and lustfull; or according to *Aristotle*, it might distinguish the naturall parts from the vitall, the ignoble from the noble, that the vapours which arise from the lower parts as from the sinke of the body, might not offend the heart the seate of life and sence as he thought. *Plinie* ascribed to it the subtilty or nicenesse of the wit, and esteemed it the seate of mirth which appeareth by tickling: for if the skinne about the *Hypochondria* be gently touched we are tickled and laugh presently; but more rare was that of a young man in my knowledge, who had the cause of an Epilepsie in his foot, which at certaine times would rise vp and might be stayed by binding the legge and thigh, but when the vapor or breath came vp about the place of the Midriffe, then would he laugh extreamly and presently after fall in his Epilepticall fit. But the Philosophers reason

son was, because the motion commeth presently to that place; for that the skin is thin and warmeth the part, though lightly yet enough to open it, and so moueth the minde euen against the will of him that is mooued. For in the single Combats of Sword-Fencers (called *Gladiatores*) at sharpe vsuall in those times, some haue bin seene to dye laughing when they haue bin thrust through about that part.

And the reason why onely men of all creatures are ticklish, is partly the thinnesse of the skin, partly because a man onely of all creatures can laugh; for titillation is the cause of Laughter, when such a part is mooued as from which the affection may rise vp and fill the wings of the nose.

How tickling
causeth laugh-
ter.

CHAP. VI.

Of the Membrane called Pleura.

He *Pleura* is a Membrane taking his name from the Ribs which they call *πλευράς*, because it is stretched vnder them al, excepting the twelfe, and truely it is called a Membrane because of his substance, and a coate because of his Vse.

The Pleura.

It is a Membrane enclosing the whole cavity of the Chest, wherefore his Figure and magnitude is answerable to that cavity, which is Semiouall or like halfe an egge. It ariseth and is bred of spermatieall filaments or threds of the seed and the mothers blood powred betweene them after the manner of a *Parenchyma* or as the flesh of the Liuer or other of the bowels; or it is produced from the Membranes of the Braine which inuest the Marrow of the backe, which being brought together with some Nerues into the Chest do on both sides frame it; wherefore there it is thicker and cleaueth strongly to the rack bones or *Vertebra* of the backe, from which vnlesse it be broken it cannot be separated, because from thence it hath his beginning of the place or production.

His figure and
magnitude.

His originall

It is tyed backward to the racke bones of the backe, which is the reason that some haue said it ariseth from their Ligaments, or from the Ligaments of the *Vertebra* of the Chest as *Fallopini*; before, it is tyed to the brest-bone; on the sides to the Membranes of the intercostall Muscles, and to the Membranes which immediately compasse the rib bones; aboue to the Clauicles or Patel-bones; below in his *Basis* as *Galen* calleth it, 5. *Administ. Anat.* 8. or bottome, to the Midriffe, and in the middest vnto the Lungs and heart-purse or *Pericardium*.

His connexion

His substance is like that of the *Peritonaeum* or rim of the belly, but in strength and thic- nesse somewhat exceeding it; for because it was to passe betweene the bonie hardnesse of the ribs and the soft bodies of the Lungs, it was ordained neither too soft nor too hard, yet somewhat hard the better to defend the Vital parts; thight and close wrought yet light, that the weight of it might not hinder the motion of the Chest, but strong and neruous, hard to be diuided, and sometimes in some diseases of the Chest it hath beene obserued by *Platerus* to grow ten fold thicker then vsuallly it is.

His substance
and structure.

It is all ouer double, partly because of the hardnesse of the bones, that the inner side which is very sensible might not be hurt by the continuall motion of the Lungs, partly that betwixt both the Membranes the intercostall vessels might more safely passe.

It is double &
why.

The one of these is thicker, especially about the backe where it may be cleane seuered from the ribs; and it is harder because of the continuall motion of the Lungs and his inner face is smooth and smeared ouer with moysture, the vtter superficies or face of it is vnequal and rugged. The other is thinner, and of some is called the Membrane compassing the ribs. Betweene these two is the matter of the Pleurisy oftentimes collected (because there are vessels which run betweene them) and not onely betweene the Pleura and the intercostall Muscles. From this Membrane sometimes on one side sometime on another, (as *Vesalius* and *Valnerda* haue well obserued) but especially on the left side, doe certaine sinnowy Fibres come; by whose interposition the Lungs are strongly tyed to this *Pleura* in men when they be in health, and among them is seene some small portions of fat neere the rack-bones of the back where the vessels are greater, as it is in the *Peritonaeum*; but this is but rare. And as the intercostall Muscles like other Muscles haue their proper Membrane, so the ribbes like other bones are compassed with their *Periostion* or proper and immediate Membrane, which *Vesalius* that oculte Anatomist tooke to be one of these Membranes which we haue described.

Where the
matter of the
pleurisy lyeth.

It

His perforati-
ons.
Aboue.
Below.

At the sides.
His vessels.

His vse.

It is perforated where it sendeth vessels into the Chest or out of it. It sendeth out aboue the iugular and Axillary Veins, and the *Carotides* or Axillarie Arteries; but it letteth in the Gullet, the Weazon, and a Nerue of the fixt paire belonging to the Midriffe; below, it is perforated at the *Diaphragma* or Midriffe; for the ascent of the Hollow veine, & the descent of the Gullet as was saide in the former chapter; at the sides for the intercostall vessels. The vessels which are tied vnto it as they passe vnto the Neighbour parts doe lend it small branches which come most plentifully from the Mammary and intercostall vessels. Hence it is that it is often inflamed with great tension and a pricking or goading paine.

His vse. His vse is much like the vse of the *Peritonaeum* or Rimme in the Lower belly; for as the *Peritonaeum* is stretched about all the parts of the Lower belly, and affordeth vnto euerie one of them a common coate; so the *Pleura* is stretched vnder all the cauitie of the Chest, and giueth a common coate saith *Galen* to al the instruments of breathing, as also to the midriffe and the intercostall muscles and the vessels, and defendeth and knitteth them altogether. It giueth also to the vessels a safe wastage and a kinde of stability, and where it is stretched vnder the ribs, it serueth the Lungs for a defence, that they light not vpon the bare bones when they dilate themselves in the gathering in of breath, & so be hurt with their hardnes, and beside that the lungs in their motion do not intangle themselves in the distances of the ribs.

CHAP. VII.

Of the Mediastinum.

The Mediasti-
num.
His Names.

He *Mediastinum* so called, because it mediateth or diuideth the Chest in the midst. *Columbus* calleth it *Intersepimentum* and *dissepimentum*, as a hedge that diuideth two Pastures. It is double: The right [tab. 3. G G the right, H H the left] and the lefte, which *Galen* calleth *Septum Diaphragmatis*, because they diuide the cauity of the Chest, which the *Pleura* encompasseth into two parts. For the cauity of the Chest is not one open and continuall, but is diuided by these membranes. Wherefore in the middle of the chest there is one on either side which passeth from aboue downward according to his Longitude euen vnto the Midriffe, and backward from the Breast-bone vnto the Racke-bones, so that the chest is by this meanes diuided into two circles, or if you had rather, they frame a certaine Triangle of vnequall and oblique sides, for they haue space enough to resemble this Figure, because of the deapth and length of the Breast.

His situation.

His originall.

His substance.

These Membranes do arise from the *pleura*, which where it climbeth from his originall on either side to the sides of the breast-bone, creepeth so backe againe towards the ridge where his beginning was, that it attaineth from the midst of the breast to the very spine of the backe. These are thinner then the *pleura*, and softer that they may more easilie follow the motion of the heart, on the outside as they looke to the Lungs to which they sometimes grow, they are smooth, and oftentimes about the vessels they appeare interlaced with much fat, so as they may bee compared to the Kal or *Omentum*; on the inside rough, because of the Fibres with which the Membranes are ioyned, as also to the *Pericardium*; and in the hollow of the throate the *Thymus* so called (of which we shall heare afterwards) groweth vnto them. Heere, according to the length of the racke-bones of the backe vnto which they are ioyned by the mediation of the *pleura*, they euen touch together, and make but a very narrow cauity, but are after by degrees seuered and at the Breast-bone stand as wide asunder as the Breast-bone is broad, to which they cleaue euen from one end of it to the other; and this distance [Tab. 3. L L] is intertexed or wouen betweene with diuers threddy Fibres and Membranes; but they are widest asunder & make the largest distance at the *Diaphragma* or Midriffe, to which they are ioyned as [Tab. 2. fig. 1. K] as his neruous part reacheth, in somuch that this cauity which is smooth and moist, before containeth the heart knit vp in his purse and the hollow-veine ascending vpward, and behinde the gullet with the stomack Nerues.

Their distace.

Where the distance is widest.

A disease resembling a Pleuresie.

In the fore-part of this Cavity there is oftentimes a matter conteyned, which causeth a disease resembling a Pleuresie, which matter if the breast-bone (saith *Columbus*) bee verie cunninglie perforated may bee safely drawne out. In Dogges this Cavity is more large but hath no such webbe of Fibres as in a man. The Veynes and Arteries that it hath are very

Table 3. sheweth the middle belly before and at the sides, bared from the skinne to the Muscles, wherein also the brest-bone with the gristles of the ribs are separated from the Mediastinum and reflected backwarde, that those things which are conteyned in the Chest may better bee perceived.

AAA. The middle *A.* is the inside of the brest-bone; the other two shew the inside of the gristles and the ribs ioyned together.

BC. The *Mammary* veines descending vnder the brest-bone vnto the right Muscles.

DE. The *Mammary* arteries descending.

F. Certaine glandules or kernels about the collar bone, appointed to secure the distribution of the vessels.

GG, HH. The right and the left side of the *Mediastinum*, which before the diuision of it did grow vnto the brest-bone.

IK. The right and left superficies of the same *Mediastinum*, which is next to the lungs.

LL. The distance betwixt the membranes of the *Mediastinum*.

MM. This swelling place sheweth the scite of the left part of the heart.

N. The vpper part of the right Lobe of the Lungs.

O. The lower part of the right Lobe of the Lungs.

P. The vpper part of the left Lobe of the Lungs.

Q. The lower part of the left Lobe of the Lungs.

RR. The Midriffe separated from the brest-bone, and from the tops of the

gristles which cleaue vnto it. *S.* The Gristle called the brest blade. *TV.* The skindrawne downward from the foreside of the Chest.

very smal from the *Mammary* [tab. 3. *BCDE*] which passe from the hole of the throat downward vnder the brest-bone, from which in their passage as also from the vein *Non-parit* they borrow a sacle. [tab. 2. fig. 1. *OO*, from the *Mammary* vessels.] Moreover in a man it receiue a good large veine out of the hollow of the throate, which descendeth accompanied with a Nerue [tab. 2. fig. 1. *Q*] by the whole length of both the Membranes to the Midriffe, but groweth onely to their outside, sometimes also it receiue small branches from those Vessels which we haue before named *Phrenice*, that is, the vessels of the Midriffe.

The vse of this *Mediastinum* or bound hedge is first to hold the heart vp suspended; for being tyed to the purse of the heart it must needs do that office, lest if it had no such ty, but hung down at liberty, in the diuerse positiō of the body it might fall to the sides, to the brest, to the spine, or else downward. Secondly, this serues to strengthen and secure the passage of the vessels. Moreover, it incompasseth the parts conteyned in the Chest, that they should not hurt the Lungs in his motion. And finally, it diuideth the Chest into two parts or caviities which is their chiefe profit saith *Galen* in the 3. chapter of his 6. Booke *de respiratione*. so that if one part be hurt, yet the other may be safe: as was haue knowen a theefe Anatomized who was a strong and stout fellow, but had one side, that is, the right side of his lungs withered almost all away and dried vp into a very small quantity, but the other remained faire and fresh as any other mans. So in wounds, if one part bee very sorely wounded, so that because of the entrance of the outward aer the motion of the Lungs do cease; yet the other part will not be wanting to susteine life by performing his part of the worke. For, if both parts of the Lungs be wounded any thing wide through, the voice and respiration too must

must needs perish : although I saw when I was a Boy a Knight wounded, quite thorough the backe on both sides the bone, and so deepe that on both sides in his dressing his breath would at the mouth of the wound blow out a Candle, and yet the Patient hath perfectly recovered. And this shall suffice to have spoken of the Conteyning parts of the Chest, especially of those that are soft, for the hard parts which are the bones and the gristles, will fall out better to be handled afterward. Now wee will pursue our Historie vnto the parts conteyned.

CHAP. VIII.

Of the Thymus and Purse of the Heart called Pericardium, and the water conteyned therein.

med.

Note.

The Pericar-
dium or purse
of the heart.

His Figure.

Connexion.

His originall.

His substance
and the rea-
sons of it.

He contained parts of the Chest are, Bowels & vessels. The Bowels are 2. the heart covered with his purse and the Lungs. The vessels are branches of the great veine & the great artery, borne vp in the hollow or lower part of the throat with a glandulous body called *Thymus*, double Nerues from the marrow of the racke bones of the Chest, from which the intercostal nerues do come also from the marrow or substance of the braine contained within the scull, from which the sixt paire or coniugation proceedeth, and from it the *Costalis* or the sinew of the ribs, the Stomachicall and Recurrent both the right and the left; and finally, the Weazon called *Aspera Arteria*, and a part of the *oesophagus* or Gullet. But first of the *Thymus*.

The *Thymus* which *Galen* in the fourth Chapter of his sixt Booke *De usu partium*, calleth *Thymus*, his Interpreter, the lowest of the Glandules; is a glandulous body soft and spongie. (*Galen Administ. Anat.* 7, 9. calls it the great and softest Glandule) which in the vpper part of the Chest neere the hole of the throate lyeth vnder the brest-bone, and serueth for a pillow or boulder to secure all the diuisions of the Hollow veine and the great Artery, and all the sproughts that come from them, which are in this place very many and diuerse, going to the armes and the shoulder-blades; as also the Hollow-veine it selfe, that it be not hurt by the hardnesse of the brest-bone, from whom in lieu it receiueh certaine small vessels. For this is an ordinary and perpetuall worke of Nature, that wherefoeuer she diuideth a great vessell, there she interponeth a Glandule to fill vp the diuision. This is that part in Calues, which is accounted among the delicates of the Table, and is called *Lactes* or the sweete bread.

The Purse of the Heart, called of the Grecians *Pericardium*, of the Latines *Cordis involu- crum* and *Capsula*, *Camera*, or *Aula Cordis*, *Hippocrates* in his Booke *de Corde*, calleth *Culeus*. It is a large Membrane, couering and encompassing all the heart; and carrieth his Pyramidal Figure [Tab. 4. figure 1. D E F] or rather is like a pine Apple, hauing a broad *Basis* aboue, and ending by degrees in an obtuse angle. [Tab. 4. figure 1. F] This is placed in the midst of the double *Mediastinum*, and is embraced by it on either side, to which it groweth round about by the mediation of many Fibres. It is also tied before to the *Pleura*, where the Gristles of the sixt and seauenth ribs on the leste side are ioyned to the Membranes of the *Mediastinum*, where they part or gape from the brest-bone; behinde to the spine of the backe; below to the sinewy circle [Table. 4. figure 1, from E to G] or Tendon of the Midriffe his point [Tab. 4. fig. 1, F] doth so strongly adhere especially on the left, as also on the right [Tab. 4. Fig. 1, Q] side that it cannot be separated without tearing it asunder, and this Connexion is peculiar onely to man. For in other creatures as Dogges and Apes, it standeth off from the Midriffe and is not tyed to it.

The Originall [Table. 4. fig. 1, B. fig. 2. A] of this Membrane at this *Basis* is large, produced from the coats which the *Pleura* affoordeth vnto the foure vesselles which yssue out of the heart; for these vesselles in all that distance which is betweene the *Basis* or broad end of the heart and this *Pericardium*, haue not the common coate from the *Pleura*, because it is employed in the frame of the *Pericardium*.

His substance both for thicknes and strength (as *Galen* sayth in the first chap. of his 6. booke *de usu partium*) is very proportionate; if it had been harder then it is, it would haue offended the Lungs by pressing them; if softer, it selfe might haue bine pained by the bones: for as his position is betweene two contraries, so is his substance middle betweene two extremes.

For

For it is so much softer then a bone, as it is harder then the Lungs; but indeed the *Pericardium* toucheth not the Lungs but by the interposition of the *Mediastinum*, least they should hinder one another in their motion, alwaies I except the fore part of the brest-bone, where the membranes of the *Mediastinum* stand off one from another.

This purse is hard, because of the continuall motion of the heart; on the outside fibrous, within smooth and slippery, that the heart might mooue more freely in it, but on neither side hath it any fat, although *Aristotle* saith otherwise, whom *Vesalius* imagined to be deceived by taking for it the Membranes of the *Mediastinum*, which are indeed sometimes fat as we haue said.

It is tied at the *Basis* of the heart, which is at the 5. rackbone of the Chest, to the vessels which come thence [tab. 4. fig. 1. B, fig. 2. A] which also it bolstereth; but to the body of the heart it is not tyed but is as farre from it at the *Basis*, the point and the sides [tab. 4. fig. 2. BB sheweth the *Pericardium* bent backe to the sides] as is sufficient for the dilatation of the heart, and for the ferous humor heerein contained. Wherefore it is on euery side a little distant from it; which distance if it had beene larger it would haue taken vp too much of the cavity of the chest, and so haue bin a hinderance to Respiration.

It is continuall or whole round about except in the *basis*, where it hath at the last five perforations for the entrance of the hollow veine [tab. 4. fig. 1. A, fig. 2. F] and for his egressse, as also to let out the Arteriall veine, [tab. 4. fig. 2. G] the venall Artery, and the great Artery. [Table 4. fig. 2. H.]

His Connexions.

His perforations.

Table 4. Figure 1. sheweth the heart included within his purse or *Pericardium*, together with the Lungs and a part of the *Midriff*.

Figure 2. sheweth the *Pericardium* opened, and so the situation of the hart and particularly the fore part thereof.

K, The top of the left eare.

L, The coronary or crown-veine and artery of the heart.

LL, Certaine branches proceeding from these vessels.

M N O P, The foure Lobes of the Lungs.

Q, A part of the Midriff.

His vessels.

It receiveth very smal veins [*tab. 4. fig. 1. C.*] and threddy, partly from those that are sent to the *mediastinum*, partly from the veins called *Phrenica* where they are ioined to the midriffe; some say it hath a smal branch from the *Axillary* veine which they cal the *Capsulary* or purse-branch, though *Laurentius* will haue it to come from the *subclavian* Veine. It hath no Arteries vnlesse they be exceeding small, because being so neere vnto the heart it may receiue vitall spirits at hand from it. His nerues are very smal & sometimes scarcely sensible, but from the left branch of the Recurrent sinew to giue him sence.

His vses.

His vse is to be as a habitation and shelter for the heart or as a mantle to couer it, and being of all membranes (except the *dura mater* of the Braine) the strongest, it keepeth it also from pressure that his motion be not impeached, and that it touch not the hard bone. Moreouer it containeth a serous humor whereof we will speake in the next place, and serueth in stead of a ligament together with the helpe of the membranes of the *mediastinum* to reteine the heart in his right seate. *Galen* in the 13. Chapter of his 7. Booke *de Anatomicis Admin.* telleth a strange story of a childe whose breast-bone was cut out, and this *Pericardium* rotted part of it off, and yet the child recovered.

sels.That it is part
of our drinke.That it is
found in liuing
bodies.
But more in
dead and why.In found bo-
dies as well as
in diseased.
The example
of our Sauror.

The vses of it.

In this purse there is contained a watery humor as *Galen* calleth it, carrying the forme of v-rine: wherefore the diuine senior *Hippocrates* who in his Book *de Corde* calleth it *urina*, saith that the heart dwels in a Bladder, yet this water hath no acrimony or saltnesse in it. It springeth partly from a humour which typeth out of the vessels (I meane the veines and arteries of the heart) which the heart as *Hippocrates* speaketh drinketh in, licking vp withall the drinke of the Lungs and pisseth it out againe (for the watery humor is by the high feruour of the heart driuen forth, as we see in greene wood when it is burnt) partly of a portion of the drinke which soaketh in the passage through the sides of the weazon, as it were a deaw and falleth downe hither, and from hence some of it into the venall arteries. The first is proued by the cure of the palpitation of the heart which is caused of the aboundance or ouerplus of this humour, which is turned sayth *Galen* in the second Chapter of his fift Booke *De locis affectis* by blood letting; when together with the blood the serous humor is let out which before fell into the *Pericardium*.

The latter is euicted by an example propounded by *Hippocrates*, for sayth he, if you giue a Pigge that is very dry water mingled with *Minium* or vermillion and presently stick it, you shall finde all his winde-pipes along dyed with this coloured drink; some would haue it to be generated from moyst vapours and exhalations rayled from the humors of the heart, and driuen forth by his perpetual motion and high heate vnto the *Pericardium*, by whose density they are turned into water: and of that opinion are *Falopius*, *Laurentius* and *Archangelus*; who remembreth fixe opinions concerning the matter of it, which we shall hereafter make mention of.

This humor is found not onely in dead bodies as some would, but also in liuing, but more plentifull after death (except in those that dye of consumptions in whome it is little and yellowish) because the many spirits which are about the heart, the body being cold are turned into water euen as those vapors which are raised from the earth are by the coldnes of the middle region of the ayre conuerted into water: we also affirme that it must of necessity be in liuing bodies, and not only in those that are diseased, as they that are troubled with palpitation of the heart, but also in all sound bodies; yet in some more plentifull in others more sparing, but in all moderate; because if it be consumed there followeth a consumption, if it be abundant palpitation of the heart, and if it be so much that it hinder the dilatation of the hart, then followeth suffocation and death it selfe. That it is in liuing bodies may bee proued by the testimony of *Hippocrates* in his Book of the heart, where he saith there is a litle humor like vnto vrine, as also by the example of our Sauror out of whose precious side issued water and blood. It appeareth also by the dissection of liuing creatures which euery yeere is performed for further aduertisement, especially a sheep or such like great with young; *Vesalius* addeth an example of a man whose heart was taken out of his body whilest he liued at *Padua* in *Italy*. Finally the vse and necessity of it doth euict the same.

For the vse of it is to keepe moyst the Heart and his vessels; a hot part the Heart is, so as the left ventricle will euen scald a mans finger if it be put into it, and so continually moued that vnlesse it were thus tempered it would gather a very torrifying heate; by cooling it also keepeth it fresh and flourishing. It moystneth also the *Pericardium* wherein it is contained, which otherwise by the great heate of the heart would be exicated or dried vp. By it also the motion of the heart becommeth more facile and easy, and this motion spendeth it and resolueth it insensibly

sensibly by the pores as it is bred; but if in the passage it be stayed, then saith *Varolius* are there many hairs found growing right against it on the brest. Finally, it taketh away the sense or feeling of the waight of the heart, because the heart swimmeth as it were in it, euen as we see the Infant swimme in sweate in the wombe, as well to take away the sense of the waight of so great a burthen from the Mother, as also that it might not fall hard to any part in her body; you may adde to this if you please, that it helpeth foward the concretion of the fat about the heart.

The cause of hairs vpon the brest.

In the cavity also of the Chest there is found such a like water mingled with blood with which the parts of the chest are continually moistned and cooled. And thus much of these circumstances of the heart. Now follow the Vessels of the chest.

Another water and blood mingled in the Chest.

CHAP. IX.

Of the ascending trunk of the Hollow veine.

The trunk of the Hollow veine hauing perforated the *Diaphragma* or Midriffe, [tab. 5. fig. 1. from A to D, tab. 6. from B to H] runneth along the Chest as high as the *Patel-* bones before it be diuided. It is greater then the descending trunk, because it is to

Table 5. Figure 1. sheweth the diuision of the Hollow veine in the *Iugulum* or hollow under the *Patel-* bones. On the right side is sheweth how it is commonly beleued to be diuided into two trunks, the one called the *Sub-Clauius*, the other *Super-Clauius*, from whence came that scrupulous choise of the *Cephalica* and *Basilica* Veines in *Phlebotomy* or blood letting. On the right side is shewed how the tranke is but one, out of which both the foresaid veines of the arme do proceede.

Fig. 2. sheweth a portion of the Hollow veine as much as ascendeth out of the right ventricle of the heart vnto the *Iugulum*, wherein is exhibited the nature of the Fibres which are in the bodies of the veines.

TABVLA V.

FIG. IV.

- AA, The trunk of the hollow veine from the heart to the *Iugulum* or Sticking-place.
- B, The Coronary veine of the heart.
- C, The veine *Azygos* or fine part.
- dd, The branches of the fore saide veine called *Intercoastales inferiores*.
- D, The diuision of the hollow vein in the *Iugula*.
- EE, The *Mammary* veines.
- F, The vpper *Intercoastall* veine.
- G, The veine called *Subclauia*.
- HH, The *Cephalica* or head veine yssuing therefrom.
- II, The veine called *Hepatica* or the *Liuier* veine issuing also from the *Subclavian* tranke marked with G.
- KK, The internall *jugular* veine.
- LL, The externall *jugular* veine.
- M, The *Subclavian* veine, out of which issucth the right *Liuier* veine at Q.
- N, The *Superclavian* veine out of which issucth the right head veine at P.
- OO, The veines called *Cernicales* or neck veines.
- Q, the *Hepatica* or *Liuier* veine.
- P, The *Cephalica* or Head veine.

The second Figure.

- AA, The trunk of the Hollow-veine.
- B, The veine *Azygos* or the vnated veine.
- C, The diuision of the hollow vein in the *Iugulum* on either side into two branches as it is commonly receiued.
- DD, The *subclavian* branches.
- EE, The *superclavian* branches.
- FF, The externall *jugular* veines.
- GG, The internall *jugular* veines.

Figure 3. sheweth a rude delineation of the Fibres in the bodies of the veines.

A, The transuerse or ouerthwart Fibres. BC, The oblique or slope fibres of each kind. D, The right fibres. E, The implication or texture of the 3. kinds of Fibres.

Figure 4. sheweth the distribution of the veine *Azygos*, which we shall shew more distinctly in the 7. Table.

A, A part of the trunk of the hollow veine. B, The originall of the veine *Azygos*. C, O, The diuision of the same vnated vein at the eight rib. D D D D, The right and left *intercoastall* veines.

conuay bloud to more parts, it hath also vnder it the *thymus* or sweet-bread, that thereby being bouldered it might more safely be diuided.

Before the diuision it sendeth out foure branches.

The first is called *Phrenica* [tab. 6. C] or the veine of the Midriffe, one on each side, which diuersly are disseminated through the Midriffe, and beside it transmitteth branches to the *Pericardium* and the *Mediastinum*: the right issueth out of the trunk sometimes in the chest, the left alwaies vnder the Midriffe: then the trunk of the hollow veine perforateth the *Pericardium* and inclining a little to the left hand [tab. 6. above B] degenerateth into the right eare of the heart [tab. 6. D] and is fastned into the right ventricle of the heart into which as into a Cisterne it powreth his blood. The second is called *Coronaria cordis* [tab. 5, fig. 2, B, tab. 6, E] the

Table 6. sheweth the trunk and branches of the hollow vein as they are disseminated through all the three Regions of the body.

TABVLA VI.

aa, the veine called *Cephalica* or the vter veine of the arme. bb, the veine called *Muscula superior*. dd, A veine climbing to the top of the shoulder which is sometimes double. mm, The veine called *Basilica*. z, the trunk of the hollow veine vnder the Liuer. x, the right fatty veine or *Adiposa dextra*. n, the left fatty veine or *Adiposa sinistra*. o, the emulgent veines. lll, the right and left spermatike veines. r, the beginning of the vessell called *Vas vasicosum* or the bodden vessell. s, the veines called *Lumbares* or belonging to the loynes. a, the bifurcation of the hollow veine into the *Iliack* branches. p, the vpper veine called *Muscula*. ps, A diuision of the left *Iliack* branch into an *Interior* marked with p, and an exterior marked with r. r, the veine called *Muscula media*. q, the veine called *Sacra*. v, the veine called *Hypogastrica* which is a branch of the inner bow marked with v, descending to the bladder and the wombe. w, A veine proceeding out of the externall branch marked with v, which is ioyned to the small branches of the inner veine not far from the perforation or hole of the share-bone. t, the veine called *Epigastrica* which is an exterior shoot of the branch s, rising vpperward. Δ, the veine called *pubenda*, an interior shoot of the branch s, going to the genitals. θ, the first skin-veine of the leg descending to the toes of the feete. λ, A branch offered to the place of the groyn or lesk. Σ, A branch creeping through the skin of the thigh. Ω, the veine called *Muscula inferior*, creeping through the place where the hip is articulated or ioyned with the thigh. 1, A veine distributed to the 7. and 9. muscles of the leg. 3, A veine conueyed to the sixt muscle of the thigh.

A, The trunk of the hollow veine below the Liuer.

aa, The roots of the same hollow veine proceeding out of the Liuer, which make the trunk thereof.

B, Another root arising out of the hollow side of the Liuer.

B, The seate of the hollow veine betwixt the Liuer and Midriffe.

C, The veine *Phrenica* or the veine of the Midriffe.

D, The orifice by which the Hollow veine groweth to the heart.

E, The crown-veine of the heart.

FF, The trunk of the veine *Azygos*.

GG, The *Intercostall* veines proceeding from the foresaide trunk.

H, The by-partition of the trunk of the hollow veine at the *Inguinum* or sticking place.

II, The *Subclavian* veine tending to the arme.

K, The vpper *Intercostall* veine.

LL, The *Mammary* veines descending.

Mr, The coniunction of the descending *Mammary* veine at M, with the *Epigastricall* veine at r.

NN, The necke veine called *Cervicalis*.

O, The veine called *Muscula*.

PP, The vpper chest veine.

Q, The double *Scapular*, or the veines of the shoulder-blade.

RR, The lower chest veine.

SS, The internall *Iugular* veine.

TT, The externall *Iugular* veine.

V, the externall *Iugular* veine diuided into two vnder the root of the eare.

X, the inner branch thereof.

Y, the outer branch thereof.

Z, A branch proceeding from the vter veine next about named, to the face.

a, the fore-head veine.

α, A branch creeping vp the temples.

* A sacle reaching to the nowle or back-side of the head.

crowne veine of the heart, because like a crowne it compasseth the Basis of the heart. This disperseth many branches through the outward surface of the heart even to the Cone or point thereof, especially on the left side, because the substance of it there is thickest and therefore needeth more Aliment.

Afterward the Hollow-veine perforateth the *Pericardium* againe, and againe groweth round but much lesse then before, and riseth vp where the right Lung is parted from the left, and so passeth to the *Iugulum*, but about the heart in the midst of the body it parteth with a notable trunk or branch to be distributed to the Spondels and the spaces between the ribs.

And this is the third branch called *Vena azygos*, or *sine pari*, that is, the vn-mated vein which we haue before called *non-pari* [tab. 5, Fig. 1, C, Fig. 2, B, Fig. 4, B] because commonly in a man it is but one, as also in dogs, and hath not another on the other side like vnto it.

It ariseth out of the backward and lower side of the hollow veine [tab. 5, Fig. 4, A] about the heart, between the fourth and fift spondell of the Chest, but more toward the right side then toward the left. In those creatures that chew the cud it is double, as also in some men (haply in those that we call *Ambidexters*, that can vse both hands alike) but very rarely, yet *Falopius* hath worthily obserued, that there is in men a left branch which doth the office of the *Vena sine pari* [tab. 7, 1], arising from the left *Subclavian* branch, and affoordeth branches to some of the distances between the ribbes. Sometimes it ariseth not out of the *Subclavian* branch,

Why some men are ambidexters. *Falopius*.

Although it shew the Trunke of the Hollow-veine disseminated thorough both the Bellies, notwithstanding it serueth especially to exhibit the distribution of the veine *Azygos*, and the coniunction of the branches thereof with the veines of the Chest, which heere is onely shewed on the right side.

TABVLA VII.

aa, The Hollow-veine from the *Iugulum* to the holy bone.

bb, The diuision of the Hollow-veine into the Iliack branches.

cc, The diuision of the hollow vein at the *Iugulum* on both sides into the *Subclavian* branches.

dd, The trunk of the veine *Azygos* which insinuateth it selfe into a branch of the hollow veine at .

ee, f, A left branch from the veine *Azygos*, inserted into the emulgent veine at f.

gg, The Kidnies.

hh, The Vreters.

i, The left vpper intercostall veine.

l, The right descending Mammary veine.

m, The internall iugular veine.

n, the externall iugular veine.

o, The veine *Muscula* going to the Muscles of the necke.

p, The diuision of the *Subclavian* branch into the *Cephalica* and *Basilica* veines.

qqq, The *Cephalica* veine cald also *humeraria*.

rrr, The *Basilica* veine, which some also call *Axillaris*.

s, The vpper Chest-veine called *Thoracica*.

tt, The lower Chest-veine going to the outward Muscles of the Chest.

u, A branch of the *Cephalica* veine deriued vnto the Muscles that lift vp the arme and to the skin thereabout before it passe vnder the shoulder.

xxxx, Certain veines in the Chest from the *Azygos*, which are vnited with the outward branches yssuing from the exterior Chest-veine, which is deriued out of the *Basilica*.

yyy, The outward veines of the Chest which are vnited with the inner branches of the *Azygos*. x, A branch of the *Basilica*, which is ioyned with the *Cephalica*. A. A branch of the *Cephalica*, which is ioyned with the *Basilica*. z, B, The veine called *Mediana* or the middle veine.

but out of the trunk of the hollow veine neere the third Spondell of the Chest before the diuision thereof.

The branches of
Vena sine pari.

Commonly from the trunk of the veine *αὐγος* [tab. 5, fig. 4, B, tab. 6, FF, tab. 7, d] out of the backside of it as well on the left hand as on the right, but on the right especially, branches are distributed to the distances, sometimes of al but most what of the ten lower ribs, [tab. 5, fig. 4,] which are called *Intercoales rami* [tab. 6, GG] branches between the ribs. This vein also without his mate, affordeth many furcles to the Gullet, and sometimes neere the fourth Spondell of the Chest it sendeth a branch vppward [tab. 7, at the vpper d] from which are deriued furcles to the foure vpper ribs.

The Interco-
stall branches.

The Intercoastall branches also yeelde small strings of vessels [tab. 7, xxx] which yssue out of the chest, which are inoculated with furcles of the veine called *Thoracica inferior*, [tab. 7, yy] whence it is that we with good successe in Pleurifies open the Internall Veine of the affected side.

The diuision
of Vena
αὐγος.

The trunk of the *αὐγος* at the 8. or 9. rib is aboue the spine diuided into a right branch and a left [tab. 5, CO] which both passe downward. The left which is the larger determineth into the middle of the emulgent. The right is ioyned to the hollow veine aboue the emulgent to the emulgent more rarely, most commonly it is implanted into the last veine of the Loynes, [tab. 7, *] and hence it is that in the beginning of the Pleurifie it is profitable to open the veine in the ham or in the foote.

*Intercoastalis
superior.*

The fourth is that veine we call *Intercoastalis superior*, or the vpper Intercoastall veine [tab. 5, fig. 1, F, tab. 6, K] on each side one, arising from the *Subclavian* branch about the beginning of the Iugular veins [tab. 6, ST] and reflected vnder the Artery of the arme, and is diuided into two branches especially on the right side, which are distributed to the distances of the two vppermost ribs, sometimes to the three vppermost, and are ioyned with the Mammary branches which creepe along the gristles. [tab. 6, LL] But this veine is sometimes wanting, that is, when the vein *αὐγος* affordeth branches to al the ribs, as we said euen now that sometimes it did. Also from all the Intercoastall veins there are small tendrils which passe into the holes of the racke-bones for their nourishment, as also for the nourishment of the spinall Marrow.

The ascending
trunke.

The trunk [tab. 6, H] ascending is sustained by the Sweete-bread [tab. 3, F] and diuided into two notable branches [tab. 6, LL, tab. 7, CC] one tending to the right hand, the other to the left, these as long as they are within the Chest, are called *Rami subclauij*, because they are vnder the Patell-bones, which they call *Claues*. From each of these *Subclavian* branches, some veins spring out of their vpper part, some out of their neather part. From the lower part before the *Subclavian* branch is diuided doe yssue foure boughs.

*Mammaria
inferior.*

The first is called *Mammaria descendens* [tab. 5, fig. 1, EE, tab. 6, LL, tab. 7, I] the descending pap-veine.

Mediastina.

The second *Mediastina* [tab. 2, Q] because it is Disseminated especially through the *Mediastinum*.

Cervicalis.

The third *Cervicalis* or the necke-veine [tab. 5, OO, tab. 6, NN] because it communicateth furcles to the Marrow contained in the rack-bones of the necke.

Muscula infer.

The fourth *Muscula inferior* [tab. 6, O] because it is distributed into the vpper Muscles of the brest, and the lower Muscles of the necke.

The Axillarie
veine.

When the *subclavian* veine attaineth out of the Chest [tab. 7, P] it is called no more *subclavia* but *Axillaris*, because it is come to the arme-hole called *Axilla*. The Axillary veine therefore before it be diuided sendeth out two propagations.

Scapul. interna

The first is called *Scapularis interna* [tab. 6, Q] because it is dispersed to the Muscles on the inside of the *Scapula* or shoulder-blade.

*Scapul. externa
Cephalica.*

The second *Scapularis externa* [tab. 6, d] is diuided to the outside of the blade. Afterward the Axillarie veine is diuided into two branches, [Tab. 5, HL, tab. 6, a m, tab. 8, q r] the vpper of which is called *Cephalica* [tab. 6, a, tab. 7, q] the lower *Basilica*. [tab. 6, m, tab. 7, r]

*Basilica.
Thoracica sup.*

From the trunk of the *Basilica* issue two veins. The first called *Thoracica superior* [tab. 6, PP, tab. 7, f] because it is distributed into the skin and Muscles which couer the chest.

Thoracica infe.

The second *Thoracica inferior* [tab. 6, RR, tab. 7, ti] because it runneth along the side of the chest, and the branches of this veine are inoculated [tab. 7, yy] with the furcles of the Veine *αὐγος*. [tab. 7, xxx]

Muscula supe.

From the vpper part of the *Subclavian* veine three veins doe arise.

The first is called *Muscula superior* [tab. 7, o tab. 6, bb] because it is distributed into the muscles and skin on the backside of the necke.

The

The second *Inguularis externa* [tab. 5, fig. 1, LL, tab. 6, TT, tab. 7, n] is commonly on each side one, but sometimes double, and is againe diuided vnder the root of the eare.

The third *Inguularis interna* [tab. 5, fig. 1, KK, tab. 6, T T, tab. 7, m] is greater in a man then it is proportionably in other creatures, because a mans braine is greater; iust at the head it is diuided.

But because al these veines we must handle more accurately in our Book of the vessels, it shal bee sufficient here onely to haue named them and shewed them vnto you, wee proceed to the Nerves.

CHAP. X.

Of the Nerves in the Chest and the Necke.

THe Nerves disseminated through the Chest and the Necke are of two sorts, yet all proceeding from the marrow of the braine; the first sort whilest the marrow is in the skul, the other after it is in the racke bone, and is called *spinalis medulla*.

Out of the marrow yet in the skul, the sixt paire come. [tab. 8, fig. 1, ee] They seeme to be but one nerue, but indeed are two inuested with one membrane, and passe out at a hole betweene the nowle and the temporall bones. The *anterior* and lesser part of this nerue is disseminated into the muscles of the tongue and into the mouth. The *posterior* and greater sendeth branches to the muscles of the neck, [tab. 8, fig. 1, f] to the second moouing the shoulder blade, and descending more inward to the muscles that are in the cavity of the *larynx* or throtle [tab. 8, fig. 1, q] some slender ones also to the muscles of the bone *Hyois*.

Above the *Inguilum* or Region of the Coller-bone before it enter into the Chest, this branch is diuided into two [tab. 8, fig. 1, b] boughes, the one outward and the greater, the other inner and the lesse.

The outward bough maketh the recurrent nerves, found out first by *Galen*. They are also called the voell nerves, because if they be wounded, the creature loseth his voyce as we haue often tryed in the dissection of liuing Dogs, for if one be cut or tyed he loseth halfe his voyce, if both, he loseth it wholly.

The outward branch of the right nerue presently after the diuision [tab. 8, fig. 1, b] sendeth furcles on both sides [tab. 8, fig. 1, KK] to the muscles arising from the brest-bone and the *Clauicles* or coller-bones; and presently when it commeth to the *Axillary* artery [tab. 8, fig. 2, P] it transmitteth as it were about an Axle-tree [tab. 8, fig. 2, P] three branches from the inner side [tab. 8, fig. 1, l] which being reflected toward the head and vnited do make the right recurrent; [tab. 8, fig. 2, Q Q and fig. 1, m] and it is inserted with the left into the second gristle of the *larynx* [tab. 8, fig. 1, n] and implanted into the *glottis* and the muscles of the *larynx*.

The foresaid branch after it hath made the recurrent nerue, descendeth obliquely vnder the coller-bone, and in the way outwardly affordeth furcles to the *pleura* [tab. 8, fig. 1, qq] & to the coat of the lungs, inwardly to the *Pericardium* or purse of the heart [tab. 8, fig. 1, t] and to the heart it selfe, and then maketh the nerue called *Stomachicus dexter* or [tab. 8, fig. 1, se] the right Stomacke nerue which reacheth ouer to the left side, as the left doth to the right side, and so at length is consumed into the left orifice of the Stomacke, whence it hath his denomination.

The inward branch of the right nerue is called *Costalis* [tab. 8, fig. 1, iiz] which affordeth branches to all the bowels of the lower belly, and reacheth as far as the holy-bone, and is distributed into three branches.

The first [tab. 8, fig. y] creepeth to the lower membrane of the kell, & is subdivided into three small branches, whereof one goeth to the collick gut [tab. 8, fig. 1, z] and this is the reason that after a long fit of the collicke men grow hoarse; another [tab. 8, fig. 1, a] to the beginning of the guts which is so small, that it can hardly be perceiued. The third affordeth furcles [tab. 8, fig. 1, s] to the bottome of the stomacke: on the right side thereof, and to the vpper membrane of the kell, the rest of it is spent in the coat of the Liuer [tab. 8, fig. 1, v] and the bladder of gall. The second and the lower [tab. 8, fig. 1, d] reacheth to the right kidney, and hence it is that men vomit in fits of the stone.

The third which is the greatest [tab. 8, fig. 1, e] passeth to the Mesentery and the guts. The rest descendeth directly to the bladder. [tab. 8, fig. 1, s]

Inguularis externa

Inguularis interna

The sixt paire of sinewes.

The recurrent nerves.

The right nerue of the 6. coniugation.

Stomachicus dexter.

Costalis hath 3 branches.

The

Table 8. Figure 1. sheweth the Braine and the after-Braine or Cerebellum together with the Nerves (as the common opinion is) proceeding out of them: and this Table we have especially set in this place to shew the distribution of the Nerves of the sixth coniugation through both the bellies.

A, The Braine.
 B, The Cerebellum or after-braine.
 C, A proesse of the braine, but not that which is called *Mammillaris*.
 DD, The marrow of the back as it is yet within the skul.
 E, The *Mammillary* proesse or instrument of smelling.
 F, The opticke nerve. (spread.
 G, The coate of the eye into which the opticke nerve is
 H, The nerve that moveth the eye or the second payre.
 I, The third coniugation, or the harder & lesser branch
 of the nerves of the 3. coniugation brought forward.
 K, The fourth coniugation or the greater and thicker
 nerve of the third payre bending downward.
 L, A branch of the nerve marked with I, which goeth
 to the fore-head. (iaw.
 M, Another brāch of the nerve I, reaching to the vpper
 NN, A nerve proceeding from the branch I, intexed
 or wouen with the coate of the nose.
 O, The nerve of the temporall muscle issuing from the
 P, A nerve contorted of the nerves K, & b. (branch I.
 Q, A nerve proceeding from the branch K, to the soc-
 cets of the vpper teeth.
 R, A nerve creeping from the nerve K, to the lower iaw.
 S, A surcle of the branch R, offered to the lower lip.
 TT, Other surcles from the branch R, attaining to the
 lower teeth.
 VV, A branch of the nerve K, diffused into the coate of
 the tongue.
 XX, The fourth paire of sinews which goe into the coat
 of the pallat.
 Y, the 5. paire of sinews which are the nerves of hearing
 a, the membrane of the eare, vnto which that fift nerve
 goeth.
 bc, two small branches of the fift coniugation vnting
 themselves with the nerve P.
 d, the eight coniugation or a nerve of the fift paire at-
 taining vnto the face.

ee, the sixt paire of nerves. f, A branch from the nerve e, reaching to the muscles of the neck. g, Small branches deriued vnto
 the throtle or larynx. h, the byfurcation of the nerve into two branches. iii, An inner branch hanging to the rack-bones,
 and strengthening the *intercostall* nerves, and is therefore called *Intercostalis*. kk, Surcles of the viter branch going to the heads
 of the muscles, to the breast-bone and to the collar-bones. lm, branches of the right nerve I, making the right Recurrent
 nerve. mn, the insertion of the Recurrent sinews into the muscles of the larynx. op, Branches of the left nerve o, making the
 left Recurrent sinew p. qq, Branches from the sixt coniugation going to the coat of the lungs. r, Small nerves of the heart &
 of the purse thereof called the *Pericardium*, as also some approaching to the coates of the lungs. s, nerves on either side sent
 to the stomack. t, the right stomacke nerve going to the left orifice of the stomack. uu, the left stomack nerve going to the
 right orifice of the stomack. x, A nerve from the branch u, passing into the hollownes of the liuer. y, the nerve belonging to
 the right side of the kell. z, the nerve belonging to the collick gut. a, A nerve creeping to the gut called *duodenum* and the
 beginning of the *icium* or empty gut. β, A nerve implanted in the right side of the bottome of the stomack. γ, A nerve
 belonging to the Liuer and bladder of gall. δ, A nerve reaching vnto the right kidney. ε, A branch reaching the *Mesente-*
rium and the guts. ζ, A branch sprinkled to the right part of the bladder. η, A branch going through the left part of the kel.
 θ, Surcles deriued to the collick gut and the kell. x, Small branches inserted into the spleene. λλ, A nerve approaching to the
 left side of the bottome of the stomack. μ, A branch belonging to the left side of the *Mesentery* and the guts. ν, A branch
 which attaineth to the left kidney. ξ, Small nerves creeping through the left side of the bladder. o, The 7. paire of sinews. π, A
 branch deriued from the sixt coniugation to the muscles which arise from the proesse called *Styloides*. ρ, A branch of the 7
 coniugation which goeth to the muscles of the tounge, of the bone *hyois*, and of the throtle or larynx. σ, A coniunction or
 coition of the 6. and 7. paire into one nerve.

Figure 2. exhibiteth the Recurrent sinews together with a portion of the great Artery and the rough Artery called the *weaz on*.
 A, The orifice of the great artery cut from the heart. aa, The coronall arteries. BCD, The diuision of the great artery into two
 trunks, the descending C, the ascending D. E, the left *Axillary* artery. F, The right *Axillary* artery. G, the right *Carotis* or slee-
 py artery. H, the left *Carotis*. I, the trunk of the rough artery. KL, the diuision of the rough artery. M, the head of the rough
 artery called the larynx or throtle. NN, Certaine glandules or kernels at the root of it. OO, the right and the left nerves. P, a
 reuolution of small branches of the right nerve to the right axillary artery. QQ, the right Recurrent nerve. R, a reuolution of
 small branches of the left nerve to the descending trunk of the great artery. SS, The left recurrent sinew.

 heart, becau

The left Nerue of the sixt coniugation [tab. 8. fig. 1. e, fig. 2 o] is diuersified after the same manner with the right, and when it attaineth to the collar, is diuided into an outward and an inward branch. The outward communicateth it selfe to the *Pleura* [tab. 8. fig. 1. q] and the coats of the Lungs, and descending to the trunk of the great artery [tab. 8. fig. 1. c] transmitteth commonly three small furcles, which being reflected and vnited [tab. 8. fig. 1. R] make the left recurrent Nerue. [Table 8. fig. 1. ss] The remainder of this outward bough enclining to the right hand maketh the Nerue, which they call *Stomachicum sinistrum*, the left Stomacke Nerue [Table 8. fig. 1. uu] which vnder the gullet is ioyned with the right Stomacke Nerue. [Tab. 8. fig. 1. f]

The left nerue of the 6. coniugation.

The left Recurrent.

The inward bough of the left Nerue passeth through the chest where it maketh *Sinistrum costalem*, the left Rib-nerue, & vnder the Midriffe is diuided into three branches. The first and vppermost [tab. 8. fig. 1. n] goeth to the Kell, from which doe proceede two smal furcles, one to the collicke gut [tab. 8. fig. 1. o] and the lower Membrane of the Kell; [tab. 8. fig. 1. r] the other to the bottome of the stomacke [tab. 8. fig. 1. aa] and the vpper Membrane of the Kell; that branch which remaineth is inserted into the Splene. [tab. 8. fig. 1. x]

His inward bough diuided into three.

2. The second [tab. 8. fig. 1. u] runneth to the left side of the mesentery, and vnto the guts thereabout, and sometimes some furcles there-from accompany the Seminary vessels euen to the Testicles.

3. The third [tab. 8. fig. 1. v] attaineth to the left Kidney: the remainder of the whole branch is consumed in the left side of the bladder. [tab. 8. fig. 1. z]

And thus much of the diuication or distribution of the Nerues from the sixt coniugation which yssue from the marrow of the braine contained within the scull.

The Nerues that yssue out of the marrow of the braine after it is contained in the Spondels of the backe, and is commonly called *Spinalis medulla* are of two sorts, some of the Necke, others of the chest.

Two sorts of Nerues.

Of the Nerues of the Necke there are seuen pairs, and from the three last proceedeth one branch called the Midriffe-Nerue, made of three furcles all dispersed into the *Diaphragma* or Midriffe.

Cervicales pairs seuen.

Of the Nerues of the chest there are 12. paire called *Intercostrales Nervi*, because they pertain to euery distinction between the ribs, & runne close to the bone on the lower side thereof all along the length of it, for in the bottome of the rib there is a cavity where the Artery Vein and Nerue doe meete; and therefore when you shall open a mans side diseased of the *Empyema*, you must make your incision at the vpper part of the Rib.

Thoracice pairs 12.

A note how to make incision in the *Empyema*.

And this shall suffice to haue spoken of the Nerues belonging to the Chest at this time and in this place, the more accurate Discourse you must looke for in our Booke of the Vessels.

CHAP. XI.

Of the Heart.

He Heart is a principall part; not as *Aristotle* called it principall, who placed in it all the actions of life and sense; but as being the fountaine of the Vitall Faculty and spirit, the place and nourishment of naturall heat, whereby the naturall heate of all the parts is preserved, and by his influence repaired; the seate of the Irascible or angry part of the soule, the root of the Arteries and Author of the Pulse.

It is called *Cor à currendo*, because it seemeth continually to run, for that it is continually moued. The Greekes call it *καρδιά*, either of a word which signifieth to beate or pante, which is our proper word for the beating of the heart; or from a word which signifieth a Bakers moulding-board, because in it the alimentary blood is as it were kneded, wrought, moulded, and driuen out into thinnesse, till it turne into a vitall spirit; or finally from a word which signifieth principality, because it is a principall part as well as the braine; yet so that as the Braine is of greater dignity, so the heart is of greater necessity; for the least hurt of this most what causeth death; and *Galen* saith, that death neuer happeneth but when the heart is immoderately distempered. Whereupon also *Aristotle* saith, There was neuer any liuing creature seene without a heart, because without it there can be no Originall at all of heate.

Names.

The necessity of the Heart.

Is

It is situated in the midst of the cavity of the chest in a Noble place as it were a Prince; and after the manner of those which being but one do occupy the midst as well for security, as that the body may be equally ballanced. At the fifth rib it is embraced by the Lobes of the Lungs as it were with fingers [tab. 3. NOPQ: Tab. 9, fig. 1, and 2, tab. 10, fig. 1, and 2,] round about, that equally out of all the Lungs, it might draw breath by the venall Artery, and might againe deliuer ouer and diffuse blood by the arteriall veine, and life and heat by the great Artery to all the outward parts; and it is locked vp in his owne Capcase [tab. 9, fig. 1, DEF: Fig. 2, BB] but so that the Basis resteth exactly in the midst, whether we regard the right hand or the left, the fore-part or the back, the vpper or the lower; but the point [tab. 9, fig. 2, E] reacheth to the left hand, yet forward as farre as the left Nipple, so that in a liuing man it looketh directly forward (with a kinde of strutting position) to the Gristles of the sixth and seventh ribs of the left side where they are ioined to the brestbone, that it may the better warme the fore-part against which we moue. And truly it behoued that it should encline to one side that it might giue way to the Midriffe, and so neither of their motions (which are both perpetuall) should be hindred; but not vnto the right side, for that the hollow veine takes vp as he ascendeth thorough the chest; happily also Nature was heere of *Aristotles* minde in the 4. Chapter of his 3. Booke *de partibus Animalium* (for he was often of hers) that the left side was the colder and therefore she placed this hot part in it; for on the right are the hollow veine and the *Non-paril*, which heate it sufficiently; and so both sides are provided of heate and strength alike. Notwithstanding the common people are deceiued, who thinke it lyeth wholly on the left side because the motion and pulsation is most felt on that side, when indeede it lyeth in the verie midst, as in the more Noble place; but the left ventricle which is the Store-house of spirits and the great Artery were the cause of their error, as *Galen* sayth in the second Chap. of his first Booke *de usu partium*. Adde heereto, that in dead carkasses it is drawne somewhat to the left side, partly by his owne waight, partly by the waight of the great artery which is fastned vnto it.

His connexion It is tied by the mediation of the *Pericardium* or purse to the *Mediastinum* [tab. 9, fig. 1, from F to G] and to the Midriffe, as also by his vessels to other parts. For *Galen* saith, that principals in some things are to be tyed together, and communicate one with another: otherwise it is loose, that it may mooue the more freely.

His Figure: The figure of it as *Hippocrates* saith in his Booke *de Corde* is *Pyramidall*, [expressed so in the table 9, fig. 2,] or rather turbinated & somewhat answering to the proportion of a Pine Apple, because a man is broad and short chested. For the Basis aboue [tab. 9, fig. 2, CD] is large and circular but not exactly round, and after it by degrees endeth [tab. 9, fig. 2, E] in a cone or dull and blunt round point; for such a figure was fittest for his function, because length maketh much for traction or drawing, and roundnes for amplitude and strength: so in great dilatations it is sphericall that it might hold more; and in his contractions long and as it were *Pyramidall*, especially in brute beasts.

The names of the Basis. His superior part which is called the basis, the head, and the roote [tab. 9, fig. 2, CD] is broader because of the vessels which in that place haue ingate and outgate, haply also because of his motion, that in this broad Basis the excauations or cauities might be the larger, that when it is contracted both kindes of Blood arteriall and venall might haue place and room to retire to, and not be too vehemently wrought or pent vp in too straight a roome, least it should violate the continuity of his substance or of the fibres therein.

The names of the lower end. His lower part is called the *Vertex* or top, *Mucro* or point, the *Cone*, the height of the heart. *Hippocrates* calleth it the taile [tab. 4, fig. 2, E] which *Galen* saith in the 7. chapter of his 6. Booke *de usu partium* is the basest part, as the Basis is the noblest. Before the heart is gibbous or bunched, behind hollow and in the sides prominent. The Superficies or surface of it is smooth and polished all ouer, were it not that in some places the Fat, in other the Coronary vessels strutting with blood, did make it vnequall.

His quantity or magnitude. His quantity or magnitude is not alike in all, and in a man proportionably (as also the braine and the liuer) greater then in other creatures being as long as the breadth of 6. fingers and foure broad, and so many high. But in fearefull creatures as the Hare, Hinde, Ass and such like it is proportionably very great, for the heat when it hath too much scope or roomth (saith *Aristotle*) is easily dissipated and vanisheth.

The parts of the Heart. Externall. The parts of the Heart are some externall, others internall. The externall are the Purse, of which wee haue already spoken, the coate, the fat, the vessels which are of two sorts, some which encompass the Heart, others which reach vnto the entrances into his Ventracles and the

the ears. The in

the eares. The inward parts are the fleshy substance and the Fibres, the Ventricles and the Values or Flood-gates.

The coate is proper to the heart, very thin and fine. *Vesalius* likens it to the Membrane that compasseth the Muscles, this inuesteth it as that of the Muscles, and so strengtheneth his substance from which it cannot be seuered. The fat called *Pinguedo* with *Columbus*, or *Adeps* with *Galen* and *Aristotle* or both with *Archangelus*, very plentifully gathered about it like Glue, especially at the Basis where the greater vessels are placed, because there is the condition celebrated of those things that are contained in it, and not in the Cone or point. This fat is harder then it is in any other part; and therefore it should seeme rather to bee *Adeps* then *Pinguedo*, and that is *Galen*s and *Aristotle*s reason; for if it were *Pinguedo* it would melt with the extreame heate of the heart to great disadvantage. Howsoeuer the vse of this Fat is to moysten the heart, least being ouer-heated with his continuall motion it should grow dry and exiccated, but this kinde of fatty humidity is hardly consumed, but remaineth to cherish it, and to annoynt and supple the vessels that they cleaue not with too great heate and drought.

Moreouer, the heart being the fountaine of heate which continually flameth, it serueth for a sufficient and necessary Nutrimment whereby it is cherished and refreshed, and in great affaishments nourished and sustained; least otherwise the heart should too soone depopulate and consume the radicall moysture. Wherefore *Galen* ascribeth this vse to fat, that in great heates, famins, & violent exercises, it should stand at the stake to supply the want of nature at a pinch.

heart commeth
from his nerues

A cause of sud-
den death.

So saith *Auicen*, Fats of all kinds are increased or diminished in the body according to the increase or diminution of heate, wherefore heate, feedeth vpon them. We haue often obserued in opening of the ventricles of the heart, in the very cauities of them a certaine gobbet or morsell if not of Fat yet of a substance very like it, so that we haue more wondred how that should in such a furnace congeale, then the other in the out side. The cone is alwaies moystened by the humor contained in th *Pericardium*.

The vessels of the heart are of all kinds, which doe compass the heart round about. [Table 9. fig. 2. l & branches from these, LL, tab. 10. fig. 2. D] The veine is called *Coronaria* or the crown veine arising from the trunk of the hollow veine [tab. 6. E] before it be inserted into the right ventricle, and sometimes it is double: this engirteth round like a crown the basis of the heart, and hath a valve set to it, least the blood should recoil into the hollow veine.

From this crown veine are sprinkled branches downward along the face of the heart, which on the left side are more and larger, because it is thicker & more solid then the right side. This bringeth good and thicke blood, laboured onely in the Liver to nourish this thicke and solid part, that the Aliment might be proportionable to that it should nourish. By this vessell also it may be beleued that the Naturall Soule residing in the naturall spirit is brought into the heart with all his faculties.

It hath also two arteries called *Coronarias* [tab. 12. fig. 1. BB] proceeding from the descending trunk of the great Artery, which together with the veine are distributed through his substance to cherish his in-bred heate, and supplying vitall spirits doe preserve his life: for if the heart did liue by the spirits perfected in his left ventricle and carried vnto his substance without arteries, then also might the same spirit passe through the pores of the heart and so be lost.

It hath also Nerues but very small ones from the 6. coniugation [tab. 10. fig. 1. K] or from the nerues which are sent vnto the *Pericardium* which are distributed into his *basis* [tab. 10. fig. 2. h] close by the arteriall veine, but not very precious; and as some think for sence onely and not for motion, because his motion is Naturall and not Animall. But saith *Archangelus* if there must be but one and not two principles of motion in vs, then shall the Braine bee also the originall of all motions, because it is the seate of the sensible Soule, (for that opinion of *Aristotles* who attributeth vnto the heart only all the powers and faculties of the soule, *Galen* & the later writers do with one consent disauow) and so this nerue shall minister vnto the heart not onely sence but also motion and both their faculties, and also the faculty of pulsation or the motion of dilatation and constriction. And this nerue sometimes though seldome is suddenly stopped, whence commeth hasty and v unexpected death, which we call sudden death, the faculties of life and pulsation being restrained so that they cannot flow into the heart. But we with *Galen* in the 8. chap. of his 7. Book *de Anatom. Administ.* will determine for our parts, that the faculty of pulsation ariseth out of the body of the heart not from the nerues; for then when these are cut away, the pulse should cease; and the heart taken out of the chest could not be moued, which we find otherwise by dissection of liuing creatures.

CHAP. XII.

Of the substance, ventricles and eares of the Heart.

He substance of the Heart is a thicke [tab. 10. fig. 3. sheweth this] and red flesh, being made of the thicker part of the blood; it is lesse red then the flesh of Muscles but harder, more solide and dense, that the spirits and inbred heate which are contrayned in the heart and from thence powred into all parts of the body should not exhale; and that it might not be broken or rent in his strong motions and continuall dilatation and constriction. And it is more compact, spisse & solid in the cone then in the *basis*, because there the right fibres meeting together are more compact, right as it is obserued in the heads or tendons of the muscles. This flesh is the seat of the vital Faculty and the primary and chiefe cause of the functions of the heart, which consist especially in the making of vitall blood and spirits. For it hath al manner of fibres right, oblique and transuerse, most strong and most compact and mingled one with another (and therefore not conspicuous as in a muscle) as well for the better performance of his motion, as for a defence against iniuries; wherefore according to the opinion of *Gal* in the 6. chap. of his 3. Book *de motu muscul.* & in the 7. chap. of his 8. Book *de v. s. p. art.* (who sometime calleth it after the common name of the bowels a

Where is the
seat of the vi-
tal faculty.

The heart hath
al kind of fi-
bres.

PAYEN-

Parenchyma; sometime the fleshy bowell) it is not a muscle, because it hath all kinde of fibres and is not moued with a voluntary motion, for after *Galen's* determination a muscle is the instrument of voluntary motion: but the motion of the heart which dependeth vpon his substance and flesh is not Voluntary but Naturall, neither can cease so long as the Creature liueth; but the action of the muscles resteth sometimes and is againe set on worke according to the determinate purpose of the Creature to which it is obedient. Notwithstanding *Hippocrates* in his Booke *de Corde* calleth it a very strong muscle and not vnworthily; for he defineth a muscle to bee flesh rowled into a globe, and such is the flesh of the heart: wherefore both of them resting vpon their owne definitions haue deliuered the trueth. And therefore *Picholomeny* answered for *Hippocrates* that there is in vs one motion Natural whose muscle is the heart; another motion voluntary to which all the other muscles of the bodye are obedient; and he maketh a generall definition of a muscle, that it is a fleshy instrument working motion in a creature: vnder which the heart also may be contayned.

The perpetuall motion of the heart because of the continuall generation of spirits (because euery part standeth in neede of them) is double consisting of a *Diastole* or dilatation, and a *Systole* or contraction, which is accomplished by the fibres: for as long as the Creature liueth it is dilated and contracted, and betwixt either of these motions commeth a rest or cessation: for contrary motions, saith the Philosopher, cannot be without a rest between them.

It is dilated when the cone or end is drawne to the *basis* with right fibres, and then it becommeth short indeed, but his sides are so distended that it appeareth sphericall or round. The vse of this motion is to drawe blood into the right ventricle by the hollow veine, and ayre into the left by the venall artery, the valves falling downe and giuing way to their entrance; but it is contracted when the cone or poynt departeth from the *basis*, and then the heart becommeth longer indeed but narrower, the right fibres being loosed to their length, and the transuerse which encompasse the heart round being strongly gathered together and straightned, the valves of the hollow veine and the venall arterie partly shutte, but those of the great artery and the arteriall veine are opened, yeelding out-gate to the blood out of the right ventricle by the arteriall veine into the Lungs, and to the vitall spirit out of the lefte ventricle into the great artery, and to a portion of the vitall blood together with the soote through the venall artery. This motion of the heart is called *Systole* or contraction and depression.

This contraction is not a little helped, if not altogether performed, by certayne strong ligaments [*Tab. 10. fig. 6. L, fig. 9. H H*] which are stretched in the inmost parts of the ventricles of the heart; for when these being contracted doe fall, they also drawe ogethether with them the coats of the heart inward.

Finally the oblique fibres which ly obliquely along the length of the heart, are the cause of the small rest that is betwene these contrary motions; and those things whether blood or spirits, which are drawne into the heart by their helpe are a little while reteyned in the ventricles, the heart being on euery side straightned about those things it conteyneth: but if in the dissection of a liuing Creature you carefully obserue the motion of the heart, you shall discerne foure motions distinguished by their seuerall times and places, whereof two are proper to the eares of the heart, and two to the ventricles. The cauities of the heart which we call ventricles, *Hippocrates* called *γαστρίαι*, i. Bellies, so doth *Galen* in the 11. Chapter of his 6. Booke *de vsu partium*, but by a diuerse name *κοιλία*. They are two very notable differing in largenes and in forme.

The right [*Tab. 10. Figure 3. G G*] is not exactly round, and hath a proper superficiall circumscription of his owne, semicircular and crescent like a halfe Moone, for the belly of the partition which is like a semiorbe stands out into it. This, sayeth *Hippocrates*, compasseth *Caudam cordis*, that is, the taile, he meaneth the poynt or cone of the heart, but reacheth not to the very extremity, yet lower sayeth *Vesalius* then the left ventricle doth. It is broader also and larger much then the other, because it is to containe a farre greater quantity of blood, therefore *Galen* in the 7. and 12. Chapters of his sixt Booke *de vsu partium* and an ancient Greeke Physitian of *Ephesus* called *Ruffus*, call it the bloody ventricle and *venosus*, that is, the veiny ventricle. His flesh is more laxe and soft and his partition thinner [*Tab. 10. figure 5. 2 R*] in compensation of the waight of that it contayneth, that the heart might not be over-ballanced. Into this the ascending hollow veine whilest the heart is dilated powreth blood, that in the dennes which are among the fibres of it, it might by the heate of the

How *Hippoc.* is to be understood when he calleth the heart a muscle.

The double motion of the heart. Contrary motions must haue a rest betwene them.

I, The Arteriall veine.
K, His branch going to the left Lung.
L, His branch going to the right Lung.
M, The top of the right eare of the heart.
NN, The hollow veine.
O, The trunk of the great artery.
P, His descending trunk.
Q, The left Axillary artery.
RS, His ascending trunk.
T, The right axillary artery.
UV, The Carotides or sleepey arteries called also *Soporiae*.
W, The trunk of the Veason or rough artery.
X, The right nerue of the sixth paire.
Y, Certaine branches making the right Recurrent sinew f.
Z, The left Nerue of the sixth paire.
a, Certaine branches making the Recurrent Nerue.
b, A sinew of the same offered to the left Lung.
c, The left Recurrent Nerue.
d, A small Nerue attaining to the Basis of the Heart.
e, The Lobes of the Lungs.
f, The Midriffe or Diaphragma.

III. Figure.

- ACD, Portions of the vessels of the heart.
B, The right eare of the heart.
E, The left eare of the heart with a part of the Venall artery.
F, The point of the heart called the Cone and *Mucro*.
GG, The right ventricle of the heart.
HH, The left ventricle of the heart.
II, The partition called *Septum* which distinguisheth the Ventricles.

IV. Figure. and V.

- AB, A part of the Hollow-veine from the Midriffe to the Jugulum. CCC, The orifice of the hollow-veine opening into the right Ventricle. DE, The orifices of the descending and ascending hollow veine. F, The rugous or vnequal inside of the right eare of the heart, which is placed in the left side, because the heart is dissected through the midriff. G, The beginning of the Crown-veine of the heart. HHH, A circle bunching out in the orifice of the hollow veine. KLM, The 3. Values of the hollow veine. NN, The Filaments or Fibres of the Values. OO, Certaine fleshy excrescencies to which these Filaments do grow. P, A cavity regarding the orifice of the arteriall veine. QR, A part of the heart compassing the right ventricle. V L, Figure. AB, A portion of the hollow veine and the great Artery. CD, The orifice of the arteriall veine, the mouths also of his two branches. EFG, The three Values or Flood-gates, to which those Filaments are impanted. M, the right eare of the heart inuerted and hanging downe. Fig. 7. A the trunk of the great Artery. D, A portion of the arteriall veine. CC, The orifice of the venall artery. DD, A bunching circle in the same orifice. EF, The two Values of the venall artery. GG, Filaments drawn downward from the Values HHH. The fleshy portions to which they are fastned. I, The left eare of the heart turned inward. K, The wall of partition betwixt the ventricles. L, A boosome or cavity reaching the orifice of the great Artery. MM, A portion of the heart compassing the left ventricle. Fig. 8. A the orifice of the great Artery. BCD, The Values that are set before that Orifice. EF, the beginning of the Coronall Arteries. G, Portions of the same arteries strutting forth. H, the Orifice of the Venall artery IK, his two Values. L, the filaments of the same. M, the fleshy portions to which they grow. N, the left eare of the heart inuerted. O, A portion of the arteriall Veine. PQ, the substance of the heart compassing the left Ventricle. R, the wall betwixt the ventricles of the heart called *Septum*. SS, A certaine substance at the roote of the great artery which sometimes in Beasts is bony.

heart be reboyled, attenuated and purified, both for the generation of vitall spirits, as also for the nourishment of the Lungs: for the greater part of that blood in the *Systole* or constriction of the heart is powred out into the Lungs by the Arteriall veine, but the thinner part swea-
teth through the partition into the left ventricle; for this right vètricle was created especially for the Lungs sake, as being found onely in those creatures which haue Lungs; but in those
Creatures which doe not respire but onely transpire as Fishes, this right ventricle is not
found. And so the heart maketh recompence vnto the Lungs sayeth *Galen* in the 10. Chap.
of his 6. Booke *de usu partium*, which drew in ayre for his behoofe, by making and sending
them nourishment fit for them.

Respiration &
transpiration.

The left ventricle [*tab. 10. fig. 3. HH*] is made iust in the middest of the heart; if you take
away that part which made the right you shall better perceiue it. It is narrower then the
former, because it is made to contayne a lesse quantity of matter, and his cavity is rounder,
and goeth sayth *Galen* in the first chapter of his 7. book *de Anatom. Administ.* (though *Vesalius*
be of another minde as we haue sayed) vnto the verie end of the cone. His flesh or wall is
thrice so thick [*tab. 10. fig. 8. QR*] as that of the other as well because of the smalnesse of his
cavity which must needs leaue the sides thicker, as also for that it preserueth the in-bred
heat: it is also harder and more solide to keepe in the vitall spirits that they do not exhale or
vapour out, & to poysse the body; the thicknes of this and subtilty of the contents answering
to the largenes of the other, and thicknes of his contents, that so the hart might not incline
too much on either side. In this the vitall spirits are laboured and containd together with
the arteriall blood, wherefore *Galen* in the 7. and 11. chapters of his sixt book *de usu partium*,
and *Ruffus* call it the spirituall, others the spongie, ayry and arteriall ventricle.

The left ven-
tricle.

The reason
of his thick-
nesse.

The poysse of
the heart.

For in the cavity of this ventricle the vitall spirits are laboured, and from hence by the
arteries are distributed through the whole body to cherish the in-bred heat of the parts, to
reuiue it when it growes dull or drowsie, and to restore it when it is consumed.

What is con-
tained in it.

The matter of this spirit sayth *Galen* is double, ayry and bloody mingled together. The
ayre drawn in by the mouth and the nose and prepared in the Lungs, is carried through the
venall artery into the left ventricle whilest the heart is dilated. And the blood attenuated &
concocted in the right ventricle, is partly distributed into the Lungs by the arteriall veine
for their nourishment, partly is drawne by the left ventricle through his wall and retayned
by an in-bred propriety which being mingled with the ayre is absolved and perfected by the
proper vertue of the heart, his in-bred spirit, heate and perpetuall motion, and so putteth
on the forme of a spirit, which is continually nourished by the arteriall blood. This blood
thus fraught with spirits in the contraction of the heart is powred out into the great artery
to sustayne the life of the whole body; for all life is from the heart and the vitall spirit.

The matter
of the vitall
spirit.

The inward face of both the ventricles is vnequall and rugged, that the substances which
come into the heart should not slippe out before they are perfected, for which purpose also
the valves doe stand in great stead.

The inward
superficies of
the ventricles.

That inequality commeth partly by reason of many small dennes which are more nota-
ble in the left ventricle, (wherefore *Hippocrates* in his booke *de Corde*, sayth it is more broken
and abrupt then the right, because here Nature hid the diuine fire which the Poets feyne
Prometheus stole from heauen to giue life vnto man: and *Hippoc.* because of the great heat of
this place thought it to be the seate of the soule) partly because there are certaine smal fleshy
particles [*tab. 10. fig. 5. O O fig. 6. L fig. HH fig. 8. M tab. 12. fig. 2. ss*] which about the cone of
the heart appeare small and slender, to which the neruous fibres of the valves [*tab. 10. fig. 7.
GG fig. 8. L*] called by *Galen* in the 8. Chapter of his 6. Booke *de usu partium*, and by *Ar-
changelus* the ligaments of the heart, do grow.

Whence the
inequality is?

Prometheus
fire.

These ventricles are diuided by a wall or partition [*tab. 10. Fig. 3. H, Fig. 6. HH Fig. 7. K fig.
8. R*] least the contents should bee mingled and shuffed together, which on the right side
beareth out as we sayed and is gibbous; on the left concaue and hollow, and is of the same
thicknesse with the left side of the left ventricle, as if the heart were onely made for the left
ventricles sake.

The wall of
the ventricles.

This wall is also full of holes and small trenches (it may be *Aristotle* therefore called it a
third ventricle) that in them the blood might be wrought into a further thinnesse; porous
also it is especially on the right side, that the blood might more freely passe out of the right
into the left side for the generation of vitall spirits, which *Galen* insinuateth in these words,
in the 15. Chapter of his third booke *de Naturalibus facultatibus*. Out of the right cavity that
which is thinnest is drawne by the pores of the wall, whose vtmost ends a man can scarce discern,
because

because in dead bodies all such passages fall together. That the blood is carried by these passages it appeareth because nature neuer endeououred any thing rashly or in vaine; but there are many trenches as it were and deep caues in the partition which haue narrow determinations. Thus far *Galen*.

How best discerned.
The opinion of some learned men.

These breathing passages are most conspicuous in an Oxe heart after it is long sodden. But there are some as *Varolius*, *Columbus* and *Vlmus*, who deny that there is any such passage, and will that the blood should be carried by the arteriall veine out of the right ventricle into the Lungs, part of which to remayne for their nourishment, and the remaynder to be conuayed after some alteration in the Lungs mingled with the ayre which is drawne by the breath through the venall artery into the left ventricle of the heart for the nourishment and generation of the vitall blood and spirits.

But wee will leaue this subtle question to Philosophers, for vs it shall bee sufficient to haue made this mention of both waies by which it may passe, leauing the Controuersie to farther disquisition.

The deafe-
eares:

At the Basis of the heart on either side hangeth an appendix [Table 9, Fig. 2, I K, Table 10, Fig. 3. B E] which is called the Eare, not from any profite, action or vse it hath, sayeth *Galen* in the fifteenth Chapter of his sixt Booke *de vsu partium*, and therefore wee in English call it commonly the deafe-eare, but for the similitude; for it hath a long Basis and endeth in an obtuse or blunt cone or poynt.

Their situa-
tion.
The right.

These are placed about the ventricles before the orifices or entrances of the vessels which carry matter into the heart. The right [tab. 9. Fig. 2. I, tab. 10. Fig. 1, B. fig. 3. B] which is placed neare [table 10, fig. 3. A] the hollow veine is the larger, and maketh as it were a common body together with the veine, and his cone or poynt looketh vpward. But the left [tab. 10. Fig. 2, F. fig. 3, E] placed at the arteriall veine [Table 10. fig. 3, D] is much lesse, because the orifice of this vessell is much lesse then that of the hollow veine, and beside ayre followeth more freely at a narrow passage then blood. It is also sharper and runs more on the side of the heart and is more rugged and vneuen on the outside then the right, harder also and more fleshy and thicker, for the eares haue a correspondency with the ventricles, as seeming to bee by Nature framed to bee assistant in some preparation of the matters which belong to the heart. They are hollow as making way vnto the heart.

Why the eares
haue corre-
spondency
with the ven-
tricles.

Their Figure:

Their substance is peculiar and such as is found in no other part; much like the scarfe-skinne, and membranous that they might endure the force of attraction without breaking, and also that they might better follow the motion of the heart; for they are like values stretched and contracted; when they are full and extended then are they gibbous and smooth, but when they are contracted then they appeare outwardly rugous and wrinkled, and within they resemble the vnequall superficies [tab. 10. fig. 5. the right inuerted I rugous fig. 7, the left inuerted 1. fig. 8, N] of the ventricles.

Substance.

They are thin that they might more easily be contracted, soft and neruous for strength for that is strongest which is most sinewy.

Their vse,

The vse of these eares is that whereas the blood and ayre rush violently toward the heart these should take them vp by the way, and keepe them as in a safe and let them into the heart by degrees, otherwise the creature should bee in danger of suffocation, and the heart of violence in their sudden affluence. Moreover they defend the vessels to which they are set in the motions of the heart which haue a soft and thinne coate, and therefore otherwise (when they are stretched in sudden repletion) might be subject to cracke or burst. *Hippocrates* sayed they serued the heart as fannes to coole it, or as bellows to smithes forges to gather in the spirits as they gather in wind.

CHAP. XIII.

Of the vessels of the Heart and their values.

4. vessels.

Their positi-
on.

Here are seene about the Basis of the heart in the outward sides of the ventricles foure vessels and so many orifices, whose originall some would deriue from the heart, as *Vesalius* and *Varolius*, and they are in each ventricle two. *Hippocrates* in his Booke *de Corde* calleth them the fountaines of humane Nature. In the right the hollow veine [Table 9. Fig. 2, F tab. 10. Fig. 1, C, Fig. 2. NN] and the arteriall veine. [tab. 9. fig. 2. G] In the left the venall artery [Tab. 10. fig. 2. G H] and the great artery. [Table 9.

Fig.

veine:

veine : how then is it possible that blood should bee laboured in the heart for the nourishment of the whole body when as no blood can passe out of this Ventricle into the hollow veine but onely into the Lungs? Wherefore it was necessary that Nature should provide a way out of the Lungs into the hollow vein, from whence branches might be disperfed throughout the whole body.

The arteriall
veine.
A veine by of-
fice.
An artery by
substance.
His originall.

Archangelus
his argument.

The other Vessell of the right Ventricle is the Arteriall Veine [table 9, Figure 2 G. tab. 10. figure 6. C D. table 11, Fig. 1 C] or the arteriall vessell. A veine it is, because of the office it hath to transport blood, an artery because his frame and substance is like that of an artery. It is fastned to the ventricle with a lesse orifice [tab. 10, fig. 7, C D] then the hollow veine, [table 10, figure 5, C C C] and from thence some say it hath his originall, yet it may better be imagined to be a branch and off-spring of the great arterie, because (saith Archangelus) it is most likely that a veine should come from a veine, and an artery from an artery; therefore the Venall artery, which though it have the vse of an Arterie, yet having the single coate but of a veine hath his Originall from the Hollow-veine made also of one single coate. And so the arteriall veine having the vse of a veine but the double coate of an arterie, most likely proceedeth from the great arterie which hath a double coate. Of which opinion also are Varolius and Laurentius, and it is further confirmed by their Connexion which in the Infant vnborne is more conspicuous.

The true ori-
ginall of the
arteriall veine.

The vse of the
single coate of
this arteries.

But theverie truth as I conceive is, that it ariseth as other spermatieall parts do from the seed. His coate is not simple as that of a veine, but double [tab. 11. fig. 3, B C] as an artery, and that for the vse as well of the Infant in the wombe as of the man afterward; of the Infant, that the Mothers arteriall blood and vitall spirit which it carrieth into the Lungs, dooing therein the office of an arterie, should not breathe out as it would if it were as thin as a veine: of the man afterward (and in him it dooth onely the dutie of a veine, not of an arterie) partly because in respirations it was not fit it should be easily dilated and contracted, as it would have beene if it had had the single coate of a veine; for then there would not have beene capacitie sufficient in the Chest for the instruments of breathing, and beside the blood should have had too free and full accessse to the heart; partly, because the Lungs which are of a spongy and light substance required to be nourished with a thinne and vaporous not with a thicke and crasse blood (for every thing is nourished with aliment likest vnto it selfe) which could not have beene either so prepared or contained in a vessell with a single coate, as in one with a double.

His good
vse of this sin-
gle coate.

We will add also that cause whereof Hippocrates maketh mention, that is, that the right ventricle which is not so hot as the left, might not be as much cooled as the lefte, and so at length his heate extinguished. For seeing that the branches of the Veazon which draw in the cold aer are divided between the branches of the arteriall veine and venall artery, [tab. 11. fig. 1, B C D] if the coate of the arteriall veine were but one, it would receyue as much aer as the venall artery whose coate likewise is but one, and so both ventricles should be alike refrigerated; whence it must needs follow, that the left having more heate then the right, the heat of the right must of necessity be in time extinguished, the heat of the left remaining inviolate; wherefore Nature made this vessell thicker and so narrower, to carry aer not so much for refrigeration as for refection.

His amplitude
His diuision.

This is a very notable vessell, that so much as it becommeth lesse by the thickenesse of his coates, might be recompenced in the largenessse of the Vessell, and so the Lungs have sufficient nourishment.

It leaneth vpon the great Arterie, and turning his bulke vnto the left side, is diuided into two [table 10. figure 6, C D. tab. 11. fig. 3, F F] trunks which are carried to the lefte and the right Lungs, and there distributed quite through into innumerable [table 11. Fig. 3, G G] branches.

His vse.

The vse of this vessell is in the contraction of the heart, to receyue the greater part of the blood out of the right Ventricle (in which it is made thinner and lighter that it might passe out more forcibly) and to carry it into the Lungs for their nourishment. For the heart seemeth to make retribution to the Lungs, yeelding them blood for their nourishment, because they sent aer vnto him for his refection.

But although this Veine was made thicke and hard, that it might not too easilie be either contracted or dilated, yet it is not so hard, but that his branches are contracted and dilated by the chest; and so in the next dilatation of the heart the blood must needs returne into the heart by the same way it came out; but against this inconuenience provision is made

made by three Valves [table 10 figure 6, *KEG*] which are set to the Orifice of this trunk where it swelleth a little.

These Valves haue their Originall from the very coate of the Veine, and being placed inward do looke outwarde, and each of them is like a semi-circle or halfe-moone, or the Latine Letter *C*. If all these three be together stretched and set vpright, they seeme to bee but one great Valve stopping vp the whole Orifice, and whilst they are stretched carry their Figure of the halfe-Moone; but when they sinke or flagge then they become rugous and resemble the Moone in the first quarter.

Whence the valves are. Their Figure.

Their outward Couering or Circumference, as also is that of the great Arterie, is more solide then the rest of their body; for where in both Orificies they touch themselves or ioyn some way together, they become so indurated, that they appeare to bee like a long and rounde Cartilage.

The vtter coate of this vessell.

The Venall artery [Tab. 10, fig. 2, *GH* not rightly expressed tab. 11, fig. 1, *D*] is a vessell of the left Ventricle. An artery because of his vse, for it containeth and bringeth aer, as also because it beareth as other Pulses doe; not so indeede that it can be discerned by the eye; but so it must of necessity be, because it is continued with the left ventricle where is the originall of pulsation. A veine it is as being of the substance that veines are of.

The venall arteries. It hath pulsation though not visible.

It proceedeth out of the left ventricle of the heart at his Basis with a spacious and round and open orifice [table 10, fig. 7, *CC*] greater then that of the great artery. It is supposed to haue his beginning out of the softer part of the ventricle; but it may better be beleued to haue sprung out of the hollow veine if wee marke the connexion that is found in Infants vnborne.

It hath but one thinne and simple coate in growne bodies, that the Lungs might bee his coate but nourished single.

Why this vessell
is to be capaci-
ous, many rea-
sons.

nourished with defæcated thinne and vaporous blood brought by it but sent by the heart, and that in a greater quantity then a thick stiffe vessell would carry : because the Lungs are parts of great expence as well because of their continuall motion, as also for the rarenesse and loosenesse of their substance which suffereth the thinner part of the blood to exhale from them : againe it was needfull that this vessell should be capacious, because the heat of the left ventricle required great store of ayre for the tempering of it, beside that it needed for the reparation of spirits : for in growne men it hath the vse of an artery to carry ayre, and not of a veine as it had whilest the Infant was in the mothers wombe : and againe, the larger it is and more spacious, the better may the smoake and soote passe through it into the branches of the weazon without infecting the ayre it bringeth into the heart, which in a narrower passage would necessarily haue beene mingled : and in the Infant it had no vse of a double coate because it onely carried the Aliment of the Lungs vnto them from the hollow veine.

The right
branch.
The left.

It is a notable vessell, and as soone as it is gotten out of the heart is diuided into two trunks [*tab. 11, Fig. 4. B B C D*] so that it seemeth to be a double orifice of the same vessell. The right of these is sent vnder the *Basis* of the heart into the right Lung, [*tab. 11, Fig. 1. D*] The left into the left like the arteriall veine, and so they are both disseminated through the Lungs, and make the representation of rootes [*tab. 11, Fig. 4. E E E E*] and may be compared to the rootes of the gate-veine : for as it doth sucke the nourishment with his ends or extremities, so the venall artery is deriued into the Lungs to draw ayre out of the branches of the weazon. But at the originall of this vessell and the great artery, they both meete and are ioyned together, by the interposition of a good thicke and large particle which in the Infant was perforated and made a passage as wee shall declare hereafter. The vse of this venall artery is in the dilatation of the heart to draw ayre out of the Lungs for the generation of spirits, and in his contraction to expell or drive out into the Lungs a portion of the vitall blood for their nourishment and life, as also the soote and smoake that ariseth from the flame of the heart : but least all the ayre should returne againe out of the heart into the Lungs, there groweth to the orifice of this vessell a membranous circle [*tab. 10, Fig. 7. DD*] out of the substance of the heart, which is ledde inward and deuided into two valves [*table 10. fig. 7. F F, tab. 12, Fig. 2. r*] bending from without inward; which as they excede in largenes the values of the hollow veine, so also they are stronger, hauing longer thredy strings [*tab. 10. fig. 7. G G*] to which more fleshy [*tab. 10. fig. 7. H H, tab. 12. fig. 2. ss*] explanations or risings do accrew; one of these valves looketh to the right side another to the left, which when they are ioyned do resemble a Bishops myter.

The vse of the
venall artery.

His valves.

Why but two

They are but two because this vessell was not to be ouer closely shut and that for two causes : first, seeing that all parts need vitall spirits and blood to be sent vnto them for their life, the Lungs also must neede them; wherefore as they receiued Alimentary and nourishing blood by the arteriall veine, so were they to receiue vitall by the venall artery; therefore in the venall artery there is alwayes containd subtile and arteriall blood, which that it may be, it hath onely two valves set to it, that in the contraction of the heart the way might not be altogether stopped vp, but so much space lefte as was necessary for the transuersion of vitall blood.

The necessity
of them.

But if the values were wanting then would the arteriall blood in contraction flow forth in greater quantity and with more violence, and so the great artery and consequently the whole body should be defrauded. Again, that if there should bee any smouldry excrements ingendred betweene the ayre attracted and the natue heate which is coneyned in this ventricle, they might haue free egress this way into the Lungs and so goe out by the weazon; which otherwise if they were retayned might endanger the suffocation and extinction of the creatures naturall heate.

The second vessell of the left ventricle is the great artery, of which though wee doe entreat at large in his proper place, yet it will be necessary to discourse of it here so far as shal make for our present purpose.

CHAP.

CHAP. XIII.

Of the great Artery and his values and use about the Heart.

His great Artery called *Aorta* was made before the heart; having as the heart a beginning of generation from the seed, out of which it is immediately made at the same time that the other parts are. Albeit his originall of dispensation and radicalion be from the left ventricle of the heart, from whence it issueth with an open mouth and patent orifice to receive from the same when it is contracted blood and vitall spirit laboured in it to be distributed together with the heat into the whole body. Which blood and spirits that they should not returne into the heart againe when it is dilated, there are set in his orifice [*tab. 10. fig. 8. A*] three [*table 10. fig. 8. E C D. tab. 13. character 1, 2, 3*] values like halfe Moones bending from within outward as it is in the arteriall veine, but greater and stronger because the body of the great artery is harder then that of the arteriall veine: these values are also a hinderance that the nourishment or Chylus drawn by the mesaraicke arteries out of the guttes should not be presently conveyed into the heart.

The great artery.

His valves.

The cartilage.

Or bone.

There is also placed at his orifice to establish him the better, a hard substance sometimes gristly, [*table 10. Figure 8. S S*] which in some Creatures as red Deere is a very gristle, sometimes in greater creatures it is a bony gristle for it seldome growes into a very bone, as *Galen* sayeth in the 10. Chapter of his 7. Book *de Administ. Anatom.* it doth in an Elephant: but in a man it is not so to be found. And these are the particles of the heart in a perfect Creature after it is brought into the world: now it followeth that we speake of the vessels in the heart of an Infant before the birth.

CHAP. XV.

Of the union of the vessels of the heart in the Infant vnborne which is abolished after they come into the world.

He structure and connexion of the vessels of the heart in an Infant vnborne or any other creature yet in the Dammes belly differeth much from that it appeareth to be afterward when the burthen is brought into the world. This *Galen* most perfectly and manifestly explyained in the 10. Chapter of his sixth Booke *de usu partium*. And albeit most Anatomists after him have lightly passed it over, yet will we stand somewhat more vpon it in this place although I spake of it largely in the controuersies of the Booke before going.

Galen the true obseruer of these vnions.

We sayed before that there were foure vessels of the heart, two in the right ventricle, to wit, the hollow veine [*tab. 12. fig. 1, 2, 3. a b*] and the arteriall veine [*Tab. 12. figure 1. m*] and two in the left, the great Artery [*tab. 12. fig. 12. and 3. d f*] and the venall artery: [*Tab 12. fig. 12. and 3. which in the second figure is manifest*] which vessels in the Infant are thus vnited and coupled two and two together. The hollow veine a vessell of the right ventricle, with the venall artery a vessell of the left ventricle: and the great Artery a vessell of the left ventricle with the arteriall veine a vessell of the right ventricle: which vnion of the vessels in men after they are borne is agayne disioyned.

How the vnions are made.

But these vnitions are not alwayes after one manner: for the former (partly because of the neighbourhood of the vessels, partly because of the likenesse of substances they being both veines) is accomplished by the coniunction of their mouths called *Anastomosis*, wee call it inoculation from the similitude it hath with that poynt of husbandry where a science or but a lease is so fitted to another kind as that the sap may runne equally through them both.

The former.

The latter vnion because of the distance of the vessels to be vnited is accomplished by a Canale or Pipe. The first vnion which is by *Anastomosis* or inoculation or apertion and opening of two vessels one into another, is of the hollow veine with the venall artery [*Table 12. figure 1. and 2. a g*] which is to be obserued vnder the right eare of the heart before the hollow veine open it selfe into the right ventricle [*Tab. 12. fig. 2. appeareth at b*] and neare that region where the coronall veine ariseth.

The latter.

For (touching one another so that you may easily thinke them to be but one vessell) Nature bored them with one hole common to them both [*Table 12. a g h*] which is large and patent and of an ouall figure by which the blood passeth out of the hollow veine into the venall artery and so is carried to the Lungs. But least the blood should flowe backe into the

these con-
iunctions.

the hollow vein there is set to the region of this bore or hole which looketh toward the venall artery, a membrane like a covering or lid [Tab. 12, fig. 2, and 3, 1.] thin, hard and transparent, larger then the hole or passage which is fastned onely at the roote; but the rest of the body of it hangeth loose in the cavity of the vessell, that falling loosely and flagging in to it selfe it might the more easily bee turned vp to the vessell of the Lungs, & the venall artery and giue way to the blood flowing forcibly out of the hollow veine, but hindering it from returning thither againe. Wherefore the venall artery in the Infant doeth the office of a veine to the Lungs, but after the birth the office of an artery; for in these whilest the heart is dilated the blood is powred out of the hollow veine into the right ventricle, and from thence when the heart is contracted thrust out by the arteriall veine into the Lungs. But in the Infant the heart being not moued and yet the Lungs requiring nourishment and encrease, Nature deuised the former way by which the blood brought vppe by the hollow veine is not powred into the ventricle of the heart, seeing neither the Lungs stood in need of attenuated blood, neither was there any generation of vitall spirits, but runneth straight into the venall artery and thence into the Lungs.

These are admirable workes of Nature, but the conglutination or ioyning together of the foresayd hole presently after, passeth all admiration; for as soone as euer the creature is borne into the world, breatheth and the heart is moued, it hath no further neede of this hole or passage, wherefore by degrees the membrane is dried vp and the bore closeth and groweth together, so that if you looke for it a few weekes after either in the heart of an Infant or of a Calfe, you would deny that euer it was perforated, but in dryer creatures it sooner groweth vp, in moyster creatures later.

The other vnion is of the great artery with the arteriall veine [Tab. 12, fig. 1, 2, and 3, fg.] by a canale or pipe [Tab. 12, figure 1, l.] for seeing the venall artery performed the office of a veine to the Lungs, it was necessary that the arteriall veine should chaunge his vse into that of an artery: wherefore Nature also made a perforation into the great artery. But because these two vessells were a little distant one from the other [Tab. 12, fig. 1, d m] shee made another third vessell but very small, by which they might be ioyned, so that they are ioyned not by inoculation but by a pipe or canale.

This canall or pipe beginneth [Tab. 12, fig. 1, l.] not from the trunk or stocke of the great artery, but from that region of the trunk carried downward [Tab. 12, Figure 1, 2, and 3, f.] where the left nerue of the sixt payre or coniugation making the Recurrent is circumuolued or rowled about, and the pipe passeth not ouerthwart but obliquely or sidelong from the great artery [Tab. 12, fig. 1, from d to m] to the arteriall veine, where it is deuided into two trunks and appeareth as if the arteriall veine were deuided into three trunks, of which the first passed vnto the left Lung, the second vnto the right; and the third (which is a little lesse then the other two) should obliquely reach vnto the great artery, and is from the Basis of the heart in an Infant in the wombe distant about the breadth of two fingers, in a growne child after birth the breadth of foure: and the longitude of it is so notable that you may put vp your finger betweene the two vessells, but in Oxen you may easily put vp two fingers or more.

This canale or pipe or vessell call it which you please, hath no membrane ioyned to it which might hinder the regresse of the blood out of the great artery into the arteriall veine, because the length and obliquity of the pipe it selfe is sufficient for that purpose. This canale or pipe is not encreased as other parts of the creature are, but as Nature drieth vp the vmbilical or navel-veine and arteries when shee hath no further vse of them and maketh of them small tyes; after the same manner the forenamed coniunctions of the vessells which reach vnto the heart when the creature is brought forth are abolished, and this pipe is by degrees attenuated so that in a short time it is quite dried vp. But in children of three or foure yeares of age it may be found, because of the thicknesse of his roote, but not perforated or hollow.

These vnions or coniunctions are made for the behoofe of the lungs that they might be formed, growe and encrease; and therefore the pure blood of the mother is carried out of the hollow veine directly by the venal artery into the Lungs by inoculation for their generation; for they are formed at the same time with the heart, & being generated and formed they are nourished by the same matter; and encreased as long as the burthen is carried in the womb: but the vital spirit is ministred to the great artery together with the mothers arterial blood from the vmbilicall arteries, and from thence both are carried into the Lungs to pre-

Table 12. in 3. Figures, sheweth the union of the vessels of the heart, as it is found in the Infant, but abolished soone after it is brought into the world.

heart opened. p 1. The fore part of the heart which regardeth the Lungs. q 3. The back-part of the heart, regarding the Spondels or racke-bones. r 2. The values of the venall Arterie, with his Filaments. s 2. The fleshy implantations of the same.

preferue life through the Canale or pipe by the arteriall veine. Wherefore the vse of the coniunction is, that whilst the Naturall and vitall blood is transported vnto the Lungs, it might not fall into the ventricles of the heart; for because the heart is not moued it would remaine there, and so should the Lungs be defrauded; but when the creature is come into the world, it vscth no more of the mothers blood but his owne, where it cannot holde the same course; but it must fall into the heart, and there as afore is shewed must bee changed. But it shall not be amisse to relate the order of Anatomical administration for the finding of these vnions.

The first vnion which is by inoculation, doth elegantly appeare, if the Trunke of the Hollow-veine carried through the Chest from the Midriffe vnto the right eare of the heart bee diuided in the middest, for then wil appeare two holes or passages; the greater which is that of the inoculation into the venall artery, and the lesser which is the hole or passage of the coronary veine of the heart. But the second vnion which is by the Canale or pipe is demonstrated, if the descending trunk of the great Arterie be diuided thorough the middest euen vnto his outgate out of the left ventricle of the heart, for then withinward will appeare the small and narrow passage of the pipe into the arteriall veine.

How to find
out these vn-
ions in dissec-
tion.

CHAP. XVI.

Of the Branches of the great Artery disseminated through the Chest and the Necke.

He great Artery is the largest [table 13. Figure. 1. A] at the left ventricle of the heart whence it ariseth, and before it fall from the *Pericardium* or purse it bringeth forth about his Values or Membranes [table 13, figure 3, character 1, 2, 3.] sometimes one, sometimes two Arteries, which we call *Coronarias*, [table 13, Figure 1, B B] because like a crown the compasse the Basis of the

Table 13. Figure 1, sheweth the trunk of the great Artery, together with his branches as they are disseminated through the three bellies or Regions of the body.

The second Figure sheweth a portion of the Artery as it is on the backe side, from whence it sendeth branches to the distances betwixt the Lower ribbes.

The third Figure, sheweth a portion of the great Artery, where it yssueth out of the Heart is heere shewed open: and by that meanes wee may better perceyue his Coates and Fibres.

Fig. 2, and 3. A A A, A coate like a Spiders web. B B, the inner coate of the artery. C, the vpper coate of the artery. D E, the originall of the Coronary arteries. 1, 2, 3. Three valves set to the orifice of the Arterie in the heart,

heart : afterward yssueth out of the *Pericardium* and is vnequally diuided into two parts, one ascending vpward to the head [Tab. 13. fig. 1, E] which also is the lesse, the other and larger by farre tendeth downward [tab. 13. fig. 1, D] because the parts below the Heart, are many more then those aboue.

Out of the greater descending trunk [tab. 13. fig. 1, D] which in the Chest is large and thicke, these branches following do yssue.

The lower *Intercoastall* Arteries [tab. 13. fig. 1, H H H] which are sent vnto the distances of the eight low ribs.

The Artery called *Phrenica*, that is, of the Midriffe, on each side one [table. 13. fig. 1, K K] which are disseminated through the Midriffe and the *Pericardium*.

The remainder of the trunk pierceth through the Fissure or perforation of the midriffe [tab. 13. fig. 1, *] and cleauing to the bodies of the Spondels or rack-bones, doth diuersely communicate it selfe through the lower belly.

The lesser and ascending [tab. 13. fig. 1, F] trunk being fastned to the Weazon is communicated to all the parts of the body aboue the heart, and first of all it is forked into two notable branches, which vnder the Partell or collar-bones bendeth to the first ribs of his owne side, and therefore it is called *Arteria subclauia*, for the Latines call the collar Bones *Clauicula*, [tab. 13. fig. 1, F G] then the trunk is diuided into the two arteries called *Carotides* or the sleepe Arteries.

The right *Subclauia* [tab. 13. fig. 1, F, his originall is at a] issueth out of the great artery, euen where it is parted into the sleepe arteries, it is higher, larger, and runneth more ouerthwart then the left, whose course to the arme is rather oblique then transuerse.

From these *Subclauia* before they fall out of the Chest (for after they are not of the chest they are no more called *Subclauia* but *Axillares*) [tab. 13. Fig. 1, P P] as soone as they touch the first rib do passe certaine propagations.

From their Lower part, that which is called *Intercoastalis superior*. [tab. 13. fig. 1, I I.]

From their Vpper part yssue, first the *Mammaria* [tab. 13. fig. 1, L L] which vnder the breast bone being reflected together with the Veine, descendeth vnto the Paps and the Muscles, [tab. 13. fig. 1, C C C] betwixt the gristles of the true ribs, and so descendeth vnder the right Muscles of the Lower belly vnto the Nauell, where it is diuided into many surcles [table 13. figure 1, d d] and so meeteth with the Epigastricall Arterie ascending vpward. [table 13. fig. 1, e e.]

Secondly the *Cervicalis*, [tab. 13. fig. 1, M M] which yssueth more backward toward the bodies of the rack-bones, and at the 7. spondell of the necke entreth in at the holes of the transuerse proceses of those spondels, and so is communicated to the Muscles, the marrow of the necke, and the Spondels themselves. Betwixt the first spondell and the nowl-bone these Arteries on either side [tab. 13. fig. 1, N N] enter into the scull, and at the Basis of the braine they are vnited.

Thirdly, the *Muscula* [tab. 13. fig. 1, O O] because it watereth the Muscles of the necke.

From the Axillary artery, [tab. 13. fig. 1, P P] so called because it passeth by the Axilla or Arme-hole before it reach vnto the arme, do yssue from the lower part *Thoracica superior* [table 13. fig. 1, Q Q] which deriueth his branches to the Muscles lying vpon the breast. *Thoracica inferior* [tab. 13. Fig. 1, R R] which creepeth downe the whole side of the chest. *Scapularis* [tab. 1. Fig. 13, S] disseminated to the Muscles in the hollow part of the Shoulder-blade. From the vpper part *Humeraria* [tab. 13. Fig. 1, T T] which climbeth to the toppes of the shoulder, and is distributed into the Muscles thereabout. That which remaineth of the Axillary artery [tab. 13. Fig. 1, Q Q] being accompanied with the Axillary veine passeth vnto the arme.

That which remaineth of the ascendent trunk [table 13. Fig. 1, E] lying vpon the sharpe Artery and supported by the Sweete-bread, whilst it is yet in the cavity of the chest is diuided into two vnequall branches which they call *Carotides*, [tab. 13. Fig. 1, X X] or the sleepe Arteries, which rising directly vpward are by the mediation of a Membrane tied to the weazon and the internall iugular veines, and so attaine vnto the head. But of these we shall speake more in the eight Booke.

CHAP. XVII.

Of the Lungs.

THE Lungs which are the instruments both of the voyce and also of respiration, the Grecians call *Pneumones*, because of the reception of the ayre which they call *pneuma*, or from a word which signifieth to breathe, for by breathing inward they drawe ayre, and by breathing outward doe put it forth againe. These Lungs are allowed by Nature to all breathing creatures, and placed in the cavity of the Chest [tab. 3. N O P] because they were to bee a little distant from the mouth least by the affluence of the ayre they should haue beene presently cooled. In living creatures whilest they breath inward they fill the whole cavity of the Chest, excepting the region which wee haue already sayde the membranes of the *Mediastinum* [tab. 3. L] and the heart couered with his purse doe occupy: but when the creature breatheth out then they fall, but not so as they doe in dead bodies flat and flaccid, because they are still full of ayre and bloud: and although they may bee puffed vp in a dead body by putting a payre of bellows into the weazon, yet hardly can you rayse them to such a height as that they will occupy so much place as they doe in a living body. For being to contayne so much ayre as should suffice the diuerse motions of the heart, that we might not be constrained to be alwayes fetching breath to speake, sing, or cry out, it behoueth well that their quantity should be very great.

Why placed in the chest.

How to puffed them vp in dead bodies

Why so great.

Their connexion.

How they follow the motion of the chest.

Galen's opinion for the auoyding of *vacuum* or emptinesse.

His demonstration.

How the Lungs moue when the chest is wounded.

Their figure.

Like a clouen hoofe.

How they are diuided.

And although for the most part they hang loose and at liberty that they might more freely moue, yet by the mediation of the vesselles of the weazon they are suspended and hung to the neck and the backe least they should fall downward, and by the interposition of the *Mediastinum* [tab. 3. G H to A] they are tyed forward to the breast-bone, backward to the rack-bones; also in some places at the sides of the chest they grow to the *Pleura* with fibrous tyes produced from their owne membrane, which is peculiarly obserued in man as in the wisest creature: by which meanes the Lungs which of themselves are deuoyde of all motion more easily follow the motion of the Chest otherwise then for the auoyding of *vacuum* or emptinesse.

Galen verily thought that the Lungs followed the motion of the chest for the auoiding of that *vacuum* or emptinesse which is so irreconcilable an enemy of Nature, because the chest being distended they are dilated as they are filled with ayre drawne in; and the same chest being contracted and the Lungs euacuated by expiration, they fall into themselves: which he sheweth by an instance of a wound of the chest. For if the Chest be wounded so that the ayre can get into it, the Lungs saith he become immouable and doe not follow the dilatation of the chest, because there is ayre which filleth the vacuity or emptinesse of the chest; but when the chest is sound and distended, the Lungs are necessarily dilated least there should bee *vacuum* or emptinesse, and the same Lungs, not for the auoyding of emptinesse, but either being compressed by the chest, or because of the ayre breathed out or both together, they fall necessarily.

But we adde, that Nature taking knowledge of the necessity of the motion of the Lungs, that the chest being perforated the ayre going in by the wound might not hinder the dilatation of the Lungs which is caused for the auoyding of emptinesse, hath knit them in men onely as wee said before to the *pleura*, that so by the necessity of this connexion they should follow the dilatation of the chest though it were perforated. They also adhere to the heart by the arteriall veine [tab. 9. fig. 2. G] and the venall artery.

They haue their figure (which is shewed in the 3. and 4. Tables) according to the proportion of the parts vpon which they rest: wherefore on the outside that they might bee fitted to the cavity of the chest, they are gibbous and swelling; on their inside hollow [table 9. figure 1. and 2. table 14. figure 1.] to giue way to the heart couered with his purse, which with their lobes or diuisions they encompassse round about. When both parts the right and the left are ioyned, they represent the shape of a clouen foote of an Oxe or such like, [table 14. figure 1. and 2.] for as the hooves before are diuided asunder by a line as it were; so the Lungs backward [table 13. fig. 2.] (because of the bodies of the *vertebra* or spondels) haue an oblique impression or diuision, and forward they cleaue in the very middest. They are diuided by the *Mediastinum* [table 3. G G H H] into a right Lung and a left, that one part being hurt the other might serue the vse of the Creature, (for oftentimes as wee see in the

the cutting vp of such as dye of Consumptions of the Lungs, the one Lung on the one side being vlceraed yea and consumed, yet the man may live long with the vse of the other.) And they are onely ioyned together by the mediation of vessels [Table 14. fig. 1] which are disseminated into them from the Weazon and the heart. Againe, each Lung is diuided into two Lobes or Finnes if you draw a line from the place of the fourth rackbone or *vertebra* of the Chest obliquely ouerthwart [Tab. 14. fig. 2] to wit, the vpper Lobe or Finne & the lower, yet so, that in a man they adhere together by Membranous Fibres, so that there is rather a note or footstep of diuision then any true diuision indeede, (though it bee otherwise in Dogges) and the lower is longer then the vpper, and it is so diuided, as well that the whole Lungs might more safely and swiftly bee dilated and contracted (the aer breathed in more easily penetrating into their narrowest passages) as also that they might the more firmly imbrace the heart, and not be compressed when we bow downward. And although they be found to be distinguished (though not with any true diuision) sometimes into three, sometimes into more, sometimes into two, yet rarely shall we find in a man, because of the shortnes of his brest, five Lobes, in a Dogge and an Ape often: and if it happen to be so, then saith *Galen* in the 2. and 10 Chapters of his 7. Booke *de usu part.* They ly very high into the throat vnder the hollow-veine.

The Lobes or
Finnes of the
Lungs

Their substance [Tab. 14. fig. 2] is fleshy (whereupon it is called *Parenchyma* and a fleshy bowell) wouen with three sorts of vessels [Table 14. figure 2, B C D] and couered with a thinne Membrane, which varieth in softnesse and colour, according to the age of the party. In younger men it is faster, in the prime of our age more rare and hollow. For the Lungs being not mooued in the wombe of the Mother as neither the heart, are then thicke and firme as is the substance of the Liuer; red also from the colour of their nourishment, for nourished they are in the Mothers wombe with that wherewith they were generated, that is, blood brought out of the Hollow veine to the venall artery by inoculation, and spirits sent from the great artery to the arteriall veine by the pipe or canale before mentioned: but the infant being borne when the heart beginneth to mooue, his motion and heate softneth and puffeth vp their flesh by little and little, and so being mooued with the motion of the Chest, they also become pliable to the motions thereof, and are lifted vp and fall againe with ease; they lye also bedded as it were betweene the diuisions of the vessels filling vp the empty places, and by that meanes are a defence and strengthening vnto them that they bee not broken in their continuall motions. And this is the reason that *Plato* calleth their motion *αλμα μελινδον*, *saltus mollis* a soft motion, which is furthered in that their substance is full of a slimy and viscid moysture, insomuch that *Varolius* saith that after death if they be cut, yet will they glue together againe by this viscosity.

stance.

Their colour.

They haue a Membrane bred out of the *Pleura*, for where the vessels passe into the Lungs [Tab. 14. fig. 1 C D] there their common coate sprung from the *Pleura* departeth from them, and is finely stretched ouer the superficies or vpper face of the Lungs, to forme and containe their soft substance, which otherwise being shaken with continuall motions would quickly breake off by peece-meale.

Their Mem-
brane.

This Membrane is thinne, that it should not bee burthensome, and soft that it might better stretch with the motion of the Lungs, full also of pores though after death insensible, that if any quitture or matter should be gathered in the chest after a pleurisy or inflammation of the Lungs called *Peripneumonia*, it might by these pores haue yssue, and so be spit out by Cough; albeit wee are not ignorant that in both these diseases the Lungs themselves are affected; which wee are taught by the dissection of Pleuriticall bodies; and also by them which haue recovered of Pleurifies, in whom doth remaine difficulty of breathing, and some payne in the weakned side as long as they liue.

Why the mem-
brane is por-
ous.

This porosity also makes their vpper face smooth, & bedewed with a kind of slimy moysture. Into this Membrane, because it needed but a little sense, there are smal Nerves disseminated from the sixt coniugation, on the right side [Tab. 8. fig. 1 r] after the right Recurrent is framed, but on the left side [Tab. 8. fig. 1 q] before the framing of the recurrent, these Nerves do not reach vnto the substance of the Lungs, least they should be pained or wearied

ried in their continuall motion; and hence also it is, that all the vlcers of the Lungs are without paine.

They haue disseminated through them three vessels [Tab. 14. fig. 1. B C D] whose diuerse branches ride ouer and mingle one with another. These are diuided first into two, as the Lungs themselues are, and presently after into other parts, euery one keeping his course till at length they end in threddy branches at the very superficies of the Lungs, betweene which vessels their substance is circumfused as it is in the Liuer. One of these vessels proper vnto the Lungs is called the rough Arterie, or *Aspera Arteria*, we commonly call it the weazon or winde-pipe. [Tab. 14. fig. 1 B. and Tab. 15.] The branches of this pipe are very great, and disseminated through the middest of the others, and bringeth aer drawne by the mouth and the nose to the Lungs, of which we will speake in the next chapter.

The winde-
pipe or wea-
zon called
Aspera Arteria

The Arteriall
veine.

Two vessels it receyueth from the heart, of which wee haue spoken before, one called the arteriall veine [Tab. 14. fig. 1. c fig. 13. the whole arteriall veine] which out of the right ventricle ministreth to the Lungs Alimentarie blood therein attenuated for their nourishment, and with this blood the naturall spirit and the naturall soule therein residing with all her powers and faculties are communicated to the Lungs.

The other called the venall artery [Tab. 14. fig. 1 D. Figure 4. the venall arterie separated] which is an instrument onely of the spirits, but conteyneth also pure, thinn and vaporious blood; wherefore the aer which was attracted by the winde-pipe, and prepared in the lungs it leadeth to the heart, and from the lefte ventricle bringeth forth vitall blood with the vitall spirit and faculty to the Lungs, partly that therewith they may bee nourished, partly for their life that the in-bred heate may bee cherished, (for life is from the vitall spirite and the

the arteriall blood perfected in the left ventricle of the heart partly that by it the smoake and foot may be carried out of the heart.

These two vessels are farre greater then the magnitude of the Lungs may seeme to require if the proportion be compared to that of other parts, and that because the Lungs with their perpetuall motion do consume and dissipate much moysture; and moreover because they serve not onely to carry out naturall blood and vitall blood with vitall spirits; but also by their extremities doe receive from the ends of the winde-pipe ayre which they leade into the ventricles of the heart; and if any small braunch of these vessels be broken, the Lungs become purulent and yeeld matter vp in coughing, as Hippocrates sayeth in his first Booke de morbis, and in the same place addeth, that the Lungs with their heat do draw vnto themselves phlegme out of the whole body, especially out of the head.

And as the substance of the Lungs is differing from the substance of the whole body, so is their manner of nourishing; for there is no part either so rare, light and spirituous, or which is nourished with so pure, thinne and vaporious blood; wherefore the Lungs haue vessels contrary to those which are in other parts: for in other parts the veins haue a rare and thin coat, that the thicke blood might be freely and speedily distributed to the parts about them; for bodies are nourished with blood drawne through the veric coates of the vessels, but the arteries are thicke and dense or thight that the neighbourparts may for their life draw only subtile and spirituous blood and but a litle of it; because no particle of the body though neuer so small can be preserved without it: but in the Lungs all is farre otherwise. The coates of the veines [Tab 14. figure 3. B C] are thicke and thight, that nothing but that which is very thinne may sweate out, because euery thing is nourished with Aliment of his owne Nature, and the bodie of the Lungs being light and rare doe therefore stand in neede of a pure vaporious and thinne blood.

But because the Lungs as well in respect of their perpetuall motion, as for their store of heate which they haue partly by the vicinity or neighbourhood of the heart, partly by the assiduity of their motion; doe neede more plentifull nourishment then other parts: therefore Nature hath giuen to their arteries the coate of a veine [Table 14. figure 4. F] that they might yeeld vnto the Lungs thinne and spirituous blood plentifully and in abundance: that because the veines in regard of their thickenesse or densitie yeelded them lesse store of nourishment, abundant recompence might be made by the arteries which because of their thinne and rarity cannot containe it from them.

These three vessels some will haue to be moued according to the motion of the Lungs: others according to the heart; onely the weazon or asper arterie is dilated when the lungs are dilated. But the venall artery is moued truely after the motion of the heart, but not with the same motion nor with the same power or vertue that the arteries or pulses are moued with. For the heart in his dilatation drawes ayre from the venal artery; in his contraction he thrusteth forth a part of the vitall blood together with the footy excrements: wherefore this venall artery is emptied in the dilatation of the heart and filled in his contraction.

The vses of the Lungs is, first to bee the instruments of respiration and of the voyce, (for all those creatures that want Lungs vse not to breath and are mute beside) for being dilated, like a paire of bellowes they receive in ayre from the braunches of the windepipes, which they prepare as being the shoppe of the spirits, & by degrees change it for the vse of the heart, which otherwise should receive it impure and rushing suddenly and at once into him; and by this delay and preparation it becommeth a convenient nourishment for the in-bred spirite. For some quality of the ayre is familiar and agreeing with that in-bred spirit, another is full of enmity and will corrupt it; and hence it is that we see those that dwell in houses newly limed get diseases, and especially the fume or smother of coales and such like will presently kill a man.

This ayre the heart in his dilatation draweth vnto it selfe by the braunches of the venall artery out of the rootes of the winde pipe whose mouthes doe meete, whereby hee is cooled; for euery thing that is hot is nourished, cherished and conserued by that which is moderately cold, as Hippocrates saith in his Book de natura pueri: For as a flame being straitened in a narrow place and not ventilated with the ayre is consumed; so our Naturall heate when it wants cooling growes weaker (as they know well which sit in hot houses) and faint and is at length extinguished; for as a flame it is continually mooued; wherefore the Philosophers called the Lungs the Fan or flabell of the heart, & Plato thought that the heart when it was heated with anger was tempered againe by the Lungs.

Why these vessels are so large.

Their difference from other parts in substance & manner of nourishment.

How extraordinary in the Lungs.

How these 3 vessels are moued & by what vertues.

The vses of the Lungs.

New limed houses are dangerous to dwell in.

Againe, when they are constringed and contracted in expiration (for in inspiration and expiration life doth consist saith the Philosopher in the 21. chapter of his Booke *De respiratione*) they drive out the aer that remaineth by the same way, that it may giue place vnto that which is fresh, and make also matter for the voyce: this aer when it comes in is colde, when it goeth out hot, because it hath met with the heate that is conteyned in the Heart. Another vse of them is in expiration to auoide the fuliginous and smoaky sootinesse of the heart and spirits, and the thin and thicke excrements of the Lungs gathered in the branches of the sharpe Artery or Weazon by coughing into the Winde-pipe, which are carried vp as in a Recde and spit out of the mouth, yea sometimes cast out with a cough.

CHAP. XVIII.

Of the Weazon or winde-pipe called the sharpe Artery, or *Aspera Arteria*.

Of the wind-
pipe.

THE third proper vessell of the Lungs the Ancients called simply the Artery, because it containeth aer; the later Writers with *Galen* call it the sharpe artery, because of the inequality of his substance, and to distinguish it from the smooth Arteries; we call it commonly the weazon or winde-pipe.

His position.

It is one and a great pipe [Tab. 15. fig. 1. and 2] giuen to all creatures which haue Lungs; it looketh toward the holes of the nose which open into the mouth, and is placed before the Gullet or *oesophagus* [Tab. 14. fig. 1. A A] vpon which it lyeth in the bottome of the throate, and is carried directly downward from the mouth along the necke (which seemeth to bee framed especially for this cause) into the Lungs, into which it alwayes gapeth very wide and in his lower part is diuided into many smaller Pipes, called by *Hippocrates* in his Booke *de locis in homine*, *syringas* and *Aertras*, which determine in the Lungs with manifold branches. [Tab. 15. fig. 1. b b, c c]

The throtle
or Larynx.

The vpper part of it which is the head, is called *Larynx*, wee call it the throtle: [Tab. 15. fig. 1 and 2. g h] of it we will speake in our History of the mouth: the rest [Tab. 15. fig. 1. a a] is called *Branchius*, because it is moystened with drinke.

His connexion

The head of it or the Throtle is tyed to the throate by his inwarde coate, then by his outward coate it groweth forward, and at the sides of the Muscles and Vessels that neighbour about it, but behinde to the *oesophagus* or Gullet by certaine Fibrous tyes that it may descend downward the safer.

His substance.

The substance of this part is partly Membranous, [Tab. 15. fig. 2 f] partly gristly, [Tab. 15. fig. 2 d d] and is inuested with two coates, one outward arising from the *Pleura* which is thinne and groweth exceeding fast to the Membranous bandes of the Cartilages or Gristles, and is as it were a couering to the pipe, which by this coates interposition is tyed to the parts neere hand, and ioyneth the Recurrent sinnewes neerer to this arterie, and beside leadeth them more safely along.

His outwarde
coate.

The inwarde
coate.

The other coate is inwarde, arising from the coate that inuesteth the Palate of the mouth: this encompasseth the whole pipe, whereby the gristles are most firmely ioyned together; it is thight and solide and much thicker then the outward, by which his thicknesse and solidity the artery is warranted from the iniuries which might come by any sharp Rheume or other matter that should fall from the head or bee hawked vp, as sometimes salt Fleame and putrid, sometimes bilious or cholericke, sometim ill qualited and sharpe quittance which is coughed out of the Lungs, or by any sharpe things that should fall or bee swallowed downe, as fumes or vapors and meats or drinckes of a tart or sharpe quality; yet is this coate in the branches dispersed into the Lungs farre thinner then in the throtle, least it should hinder the attraction of the aer, or the expulsion of the smoake or soote, but in the middle of the pipe it is of a middle consistence.

The sound of
the voyce in
burning Agues.

This coate wouen with right Fibres which runne through his length, is soft and smooth and smeared ouer with a fatty and vnctious humor that the artery might not bee dried cyther when hot aer is drawne in, or when sharpe fumes yssue out in great outcries or clamorous motions, for that such driness would bee very offense to the voyce and the transmission of aer: for when the parts which appertain to the throate and to this weazon are vehemently dried, as it happeneth in burning agues, then follow those sounds of the voyce which *Hippocrates* in many places, calleth *κλαγγή* *Changofas*, which beginne base and end sharp

Table 15. Fig. 1. sheweth the foreside of the Throttle and the weazon, and the branches of the same disseminated through the substance of the Lungs. Fig. 2. sheweth the backside of the Throttle, and of the trunk of the weazon.

sharp, as if the voyce failed in the end as it doth in drunken men; and this kinde of voyce is of euil presage in such Agues; but when the parts are abundantly moistned as in destillations and poases, then the sound is raucous or hoarse, but beside such destillations it is moistned by a humor contained in certaine Glandules [Tab. 15. fig. 1. ii] set at the root of the throttle or Larynx, and others that lye vpon them (for it is rare to finde small Glandules in the pipe it selfe though sometimes it be so) as also by a part of the drinke which insensiblie descendeth by the sides of the pipe [Tab. 15. fig. 1. aa] as we shall say when we come vnto the History of the Larynx.

This coate is also verie sensible, that it might quickly finde fault with that that troubles it and sollicit the Lungs to cough it vp. Betweene these two coates are placed the gristles, and their proper Membranous Ligaments. [Tab. 15. fig. 2. ee] For this winde-pipe is made of many gristles like rings, but not fully round [Tab. 15. fig. 2. dd] wanting a fourth part on the back-side, which are called *Sigmoïdes*, resembling the old Greeke *Sigma*, & our γ thus turned backward, the Physitians in *Galens* time called them *Bronchia*. These all along are equally distant one from another, & the vpper are greater then the lower, and thicker in their breadth, especially in the midst, because their midst standeth formost, that the Arterie might not easily be hurt by outward iniuries.

These by little and little are attenuated and grow thinner, and so go as it were into a membrane, and are knit to the proper membrane of every gristle [Tab. 15. fig. 1. ee] by the interposition as it were of a *Periostrion* Ligament-wise: but this ligament if it may be so called, is in brute beasts more Membranous, and in men more fleshy: or shall we call these ligaments [Tab. 15. fig. 2. ee] small muscles, because they intersect themselves like the intercostall Muscles, and fill vp the distances of the gristles.

And because the gristles do not make a perfect circle or rundle on the backpart, they are so ioynd by the help of membranous productions brought from the ends of the gristles, that the gristles with these membranes [Tab. 15. fig. 2. ff] doe make a perfect and full though not a round circle. And this their substance and structure was more meet for their vse then any other. For if either the weazon had beene made of one gristle, or of many altogether round, it would haue bin alwayes alike open, which would haue bred a difficulty in inspiration and expiration, because it is necessary that it should arise and fall with the lungs. It could not haue bin made onely of a membrane, for then the membrane being soft would fall, and so the cavity not alwaies be kept open; beside that, or any other such soft substance had bin vnmeet for the generation of the voyce, as we may perceiue in instruments when the strings are moist.

The Glandules to the Throttle.

The Gristles of the weazon

Their Forme.

Connexion & Situation.

How they are ioynd behind.

Why this their structure is best.

But

How sound is
made.

But because this pipe was to bee the instrument not onely of respiration, but also of the voyce, it behooved that his substance should be gristly and rigid, or stiffe and harde like a pipe, not onely for the freer egress and regress of the aer, but also for the necessity of the voice, because the sound could not bee made without the collision or beating of the aer as it goeth out against a hard body. For that which soundeth must bee smooth and solid, that there may bee a symmetrie or proportion, and yet a resistance betweene the aer and the substance against which the aer smiteth, at which it may a little rest; wherefore in respect of the sound it might haue consisted onely of one gristly substance, but because the voice could not be formed without inspiration and expiration and these stood in neede of dilatation and constriction, it was necessary it should bee compounded of many gristles and Membranous Ligaments, by which it might performe the foresaid motions. Wherefore when wee draw in our breath, the ligaments which tie the Gristles together are stretched, and do separate the gristles so much asunder as themselves are stretched. Contrarywise when wee breathe out, those ligaments are loosed and doubled and fall into themselves so that the Gristles touch one another, which may bee perceived in a dead bodie if you blowe winde into his weazon: and therefore the Gristles and the instruments of the voice and the membranous ligaments which ioynethem together, are instruments of respiration. For the artery it selfe prepareth the voice for the throttle or *Larynx*, for that is the first and most principall instrument of the voice, as we shall declare afterwards.

The Gristles
serue the
voyce and the
Ligaments
the breathing

The incon-
ueniency of the
rings if they
had bin round

Add to this, that if the gristly rings had been perfectly round, not onely the gullet which is soft would haue beene hurt by their hardnesse, but it would haue beene also a hindrance to the swallowing of the meate, by restraining the iust dilatation of the gullet, especially in the swallowing of solid meates, which they haue prooffe of who rauenously deuoure their meate before it bee chewed: wherefore, that the *Larynx* which is altogether gristlie, should bee no impediment to the Gullet, the Gullet in swallowing is drawne downeward, and the throttle ascendeth vppward.

The diuision
of the winde-
pipe.

When this pipe commeth [Tab. 15, fig. 1, a a] into the capacity or hollownesse of the chest to his fourth rack-bone, it is diuided into two trunks [Tab. 15, fig. 1 and 2 b b] the right going to the right side, the left to the left side of the Lungs, into which when they are passed, they are againe subdivided on eyther side into two other branches to each Lobe, and these into many others, [Tab. 15, fig. 1, c c c c] whose gristles are sometimes triangular, sometimes square, sometimes otherwise formed, and passe on disseminated euen to the extremities of the Lungs, that they may better fit themselves to their dilatation and constrictions, neither be obstructed but bee free for inspiration and expiration, and alwayes open for the auoyding of any matter Rheumaticke, Bloody or Purulent by Cough or otherwise. The branches of these diuisions are placed betweene the branches of the venall arterie and the arteriall veine [Tab. 14, fig. 1, B C D] in the midst, and are greater then either of the other, but so that the Veine is on the backside of it, and the artery on the right, which presently as it comes out of the heart entreth the Lungs, for that it was not safe that his thinne coate should runne along without some Firmament, hauing so active and flippant matter in it. Necessary it was that those branches of the Weazon should bee neere vnto both those vessels and ioyneth mouths with them; and first with the Venall artery, that so there might bee free passage out of the Rough Artery into the smooth for the aer to passe to the left ventricle of the heart, and as free an outlet for the vapours and soote, but not for blood and other humors, vlesse it bee by violent Coughing; wherefore, if at any time they become more open then they should bee, eyther by breaking one of them, or by opening of their orifices, or if any of them should be growne asunder, then part of the blood contained in the branches of the smooth Arteries is powred into these Rough, which hindreth the recourse of the breath taking vp the passages of it, and so suddenly followeth a cough, and the bloode comes vp into the mouth, but if that which insensibly slid downe the Weazon, and so passed vnto his lower pipes do thicken in the outlets which are very small, it breeds such a difficulty of breathing, as that his breath seemeth continually to faile, and hee in great necessity of perpetuall inspiration.

The causes of
coughing of
blood.

The cause of
shortnesse of
breath.

Why they
ioyneth with the
arteriall veine.

Secondly, it was necessary it should ioyneth with the arteriall veine, and that by inoculation, that from the veine it might receiue blood for his nourishment. And this is the manner of the coniunction of the Weazon to the Heart by the mediation of the smooth arteries, and how small propagations of the Veines are inserted into the strings of the winde-pipe for their nourishment, because of themselves they are altogether without blood, but the

the smooth or venous

A part of the fir
high, or the first

the smooth or venall arteries have no Veynes inserted into them, because they themselves containe blood. Moreover, the Rough arteries have small vessels deriued vnto them from the neighbour vessels.

The Vses of this Weazon are, that the Lungs as a paire of bellowes might by it, as by ^{The Vses of the Weazon, First.} a Conduite or pipe draw aer in respiration attracted by the nose and mouth (for the Lungs being dilated, onely the rough artery is dilated) and send it to the heart, and by the same passage constringed, send out from the heart the hot aer which is vnprofitable for it, together with smoaky vapors and sooty excrements, and deliuer them out of the mouth and nose. And againe, that it might bee the instrument of the voice; for to the generation of ^{Second.} the voice which is formed in the Throttle, the aer which is breathed in, and is the proper matter of the voice is required, euen as wee may obserue that in the pipes of the bellowes when they are filled with aer, there is a sound engendred. Wherefore Hippocrates is his ^{Third.} Booke *De Morbis* called it *Organum vocale and spirabile*, a breathing & vocall instrument. And finally, that with violent exsufflation either in coughing, or deepe hawking (for that which is lightly hawked vp comes but from the roots of the tongue) those things which fell from the head, or are gathered in the Lungs might by it bee cast forth.

CHAP. XIX.

Of the Muscles and Nerves which are in the cavity of the Chest.

HAuing runne through all the parts containd in the Chest, and as it were remooued them out of the way, wee meete with certaine Muscles, Nerves and Bones.

Table 16. sheweth the Cavitie of both Bellies without the bowels and the Midriffe, as also what Muscles and what bones remaine when the bowelles and brest-bone are remooued.

TABVLA XVI.

- AB.* The first Muscle moouing the Necke, or the long Muscle.
CC. The second Muscle moouing the necke called *Scalenus*.
DDDD. The outward intercostall muscles.
EEEE. The inward intercostall muscles.
FF. The Muscle called *Serratus maior*, or the second Muscle of the Chest.
G. The Muscle called *Serratus minor*, or the first Muscle of the shoulder-blade freed from his Originall.
H. This Muscle called *Pectoralis* or the first Muscle of the arme separated from his originall.
I. The Muscle *Deltoides* or the second of the arme.
K. The shoulder-bone without flesh.
L. The first Muscle of the Cubite cald *Biceps*.
M. The second Muscle of the Cubite cald *Brachians*.
N. The Clauicle or collar bone bent outward.
O. The first Muscle of the Chest cald *subclauins*.
P. The higher proceffe of the Shoulderblade.
Q. The first muscle of the head or the Lower Oblique.
R. The second Muscle of the head.
S. The fourth Muscle of the Shoulder-blade or the *Leuator*.
TV. The two bellies of the fourth Muscle of the bone *Hyois*.
XXaa. The first Muscle of the backe; whose beginning is at *aa*.
YYbb,cc. The first Muscle of the thigh, called *Psoa*, whose Originall is at *cc*. And his Tendon at *bb*.
ZZ. The 7. Muscle of the Thigh.
d. The holy-bone or *os sacrum*, out of the holes whereof are at *o* certaine Nerves do yssue.

e. A part of the first Muscle of the thigh at the share-bone. *f.* The share-bone bared. *k.* The ninth Muscle of the thigh, or the first Muscle whereby it is turned.

The

- Two Muscles** The Muscles are two, called *Cervicis longi* [Tab. 16. A B] the long muscle of the neck, which being situated vnder the gullet are affixed to the rack-bones. The Muscles which are seated on the sides and behind and doe extend the head and the necke, wee haue in some sort described before in the third Chapter of this Booke.
- Two kinds of nerves.** There are also two kinde of Nerves which passe through the chest; one from the sixth paire of the marrow in the brayne, exhibited in the first figure of the 8. table: another from the spinall marrow which is either in the racke bones of the necke or of the chest; of which also we haue spoken before in the 10. Chapter.

Of the *Claucles*, *Breast bone* and the *Ribs*.

The figure of the collar-bones.

Why not so crooked in women.

Their inequality or roughnes.

Why called *Ingula*.

Their vse.

The breast-bone.

The substance of it.

The diuision of it.

The quantity of the parts.

The gristles of this bone.

The vse of this breast-bone.

The ribs.

THE *Claucles* or *Collar-bones* are called in Greeke *κλάς* because they shut vp the whole Chest; they are two, on each side one, situated ouerthwart in the bottome of the necke and top of the breast. Their figure is not straight but outwardly embowed at the *ingulum* [Tab. 17. fig. 2. H] and on the inside hollow; contrariwise at the shoulder they are hollow on the outside & imbowed within, [Tab. 17. fig. 1, 2, 3.] but in men they are not so crooked as in Apes, and doe neare resemble the letter *J*. Likewise in women they are lesse crooked then they are in men [Tab. 17. fig. 4. R] which maketh them lesse nimble in the moouing of their armes, as wee may see when they offer to cast a stone: notwithstanding they haue a manifest protuberation or swelling, & also two lines [Tab. 17. fig. 1, 2. E, fig. 2, 3. F. G.] that from thence the *subclavian* muscle and a part of the *Pectoral* might arise. They are also on either side exasperated [Tab. 17. fig. 1, K fig. 3, P] toward their ends, from which exasperation or inequality doe proceed certaine ligaments; as also the seventh muscle of the head called *Mastoides*.

These *Claucles* on either side fasten the shoulder-blade to the breast-bone by *Diarthrosis*, a notable gristle being betweene them. [Tab. 17. fig. 5. T S] *Celsus* called them *Ingula à iungendo*, of ioyning or because they are like to the yoke wherein Oxen are ioynd which we call *Ingum*. Their vse is to hinder the shoulder-blade and armes from falling vpon the breast.

The breast-bone is called *sternum*, because it is disposed in the middest betwixt the ribs, [Tab. 17. fig. 9. g h i] or the breast-bone, because it maketh the forepart of the Chest and secureth the parts vnder it. At the end of it is a quistle a little bowed, long and broad like the handle of a Dagger as the ancients vsed [Tab. 17. fig. 6, 7.] and therefore it is dalled *ἐνδοειδής*, the sword-like cartilage or the *Breast blade*.

The substance of it is not solide as other bones, but fungous or Spongy, redde and compounded of bones and gristles. In a childe new borne it is altogether gristly, excepting the vppermost which is a bone from the beginning. Then it is deuided into eight parts; seven of them receiue the gristles of the seven perfect ribbes; the eight receiue the gristle called *ense formis*. After seven yeares they growe better compacted and haue fewer partitions and at length are onely foure. The first [Tab. 17. fig. 6. a] which is the broadest; the second and the last, the rest betweene ioyne into one. The vppermost [Tab. 17. fig. 6. a b c] is larger and thicker then the rest, & representeth the broad knubs or stay at the end of the Dagger handle. The second is like [Tab. 17. fig. 6. p q r] the grasping place, & in the sides of it hath many cauities or bosomes [Tab. 17. fig. 6. k l m n] not equally distant one from another, wherein the gristles of the third, fourth, fifth & sixth ribs are receiued. The third bone is lesse then the first [Tab. 17. fig. 6, 7. s] but broader then the second, & these are all that appeare bony in a growne man.

The gristles of it beside those two which are betweene the collar-bone and it, are, one betwixt the first bone and the second, [Table 17. figure 6. h] another in the end of it long, immouable and triangular [Table 17. figure 6, 7. E] which is commonly sharpned at the end like a poynt of a sword, whence it hath his denomination, for it is peculiarly called the *Breast-blade*. If this gristle bee in children curued downward it offendeth the Liuer and the stomacke, and such children pine away and dye. Here also is that cavity which is commonly called *Scrobiculus cordis*, the Trench or Spooone of the heart. Note also that in women the breast bone is flatter then it is in men because their paps are larger.

The vse of this breast bone is the same with the ribbes. The vse of the breast-blade is partly to defend the parts vnder it, partly to giue scope to the motion of the midriffe.

The ribs which the Greekes call *πλευράς* and *σπάθαι*, are commonly as well in men as in women on either side twelue, [Table 17. figure 9. 10. character from one to 12.] They are many

Table 17. hath two the second the poster the first Figure the The first Figure the right showeth the shape of a Heart. Figure 9. showeth one of the true ribs From the first Ch the scum uppermo

FIG. 1

Table 17, hath twelve Figures, whereof four shew the Coller-bone. The first the anterior part: the second the posterior: the third the lower part: the fourth the Coller-bone of a woman which is straighter then of a man.

The fifth Figure sheweth two gristles placed on either side betwixt the ioynts of the Coller-bone.

The sixth Figure sheweth the fore-side of the breast-bone. The seventh the back part thereof. The eighth sheweth the fore-side of the breast-bone of a woman, together with the hole therein after the fashion of a Heart.

Figure 9 sheweth the fore-side of the bones of the Chest. The tenth the backside. The eleventh one of the true ribs broken. The twelfth sheweth the back-part of the twelfth broken.

From the first Character to the twelfth, in the 9 and 10 Figures are exhibited the twelve ribs: the seven uppermost true ribs: the five lowermost bastard ribs.

TABVLA. XVII.

A 1 2 3. The head of the clavicle which is ioynted to the breast-bone.

B 1. The first angle or corner of this head.

C D 1 2 3. The second and third angles.

E 1 3. The eminent and forward line of the clavicle.

F G 2 3. The lower line which neare G is rugged.

H 1 2 3. The middest of the clavicle or collar-bone which is round.

I 1 2. The exterior part which is broader and crooked.

K 1. A roughnesse in that place.

L M N 3. The lower side of the clavicle which is sinuated and rough, and about N there riseth a ligament which is fixed into the inner proceffe of the shoulder blade.

O 2 3. A swelling of the clavicle opposite to the breast bone.

P 3. The lower roughnesse of the inner side.

Q 1 2 3. The playne or smooth heade wherewith it is ioynted to the shoulder blade.

R 4. The collar-bone of a woman.

S 5. That cartilage or gristle of the collar-bone which is betwixt his ioynt with the shoulder blade.

T 5. The other gristle which is betwixt his ioynt with the breast-bone.

a 6. The swelling or bunching prominence of the first bone of the sternon or breast-bone. b c 6. An impression or doke on eyther hand at the sides of the sayed prominence. d 7. The backside of the breast-bone which is somewhat hollow. e f 6. The bosome or cavity which admitteth the collar-bones. g 6 7. The bosome or cavity to which the first rib is articulated. h 6 7. the articulation or ioyning of the first bone with the second. i 6 7. the sinus or hollownesse to which the second rib is ioynted. k l m n o 6 7. Other sinus or bosomes to which the five hollow ribs are articulated. p q r 6. the lines which remaine after the bones do grow into one. s 6 7. the third bone of the sternon. t 6 7. the gristle of that third bone. u 8. A hole made in the bottom of the breast bone carrying the representation of a heart.

Figure 9. 10. 11 & 12.

A B 9. The ioyning of the ribs with their gristles. C D 9. The articulation of the gristles of the ribs with the breast-bone. E 9. the blunt head of the gristle. F P 9. the gristles of the bastard ribs which are sharpe. g h i 9. the breast-bone in the middest of the ribs. G H 9. the distance betwixt the 11. ribbe where the gristle sometime is parted from the other gristles, but at 12. alwayes. I I 9. An vnequall prominence of the gristles. K 9. the sword-like cartilage. K I I. A bosome running along in the inner side of the rib. L M I I. the head wherewith the rib is articulated or ioynted to the spondel or rack-bone. L. and M sheweth the head whereby it is ioynted to the transverse proceffe. N I 2. the blunt head of the 11. and 12. ribs. O I I. 1 2. A knub into which the 11. muscle of the back is inserted. P I I. An asperity or roughnesse betwixt the two heads which bringeth forth a ligament. Q I I. A roughnesse with a light extuberation into which the muscle of the chest called *Sacrolumbus* is implanted. R I I. The fungous substance of the rib appearing when it is broken.

many

many that having many muscles, the chest might more easily be mooved, yet seldome fewer or more then 12.

Their division

They are divided into true or legitimate, and bastard or spurious ribs: the legitimate are the seven vppermost, [tab. 17. fig. 9. from char. 1 to 8] so called because they perfect their semi-circle. They are ioyned backward with strong Ligaments to the racke bones of the back [tab. 17. fig. 10. S T] by *Diarthrosis*, and that with a double knot to make them the faster.

Their Connexion. And Names.

The vpper knot is to the body of the Spondell, the lower to the laterall processe. Forward they are articulated to the breast-bone [tab. 17. fig. 9. a] by certaine gristles growing vppon their heads. The two vppermost of these are called *Retorta*, the two next *Solida*, the three last *Pectorales*. The bastard ribs are the five lower; softer as being almost gristly, at last they end into a perfect gristle. These five are retorted or bent vppward, and so are glewed together [tab. 17. fig. 9. F F] excepting the last which is the twelfth.

The substance of the Ribbes.

These are also imperfect, because they are knit only to the spondels but touch not the breast bone, that so the Lower belly especially the stomacke and the wombe might better bee dilated or enlarged. The eleuenth and the twelfth are sometimes tyed vnto the Midriffe.

The substance of the ribs is not onely bony (though that bonynesse be but spongy) [tab. 17. fig. 11. R] but euery one hath his proper Cartilage both behinde where they are tyed to the Spondels, and also before where they are ioyned to the breast-bone [table. 17. fig. 9. A B] shewes the coniunction of the ribs with their Cartilages, and C D the coniunction of the cartilages of the breast-bone.]

Their Figure Magnitude.

Their figure is semi-circular or bent like a Bowe, that so the Chest might be the stronger and more capacious. The vpper and neather ribs are the shortest, the middle are the longest and the broadest excepting the first which is the shortest and the broadest of all the rest.

Their cavity.

On the outside especially where they are tyed to the spondils they are sharpe [Table 17. figure 11. P] and vnequall, that from thence the Ligaments might proceede: but on the inside they are smooth least they should hurt the *Pleura*, and yet in the lower part they are hollowed [tab. 17. fig. 11. K] like a gutter quite through their length, into which hollownesse they receiue three Vessels, a Veine, an Artery, and a Nerue.

Their vse.

The vse of the ribs is to bee a strength to the Chest, and a defence to the bowels vnder them, they receiue also the implantations of the Muscles seruing for respiration. Their Gristles also doe make them more plyable in the motions of Inspiration and Expiration euen when we are asleepe.

CHAP. XXI.

Of the bones of the Chest.

THE bones which make the Chest or middle Venter are these. On the forepart the breast-bone, and on the top of it the two coller bones, on the sides foure and twenty ribs; of all which we haue entreated in the chapter going before.

The spondels.

On the backe-part of the chest are the spondels or racke-bones, and the shoulder-blades, of which we will speake in this place, and so put an end to our Discourse of the Middle Venter.

Their number

The Spondels therefore of the Thorax in a man are for the most part twelue [Table 20. Fig. 1, at D] iust so many as there are ribs, for euery racke hath two ribs articulated with it, [tab. 18. fig. 5, D P] wherefore also they haue two cavities, [tab. 18. fig. 1, from C to D] one at their sides, another at their transuerse processe. It is seldome seene that any of the racks are wanting, but much more rare that there should be too many.

The reason of their numbers.

The reason of their multitude is the better flexion or bending of the backe, for they are put together with ioynts knit and tyed with strong Ligaments [Tab. 18. fig. 6. character 5. Tab. 20. fig. 1, R R] betwixt euery one of which there runneth a Cartilage to make the motion nimble and glad. [Tab. 18. fig. 6. char. 1, & 3]

Their Forme or figure.

These spondels haue bodies bunching out in the middest round, embowed aboue [tab. 18. fig. 1 and below [tab. 18. fig. 1, 2, 3, 4, A] plaine, thicker also then the rackes of the necke and lesse solid, thrilled also with small holes made for the passage of those vesselles that deriue nourishment vnto them and the narrow of the backe.

Their processe.

Their processees are some sharpe, cald *Spinales* [tab. 18. fig. 1, & 2, M N P] which bend downward: others transuerse [tab. 18. fig. 1, 2, 3, 4, H I] which are thicker, solid & long ending in a round head for the firme articulation of the ribs: againe, others ascending which are two

[Tab.

ding processees of the some which is in the uerle processe. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

Table 18. sheweth the backward bones of the Chest. Figure 1. exhibiteth the fore-face of the middle Spondell unto which the other ten are very like. Figure 2. the Backe-part of the same Spondell. Figure 3. the backe-part of the eleventh Spondell. Figure 4. the backe-part of the twelfth Spondell. Figure 5. the three middle Spondells of the Chest, together with their articulation with the rib. Figure 6. sheweth the gristly Connexion of two Spondells. Figure 7. sheweth the inward part of the right shoulder-blade. Figure 8. the outward, as the 9. Figure sheweth the side.

TABVLA. XVIII.

- A, 1, 2, 3, 4, The vpper-part of the Spondell, to which the lower part is answerable.
 B, 3, The vpper Appendix of the head of the Vertebra, to which the lower Appendix is like.
 C, 1, The bosome which receiveth the rib marked with B, another lesse bosome at C.
 D, 3, 5, The bosome of the 11. racke-bone to which the 11. rib is articulated, and in the fift Figure it is sheweth together with the rib.
 E, 4, A Sinus or hollownesse in the twelfth Spondell.
 F, 4, A roughnesse or inequality in the bone bringing forth the Ligament or tye of this joint.
 G, 2, 3, 4, The holes that are in the back side of the bodies of the racke-bones.
 H, 1, 2, 3, 4, The transverse processes of the racke-bones of the Chest.
 K, 1, 5, A Sinus in the top of the transverse processes, to which the rib is articulated.
 L, 1, 2, The gibbous or embowed part of the transverse processe.
 M, 1, The hollow part of the transverse processe.
 N, O, P, 1, 2, The spine distinguished in the three sides by three lines.
 Q, 1, A sharpnesse in the inside of the spine.
 R, 3, The spine of the eleventh rack-bone.
 S, 4, The spine of the twelfth rack-bone.
 T, U, 1, The fore-face of the ascending processes.
 X, Y, 2, 3, The back-face of these processes.
 ab, 2, 3, the outward face of the descending processes.
 c, 1, Their fore-face crusted over.
 ef, 4, The ascending processes of the twelfth rack-bone which goe vnder the eleventh.
 gh, 4, The descending processes of the 12. rackbone, which are articulated to the Cavities of the ascending processes of the first rack-bone of the loynes. *ill*, 5, The three middle vertebrae ioyned together. *mn*, 5, The bosome which is in the body of the vertebra, and receiveth the head of the rib. *o*, 5, The articulation of the rib to the transverse processe. *p*, 5, The circular bowing of the ribs from D, to p, backward, from thence to s, forward. *qr*, 5, The ioyning of the rib with his Cartilage. *s*, 5, The blunt head of the Cartilage. *Char. 1, 2, fig. 6*, A Cartilage ioyning the Appendices of either rack-bone to their Bodies. *Char. 3, 4, fig. 6*, The Appendices of either rack-bone. *Char. 5, Fig. 6*, A gristly Ligament ioyning both the rack-bones.

Heere followeth a threefold delineation of the Scapula or Shoulder-blade.

A, B, 7, 8, The bosome or cavity of the blade which is called *Acetabulum*, into which the bone of the shoulder entreteth.
 a, 8, A gristle which enlargeth that cavity, which is also by it selfe described and noted in K. C, D, 7, 8, The neck of the shoulder-blade. E, 7, 8, The lesser processe of the shoulder-blade. F, 7, 8, The knub of the same, vnto which the Clavicle is connected. f, 7, The roughnesse thereof which bringeth forth a Ligament. G, H, 8, 9, The spine of the shoulder-blade.
 I, 8, 9, The thicker part of the spine which hath an Appendix. K, 7, 8, 9, *Acromion* consisting of an Appendix. L, 7, The Sinus of that *Acromion* sustaining the Coller-bone. M, M, M, M, Certaine small dens made by the contraction of the ribs. N, O, P, 7, The inward hollow part of the roote of the spine at N, O. The inward extuberation of the lower side at P. p, 7, The sharpnesse of the shoulder-blade in the vpper side. Q, 7, The Sinus of the lower side from whence ariseth the first muscle extending the Cubite. S, 8, The outward protuberation or swelling of the lower side. T, 8, An impression of the lower side from which ariseth the fourth Muscle of the arme called *Rotundus maior*. U, U, 8, The cavity of the outside of the Scapula. X, 7, 8, 9, An Appendix of the Basis of the shoulder-blade. Y, 7, 8, 9, Another Appendix of the lower angle. Z, 7, 8, 9, The vpper angle of the Basis of the shoulder-blade. q, 7, The inner protuberation or swelling of this angle. a, 7, 9, The bosome of the vpper side of the shoulder-blade. b, 9, The thinnest part of the shoulder-blade. c, 9, Heere sometime is found a small hole through which the veins do creepe for the nourishment of the bone.

M m

[table

[*tab. 18, fig. 1, TV*] and two descending [*tab. 28, fig. 2, and 3, a b*] notwithstanding the transverse proceſſe of the 11. and 12. ſpondels [*tab. 18, fig. 4, e f g h*] doe differ from the proceſſes of the reſt.

Appendices. 5. They haue alſo five *Appendices*, two at their bodies aboue and [*tab. 18, fig. 3, o*] beneath two at the tranſuerſe proceſſes, and one at the end of euery ſpine.

Their perforations. The holes or perforations of the racke-bones are bored according to the thickneſſe of the marrow that muſt iſſue out of them; [*tab. 18, fig. 2, 3, 4, G*] for as the marrow in deſcending is attenuated, ſo are the holes of the lower ſpondels ſtraightned.

CHAP. XXII.

Of the ſhoulder-blades and racks of the neck.

The ſhoulder-blade.
His connection.

 He ſhoulder-blade called *Os ſcapula* is on each ſide one [*tab. 18, fig. 7, 8, 9,*] which hangeth vpon the ribbes on the backſide like a buckler, and is articulated with the ſhoulder or arme and the collar-bone, ioined alſo to the ribs, the bone *Hyois* and the *occipitium* or nowle-bone by the mediation of the muſcles.

His Figure.

The Figure is almoſt triangular, on the inſide it is concauous or hollow [*tab. 18, fig. 7, M*] on the outſide [*tab. 18, fig. 8, VV*] it buncheth, and that bunch is called the *Baſis* of the bone; it hath alſo an angle or corner, & a rib both aboue and below, from which is produced a ſpine tending vpward. [*tab. 18, fig. 9, GH*] The vpper angle is ſhewed in the 18 *table, fig. 7, 8, 9.*

The proceſſes.

The proceſſes of this *ſcapula* aboue are three; the firſt is very ſhort and determineth with a ſhort necke [*tab. 18, fig. 7, 8, CD*] into a hollowed head [*tab. 18, fig. 7, 8, A B*] ſuch as the Anatomists call *acetabulum* wherein it receiueth the head of the ſhoulder-bone. And this hollowed head of the *ſcapula* is compaſſed with a thick griſtle [*tab. 18, fig. 8, a and K*] whereby the cauity is enlarged, leaſt that the head of the ſhoulder ſhould eaſily fall thereout.

Acetabulum.

The ſecond proceſſe is the very end of the ſpine and hangeth over the ioint of the ſhoulder; and therefore it is called *Humeri mucro* or *ſummus humerus*, The top of the ſhoulder, [*tab. 18, fig. 7, 8, 9, K*] and by this proceſſe the ſhoulder-blade is ioined to the collar-bone.

The third is inward and leſſe [*tab. 18, fig. 7, 8, E*] called *Sigmoides*, and this containeth the ſhoulder bone in his ſeate.

The appendices.

The appendices, or if you will, appurtenances of the ſhoulder-blade are five, three are in the inſide and at the *Baſis* [*tab. 18, fig. 7, 8, 9, XR*] affording a beginning to ſome muſcles; and two other out of which iſſue the ligaments which ioine the ſhoulder to that hollow head of the blade we ſpoke of, and alſo the collar-bone to the ſecond proceſſe which we called the top of the ſhoulder.

It hath alſo a double cauity, one aboue, the other beneath the ſpine with the Anatomistes *Interſcapulum*.

The ſubſtance

The bone of the blade is very vnequall, for in the middeſt it is the thinnest, the proceſſes thicke, medullous and ſpongy; it hath alſo certaine perforations by which veines and arteries are admitted for his nourishment.

The ſpondels of the neck.

The Neck which was framed to ſuſtaine the head and to mooue the ſame, conſiſteth of many ſpondels called *vertebrae* or rack-bones, which are commonly 7. [*tab. 19, fig. 2, 3, 4,*] differing one from another and from the reſt of the *vertebrae* of the ſpine.

The firſt rack bone.

The firſt [*tab. 19, fig. 2, 3, FF, tab. 20, fig. 2, 3, 4,*] is called *Atlas*, and hath a thinner yet tighter and faſter body then the reſt, and wanteth the vpper proceſſe or the ſpine. The aſcending and deſcending proceſſes of this rack are hollowed on either ſide, [*tab. 20, fig. 2, 3, EF*] aboue to receiue the two proceſſes of the *occipitium* [*tab. 19, fig. 1, DC*] for the better motion of the head, below to receiue the proceſſes of the ſecond *vertebra*: [*tab. 20, fig. 5, 6, MN*] it hath alſo at the ſides thereof two tranſuerſe proceſſes [*tab. 19, fig. 2, 3, 11, tab. 20, fig. 2, 3, 4, GG*] perforated [*tab. 19, fig. 2, K, tab. 20, fig. 2, H, ſheweth the perforation*] for the aſcent of a veine and an artery into the braine.

The cauity of it.

It hath alſo a cauity or *Sinus* [*table 20, fig. 2, 3, B*] cruſted ouer with a griſtle [*table 20, fig. 2, 3, C*] wherein it receiueth the tooth [*table 20, figure 7, O*] of the following *vertebra*, and at the proceſſes where the racks are ioined there is alſo a *Sinus* on either hand: in the firſt *vertebra* [*table 20, figure 4, Z*] and the ſecond [*table 20, figure 6, y*] it is like a chinck or rift: in the reſt it is orbicular, as alſo it is long in the racks of the cheſt. Through theſe cauities the

Figure 2. sheweth the continuation of the seven vertebra of the necke as it appeareth in the back-part.

Figure 3, sheweth the fore-part.

Figure 4, the laterall face.

Figure 5, sheweth the ligaments which ioyne the first and the second rack-bones.

Figure 6, sheweth the gristles which are sometimes found betwixt these vertebrae.

TABVLA XIX.

A, 1, The hole in the nowle bone made for the outlet of the spinall marrow.

BC, 1, Two heads of the bone *occiput* or nowl-bone, which are articulated to the first rack-bone of the necke.

D, 1, The roughness wherein the ligament is inserted.

E, I, A *Sinus* or hollownes in the back-part of those heads, making a way for the first paire of sinews.

FF, 2, 3, The first rack-bone of the neck.

GH, 2, 3, 4, The cavity of the first rack-bone receiving the two heads of the nowle-bone.

II, 2, 3, The transverse proccesse of the first vertebra.

K₂, The hole of this transverse proceſſe.

L, 2, A cavity which with the cavity of the nose-
bone marked with E, maketh a common passage
which is prepared for the nerues.

M, 2, 4, A rough place there where the first rack-bone of the neck wanteth the spine.

AN, 2, 3, The second *vertebra* of the necke whose body bunching in the middest and depressed on either side, 2, in the third figure exhibiteth.

O, 2, 3, 4, The appendix or proceffe of the second
vertebra called the *Tooth*.

P, 2, A hole made of the cavity of that tooth and of the first rack-bone, through which small branches of nerves are transmitted.

2,2, A roughness wherein the hole is not perceived to be thrilled through.

R, 2, The descending proceſſe of the ſecond *vertebra*:

S.2,3, The third *vertebra* of the neck.

T, 2, The descending proceſſe of the third vertebra.

VV, 2, 4. The processes of the racke-bones on the back-side divided thorough the middest.

X, 2, 4, The backward proceſſe of the ſeventh rack-
bone which is not clouen as the former $\beta\beta$.

2, 3, 4, The highest proceſſe of the rack-bones.

Z, 3, 4, The two first extraordinary processes in the highest part of the *vertebra*.

22, 2, The extraordinary part of the laterall proecesses.

FIG. I

From, A, to B, The seven vertebrae of the necke.
 From C, to D, The twelve vertebrae of the chest.
 From E, to F, The five rack-bones of the Loynes.
 From G, to H, The Os sacrum or Holy-bone.
 From I, to K, The bone Coccyx or the rump-bone according to the late writers.
 LL, The bodies of the vertebra.
 M, The transverse processes of the vertebra.
 N, The descendent processes.
 OO, The ascendent processes.
 PP, The backward processes.
 QQ, The holes that are in the sides of the vertebra through which the nerves are transmitted.
 RR, A gristly ligament betwixt the vertebra.
 A, 2, 3, 4, The hole whereout the marrow of the backe issueth.
 B, 2, 3, The cavity which admitteth the root of the second rack-bone.
 C, 3, 4, A cavity or Sinus in the same place crusted over with a gristle.
 D, 2, A prominence in the outward region of this Sinus.
 EF, 2, 3, The Sinus or cavity of the first rack-bone which admitteth the 2. heads of the nowle-bone.
 GG, 2, 3, 4, the transverse processe of the 1. vertebra.
 H, 1, The hole of this transverse processe.
 I, 3, The Sinus, which together with the cavity of the nowle-bone marked with E, maketh a common passage prepared for the nerves.
 K, 3, 4, A rough place where the spine of the first rack is wanting.
 LL, 4, Two cavities of the first rack receiuing the 2. bunches of the second rack marketh with MN.
 MN, 5, 6, The 2. bunches of the second rack which fall into the cavities of the first.

O, 7, The appendix or tooth of the second rack. P, 3, A knub of this appendix crusted over with a gristle. Q, 6, The backside of the tooth. R, 6, the Sinus or cavity of the same, about which a transverse ligament is rowled containing the said tooth in the cavity of the first rack. ST, 6, Certaine cavities at the sides of the tooth whence the roots issue of the fore-branch of the second paire of sinews. V, 5, the point of the tooth. X, 3, An asperity or roughnes where there is a hole but not thrilled through. Y, 6, A cavity of the second rack which together with the cavity marked with Z, maketh a hole, through which the nerves do issue. Z, 4, the Sinus of the first rack. a, 5, 6, 7, the double spine of the second rack. b, 5, 6, 7, the transverse processe of the second rack. c, 7, the hole of the said transverse processe. d, 6, 7, the descending processe of the second rack whose cavity is marked with d, in the 6. figure. e, 6, 7, the place where the body of the second rack descendeth downward. f, gg, 8, the lower side of the body of the third rack at f, the two eminent parts of the same at gg. h, 8, the ascending processes. Im, 8, the two descending processes. n, o, p, q, 8, the transverse processes. r, 8, 9, the spine or the backward processe. st, 8, the two toppes of the spine. u, 9, the descending processe of the third rack. x, 9, the ascending processe. y, the transverse processe of the third rack. z, 8, 9, the hole of this transverse processe. A, 9, the vpper hollowed part of the body of the third rack. B, 9, the Sinus or cavity which maketh the lower part of a hole through which the conigations of the nerves are led. a, 7, the vpper part of the same hole.

processes [tab. 20. fig. 5, 6, 7, b] which are short and obliquely perforated [tab. 2. fig. 7, c] his backward processe byfurcated [tab. 20. fig. 5, 6, 7, a] because of the muscles, and beside his ascending processes lightly bunching out, and his descending [tab. 19. fig. 5, R, tab. 20. fig. 6, 7, d] lightly hollowed; beside all these (I say) there ariseth out of the middle of his body an appendix commonly called a processe which is round and long [tab. 19. fig. 2, 3, 4, O, tab. 20. fig. 6, Q, figure

fig. 7, O] and is called *ὀδοντοειδής* because it is like that tooth of a man which we call the Dog tooth. The surface of this tooth is somewhat rough to giue an originall to a ligament [tab. 19, fig. 5, E] whereby it is tyed to the occipitium: it is also compassed with a round and solide ligament [tab. 19, fig. 5, K] lest the marrow should bee compressed: it is also ioyned with the first by a broad ligament [tab. 20, fig. 5, F] compassing it about.

The third spondell of the necke [tab. 19, fig. 2, 3, SS, tab. 20, fig. 8, 9,] which is called *ἄνω* The 3. spondell (and groweth together very firmly on the fore side with the other foure) as also the 3. following haue their laterall processe bifurcated or forked [tab. 19, fig. 2, VV, fig. 4, 6] because of the implantation of the muscles. But the seventh spondell [tab. 19, fig. 2, 3, 4, character 7,] Seventh. is like the rack-bones of the chest, and his backward processe is not alwayes forked [tab. 19, fig. 2, 4, X] but sometimes whole, the body below is plaine that it may fully ioine with the following vertebra.

All of them (except the first) haue appendices betweene which doe run thicke and soft gristles to make them more nimble and free. Their appendices.

And thus much shall suffice for the bones of the chest in this place; where also we will put an end to the History of the middle belly, and proceede to the Controuersies concerning the same.

A Dilucidation or Exposition of the Controuersies concerning the Chest and Heart, &c.

QUEST. I.

An Anatomical demonstration concerning the Phrensie of the Midriffe.

THe ancient Physicians before *Plato*, did not call the Midriffe *Diaphragma*, but *φρέν*, not because there was in it any seate of wisdom which the Greeke word signifieth, but because when this muscle is inflamed, presently followeth the disease called *Phrenitis* or the Phrensie, which is a continuall abalienation or distemper of the minde, ioyned with an acute feuer and want of rest or sleep. The inflammations of many parts breede this deliration, as of the Liuer, the Stomack and the Lungs; but such distemper is but vncertaine and at sometimes not continuall, onely the inflammation of the midriffe breedeth a perpetuall or continuall phrensie, which so neerely resembleth the true phrensie arising from the inflammation of the brain and his membranes, that it may deceiue a Physicion vnlesse he be right skillfull: we will deliuer in this place the signes how they may bee distinguished. They are therefore discerned the one from the other by respiration, by the voyce, and by the handling of the *Hypochondria*. The true and primary phrensie which commeth from the inflammation of the braine or his membranes, maketh the respiration great, and that is deepe and long, seldome and rare with much distance betweene the breathings: but in the phrensie of the midriffe the respiration is frequent or quicke, small or shallow, because the instrument of respiration is inflamed, so that the chest cannot moue or be enlarged in all his demensions in inspiration, nor yet bee freely collected or gathered vp together in expiration, as it may bee in the former,

Why the midriffe is called *phrenes*.

What is a phrensie.

How the phrensie of the midriffe is distinguished from that of the Liuer, and other parts.

How from the phrensie of the braine.

How by the respiration.

Mm 3

where

where the instrument of breathing is not tainted or violated, but only the braine: So it becoms frequent & quick, often returning, because of the necessity imposed by the flame of the ague for so the shallow breathing is recompenced by often breathing.

How by the
voyce.

Secondly, these phrensies are distinguished by the voyce: for in the phrensie of the braine the voice is base; they cry out, spurne and bite any that comes neere them: contrariwise in the phrensie of the midriffe the voyce is acute or treble, because the chiefe instrument of free respiration is affected, and being drawne vpward by the inflammation, the chest becometh narrower; for the magnitude and basenes of the voyce follows the constitution of this instrument.

How by the
retraction of
the Hypochondria.

The last and most proper signe of this phrensie of the midriffe, Hippocrates deliuereth in the 5. Aphorisme *Concarum praeotionum*, where he saith: In these men their *Hypochondria* appeare *intro sursum reuulsa*. i. to be drawne inward and vpward: the demonstration of which saying is to be made by Anatomy thus: The midriffe in the vpper side is covered with the *pleura*; on the lower with the *Peritoneum* or rim of the belly, which incloseth as in a sacke all the natural instruments and parts contained in the lower belly, and giueth euery one of them his owne coate. The midriffe then being inflamed, is drawn vpward, and raiseth with it the *Peritoneum*: with the *Peritoneum* are the *Hypochondria*, the Liuer, the Spleene, the Stomacke, and all the bowels retracted; and so comes that inward and vpward reuulsion of the *Hypochondria* Hippocrates mentioneth: wherefore these are the three proper and demonstratiue signes of the phrensie from the midriffe: small or shallow and frequent respiration, a shrill or treble voice, and the vpward and inward reuulsion of the *Hypochondria*. But why happeneth it, that when the midriffe is inflamed, there followeth a phrensie? Some thinke that when the midriffe is inflamed, the braine is also presently alike affected; for the inflammation of the midriffe hindering respiration, the heat is increased in the chest and the heart, the blood is attenuated and groweth cholerick and flyeth vp into the braine, whence commeth an *Erysipelas*, that is a cholerick inflammation of the braine, the immediate cause of the true phrensie; but these things are ridiculous. For if it were so, then whensoever the Lungs also are inflamed, presently a perpetuall phrensie would follow, because there followeth both a difficulty of breathing, and the Lungs are nourished with a bilious, that is, a very thin blood: moreover, if an *Erysipelas* should breede in the braine, then were the phrensie a true phrensie, and not depending vpon the inflammation of the midriffe. Others referre the cause of the phrensie to an analogie or proportion in all correspondency betwene the midriffe and the brayne. But because the marrow of the back is more correspondent to the brayne, and yet when that is inflamed, there followeth not alwayes a perpetuall phrensie, wee doe worthily search farther for the cause.

The Anatomical
demonstration.

The three demonstratiue
signes of the
phrensie from
the midriffe.
Why when
the midriffe is
inflamed,
there followeth
a phrensie.

The true cause

We therefore vnderstand that there is a double concurring in this busines, to wit, a wonderfull connexion and society of these two parts, and then the perpetuall motion of the midriffe. The society is by nerues, which communicate both heate and a vaporious spirit to the braine. And the continuall and strong motion of the midriffe drieth vp with force and violence smoaky vapours to the braine. For if you only admitt the society or sympathy of the nerues, why should not the same phrensie fall out when the mouth of the stomacke is inflamed, which hath notable stomachicall sinews which from the braine are inserted into it?

QUEST. II.

Of the motion of the Heart and the Arteries or Pulse, a Philosophicall discourse.

Euery man
carries a perpetuall
motion about him.

He busie wit of man obseruing the perpetuall motions of the heauens, hath long trauelled to imitate the same, and in making experiments, hath framed excellent and admirable peeces of workmanship, whilest euery one carried a perpetuall motion about himselfe, which happily he little remembered or thought vpon, and that is the perpetuall motion of the heart, which from the day of birth, till the day of death, neuer ceaseth, but moueth continually: by what engines and pullies, what poyles and counter-poyles, what affluencies and refluencies this perpetuity is accomplished, we imagine wil neither be vnprofitable nor vnpleasant to vnderstand, especially to those that desire to know and acknowledge the admirable works of God in this little world of the body of man, as well as his great administrations in the greater. We reade of *Aristotle*, that when he was in banishment in *Chalcide*, and obserued the seuen-fold Ebbing and Flowing in one day and a night of the *Euripus* or narrow Frith betwene

The cause of
Arteries, death.

twene *Aulis* and the Iland *Eubaa*, and could not finde out the cause of it, he pyned away euery to death with sorrow. Me thinks therefore that euery man when he put his hand but into his bosome and feeleth there a continuall pulsation, by which he knoweth his owne life is gouerned, should also be desirous to vnderstand what maner of engine this is, which being so small that he may couer it with his hand, hath yet such diuersities of mouing causes therein, especially considering that a little skill to cleere and dresse the wheelles may keepe this watch of his life in motion, which otherwise will furre vp & finally stand in his dissolution. We will therefore a litle payne our selues, to discourse of the manifold difficulties wherein the causes of this motion are so intangled, that some not meere vnclearned haue thought, that they are onely knowne to God and Nature and to none other.

The heart compared to a small watch.

The motion therefore of the heart is double; one naturall, the other depraued. The naturall we call the Pulse, the other we call Palpitation: the one proceedeth from a naturall faculty, the other from an vnaturall distemper: the one is an action of the heart, the other a passion. Our discourse shall be only of the naturall motion which consisteth of a dilatation called *Diastole*, a contraction called *Systole*, and a double rest betweene them.

The motion of the heart double. The Naturall motion.

Aristotle imagined the only cause of this motion to be heate, but perpetuated by the continuall affluence of oylie moisture, which as continually is consumed as it is ministred, euery as oyle put to a lampe: but the dilatation (saith he) commeth from ebullition or boyling of the blood, whereby it riseth and occupieth a larger place, yea and powreth it selfe out into all the caviety adioyning thereto: and this he illustrateth by an example taken from boyling water; water when it boileth riseth vp and occupieth a larger place then it did before, but if you blow cold ayre into it, it presently falleth; right so is it (saith he) in the heart of a man, the heate boyleth vp the blood, and the cold ayre we draw in by inspiration setteth it againe: and this is farther proued because the pulses of yong men are more lively and stronger then of old, of whole men then of sicke, of waking men then of sleeping, because their heate is more vehement, and the feruor or working of their blood more manifest. These things are very probable, and carry (I must needs say) a great shew of trueth, but if they be weighed in the ballance of Anatomy they will bee found but light. Herein was the Philosophers error that hee vnderstandeth the heart to be distended or dilated, because it is filled: contrariwise, the Anatomist vnderstandeth the heart to be filled because it is dilated.

Aristotles conceit of the cause.

A pregnant example.

Another instance.

Wherein was the Philosophers error.

In the depraued motion or palpitation of the heart it is distended indeed, because it is filled either with water or with vapours, but in the proper and naturall it is dilated by an inbred power of his owne, and being dilated drawes in blood and spirits, and so is filled, like as a Smiths bellows being opened by the power of the Smith is filled with ayre whether hee will or no; bladders whilest they are filled are distended, those fill in the dilatation, these dilate in the filling.

Comparison

Beside this conceit of *Aristotles*, others haue diuersly deuised conceits concerning this motion. *Erasistratus*, *Hiracleus*, *Erithreus*, conceived that the motion of the heart was from the Animall and vitall faculties together. *Auerrhoes*, that it was from the appetent and sentient Soule; and that the heat was but the Instrument which the appetite vsed: others thought that nature only moued the heart, because alone it is said to bee *principium motus*, or beginning of motion in those things that are moued: others, that the dilatation of the heart was from the Soule, and the contraction meere naturall, the sides of the heart falling down with their owne waight, like as in the disease called *Tremor*, or the shaking palsie; the faculty of the Soule continually rayseth vp the head, and the waight beareth it downe againe, whence the perpetuall shaking proceedeth.

Erasistratus, *Hiracleus*.

Auerrhoes.

Other opinion.

The cause of the shaking palsie.

But trueth is, the motion of the heart is no trembling but a constant and orderly motion; neither is the contraction caused by the waight of the heart, it buckling vnder the burthen of it selfe, but the greatest strength of the heart is in the contraction, whereby it hurleth forth (as the lightning passeth through the whole Heauen) his spirits into the whole body, and excludeth oftentimes not without violence, the fumed vapours into the Arteriall Veine. But before wee set downe our resolution concerning this matter, a few things are to bee first established.

The kinds of motions.

Voluntary motions.
